PREDGOVOR MULTIKONFERENCI INFORMACIJSKA DRUŽBA 2024

Leto 2024 je hkrati udarno in tradicionalno. Že sedaj, še bolj pa v prihodnosti bosta računalništvo, informatika (RI) in umetna inteligenca (UI) igrali ključno vlogo pri oblikovanju napredne in trajnostne družbe. Smo na pragu nove dobe, v kateri generativna umetna inteligenca, kot je ChatGPT, in drugi inovativni pristopi utirajo pot k superinteligenci in singularnosti, ključnim elementom, ki bodo definirali razcvet človeške civilizacije. Naša konferenca je zato hkrati tradicionalna znanstvena, pa tudi povsem akademsko odprta za nove pogumne ideje, inkubator novih pogledov in idej.

Letošnja konferenca ne le da analizira področja RI, temveč prinaša tudi osrednje razprave o perečih temah današnjega časa – ohranjanje okolja, demografski izzivi, zdravstvo in preobrazba družbenih struktur. Razvoj UI ponuja rešitve za skoraj vse izzive, s katerimi se soočamo, kar poudarja pomen sodelovanja med strokovnjaki, raziskovalci in odločevalci, da bi skupaj oblikovali strategije za prihodnost. Zavedamo se, da živimo v času velikih sprememb, kjer je ključno, da s poglobljenim znanjem in inovativnimi pristopi oblikujemo informacijsko družbo, ki bo varna, vključujoča in trajnostna.

Letos smo ponosni, da smo v okviru multikonference združili dvanajst izjemnih konferenc, ki odražajo širino in globino informacijskih ved: CHATMED v zdravstvu, Demografske in družinske analize, Digitalna preobrazba zdravstvene nege, Digitalna vključenost v informacijski družbi – DIGIN 2024, Kognitivna znanost, Konferenca o zdravi dolgoživosti, Legende računalništva in informatike, Mednarodna konferenca o prenosu tehnologij, Miti in resnice o varovanju okolja, Odkrivanje znanja in podatkovna skladišča – SIKDD 2024, Slovenska konferenca o umetni inteligenci, Vzgoja in izobraževanje v RI.

Poleg referatov bodo razprave na okroglih mizah in delavnicah omogočile poglobljeno izmenjavo mnenj, ki bo oblikovala prihodnjo informacijsko družbo. “Legende računalništva in informatike” predstavljajo slovenski “Hall of Fame” za odlične posameznike s tega področja, razširjeni referati, objavljeni v reviji *Informatica* z 48-letno tradicijo odličnosti, in sodelovanje s številnimi akademskimi institucijami in združenji, kot so ACM Slovenija, SLAIS in Inženirska akademija Slovenije, bodo še naprej spodbujali razvoj informacijske družbe. Skupaj bomo gradili temelje za prihodnost, ki bo oblikovana s tehnologijami, osredotočena na človeka in njegove potrebe.

S podelitvijo nagrad, še posebej z nagrado Michie-Turing, se avtonomna RI stroka vsakoletno opredeli do najbolj izstopajočih dosežkov. Nagrado Michie-Turing za izjemen življenjski prispevek k razvoju in promociji informacijske družbe je prejel prof. dr. Borut Žalik. Priznanje za dosežek leta pripada prof. dr. Sašu Džeroskemu za izjemne raziskovalne dosežke. »Informacijsko limono« za najmanj primerno informacijsko tematiko je prejela nabava in razdeljevanjem osebnih računalnikov ministrstva, »informacijsko jagodo« kot najboljšo potezo pa so sprejeli organizatorji tekmovanja ACM Slovenija. Čestitke nagrajencem!

Naša vizija je jasna: prepoznati, izkoristiti in oblikovati priložnosti, ki jih prinaša digitalna preobrazba, ter ustvariti informacijsko družbo, ki bo koristila vsem njenim članom. Vsem sodelujočim se zahvaljujemo za njihov prispevek k tej viziji in se veselimo prihodnjih dosežkov, ki jih bo oblikovala ta konferenca.

Mojca Ciglarič, predsednica programskega odbora

Matjaž Gams, predsednik organizacijskega odbora

PREFACE TO THE MULTICONFERENCE INFORMATION SOCIETY 2024

The year 2024 is both ground-breaking and traditional. Now, and even more so in the future, computer science, informatics (CS/I), and artificial intelligence (AI) will play a crucial role in shaping an advanced and sustainable society. We are on the brink of a new era where generative artificial intelligence, such as ChatGPT, and other innovative approaches are paving the way for superintelligence and singularity—key elements that will define the flourishing of human civilization. Our conference is therefore both a traditional scientific gathering and an academically open incubator for bold new ideas and perspectives.

This year's conference analyzes key CS/I areas and brings forward central discussions on pressing contemporary issues—environmental preservation, demographic challenges, healthcare, and the transformation of social structures. AI development offers solutions to nearly all challenges we face, emphasizing the importance of collaboration between experts, researchers, and policymakers to shape future strategies collectively. We recognize that we live in times of significant change, where it is crucial to build an information society that is safe, inclusive, and sustainable, through deep knowledge and innovative approaches.

This year, we are proud to have brought together twelve exceptional conferences within the multiconference framework, reflecting the breadth and depth of information sciences:

- CHATMED in Healthcare
- Demographic and Family Analyses
- Digital Transformation of Healthcare Nursing
- Digital Inclusion in the Information Society – DIGIN 2024
- Cognitive Science
- Conference on Healthy Longevity
- Legends of Computer Science and Informatics
- International Conference on Technology Transfer
- Myths and Facts on Environmental Protection
- Data Mining and Data Warehouses – SIKDD 2024
- Slovenian Conference on Artificial Intelligence
- Education and Training in CS/IS.

In addition to papers, roundtable discussions and workshops will facilitate in-depth exchanges that will help shape the future information society. The “Legends of Computer Science and Informatics” represents Slovenia’s “Hall of Fame” for outstanding individuals in this field. At the same time, extended papers published in the Informatica journal, with over 48 years of excellence, and collaboration with numerous academic institutions and associations, such as ACM Slovenia, SLAIS, and the Slovenian Academy of Engineering, will continue to foster the development of the information society. Together, we will build the foundation for a future shaped by technology, yet focused on human needs.

The autonomous CS/IS community annually recognizes the most outstanding achievements through the awards ceremony. The Michie-Turing Award for an exceptional lifetime contribution to the development and promotion of the information society was awarded to Prof. Dr. Borut Žalik. The Achievement of the Year Award goes to Prof. Dr. Sašo Džeroski. The "Information Lemon" for the least appropriate information topic was given to the ministry's procurement and distribution of personal computers. At the same time, the "Information Strawberry" for the best initiative was awarded to the organizers of the ACM Slovenia competition. Congratulations to all the award winners!

Our vision is clear: to recognize, seize, and shape the opportunities brought by digital transformation and create an information society that benefits all its members. We thank all participants for their contributions and look forward to this conference's future achievements.

KAZALO / TABLE OF CONTENTS

Slovenska konferenca o umetni inteligenci / Slovenian Conference on Artificial Intelligence ***1***

PREDGOVOR / FOREWORD 3

PROGRAMSKI ODBORI / PROGRAMME COMMITTEES 5

PandaChat-RAG: Towards the Benchmark for Slovenian RAG Applications / Kuzman Taja, Pavleska Tanja, Rupnik Urban, Cigoj Primož 7

Choosing Features for Stress Prediction with Machine Learning / Bengeri Katja, Lukan Junoš, Luštrek Mitja 11

Predictive Modeling of Football Results in the WWIN League of Bosnia and Herzegovina / Vladić Ervin, Mehanović Dželila, Avdić Elma 15

Sarcasm Detection in a Less-Resourced Language / Đoković Lazar, Robnik-Šikonja Marko 19

Speech-to-Service: Using LLMs to Facilitate Recording of Services in Healthcare / Smerkol Maj, Susič Rok, Ratajec Mariša, Halbwachs Helena, Gradišek Anton 23

Performance Comparison of Axle Weight Prediction Algorithms on Time-Series Data / Kolar Žiga, Susič David, Konečnik Martin, Prestor Domen, Pejanovič Nosaka Tomo, Kulauzović Bajko, Kalin Jan, Skobir Matjaž, Gams Matjaž 27

Comparison of Feature- and Embedding-based Approaches for Audio and Visual Emotion Classification / Trojer Sebastijan, Anžur Zoja, Luštrek Mitja, Slapničar Gašper 31

Multi-modal Data Collection and Preliminary Statistical Analysis for Cognitive Load Assessment / Krstevska Ana, Kramar Sebastjan, Gjoreski Hristijan, Gjoreski Martin, Lukan Junoš, Trojer Sebastijan, Luštrek Mitja, Slapničar Gašper 35

Predicting Health-Related Absenteeism with Machine Learning: A Case Study / Piciga Aleksander, Kukar Matjaž 39

Puzzle Generation for Ultimate-Tic-Tac-Toe / Zirkelbach Maj, Sadikov Aleksander 43

Ethical Consideration and Sociological Challenges in the Integration of Artificial Intelligence in Mental Health Services / Poljak Lukek Saša 47

Optimization Problem Inspector: A Tool for Analysis of Industrial Optimization Problems and Their Solutions / Tušar Tea, Cork Jordan, Andova Andrejaana, Filipič Bogdan 51

Multi-Agent System for Autonomous Table Football: A Winning Strategy / Založnik Marcel, Šoln Kristjan 55

Towards a Decision Support System for Project Planning: Multi-Criteria Evaluation of Past Projects Success / Hafner Miha, Bohanec Marko 59

Minimizing Costs and Risks in Demand Response Optimization: Insights from Initial Experiments / Nedić Mila, Tušar Tea 63

Predicting Hydrogen Adsorption Energies on Platinum Nanoparticles and Surfaces With Machine Learning / Gašparič Lea, Kokalj Anton, Džeroski Sašo 67

SmartCHANGE Risk Prediction Tool: Demonstrating Risk Assessment for Children and Youth / Jordan Marko, Reščič Nina, Kramar Sebastjan, Založnik Marcel, Luštrek Mitja 71

Predicting Mental States During VR Sessions Using Sensor Data and Machine Learning / Kizhevska Emilija, Luštrek Mitja 75

Biomarker Prediction in Colorectal Cancer Using Multiple Instance Learning / Shulajkovska Miljana, Jelenc Matej, Jonnagaddala Jitenndra, Gradišek Anton 79

Feature-Based Emotion Classification Using Eye-Tracking Data / Božak Tomi, Luštrek Mitja, Slapničar Gašper 83

Kognitivna znanost / Cognitive Science ***87***

PREDGOVOR / FOREWORD 89

PROGRAMSKI ODBORI / PROGRAMME COMMITTEES 91

The Ontological Shock: What Psychedelics can Teach us about the Nature of the Mind / Sirk Maruša 93

Innovative Supporting Approaches: Integrating Bibliotherapy, Psychodrama and AI as a Therapeutic Conversational Tool / Mattová Veronika, Lazore Courtney 98

Usability of Intelligent Assistive Technology Used by People With Dementia and Their Caregivers / Dečman Klara 102

Open Science and Goodhart's Law / Pisanski Tomaž, Batagelj Vladimir, Pisanski Jan 106

The Consistency of the Research Field Data: A Case Study of Library and Information Science in Slovenia / Pisanski Jan 110
To Be or Not to Be… a Nahuatl Language Learning App. The Long-Term Survival or Discontinuation of Indigenous Language Learning Apps on the Example of Nahuatl / Fischer Evelyn 113
Designing the Flow State Experience Using Modern Digital Technologies / Vidmar Eva 117
The Transparency of Nudging: Evaluating Its Impact on Personal Autonomy / Pajmon Sabina, Strle Toma 121
Does the Use of Large Language Models in Scientific Research Bring Us Closer to the Point in Time When Machines Will Dominate Humans? / Mali Franc 125
Comparing Academic Performance Across Course Topics: A Pilot Study / Fink Laura, Cestnik Bojan 130
Linking the Normative and the Descriptive: Bounded Epistemic Rationality / Tomat Nastja 136
Exploring Human Perception Using Virtual Reality / Zibrek Katja 141
Vpliv generativne umetne inteligence na demokracijo / Košmrlj Lea, Bratko Ivan 145
Razložljiva umetna inteligenca: kako naprej? / Farič Ana, Bratko Ivan 150
Exploring Cognitive Science under Analytical Idealism / Rodman Grega 155
Intelligent Revolution – a New Civilization and Cognitive Era / Gams Matjaž 158
Cognitive Perspective on Production of Third Person Dative and Accusative Clitic Pronouns in Slovenian School-Aged Children / Brežnik Dornik Maruša 164
Ballot Butts: Nudging towards Pro Environmental Behaviour / Hartmans Anouk, Karnelutti Lucija, Žužek Leon, Strle Toma, Pajmon Sabina 167
Problem Solving as a Key for Sustainable Future / Štibi Ivana, Gaurina Marija, Katavić Ivana, Stepanić Josip 171
Mind, the Gap, and Other Cracks / Poljšak Kus Maša, Kordeš Urban 175
Bridging the Challenges in Experience Sampling Research / Seme Barbi, Sirk Maruša, Kordeš Urban 179

Odkrivanje znanja in podatkovna skladišča - SiKDD / Data Mining and Data Warehouses - SiKDD 183
PREDGOVOR / FOREWORD 185
PROGRAMSKI ODBORI / PROGRAMME COMMITTEES 187
Integrating Knowledge Graphs and Large Language Models for Querying in an Industrial Environment / Kenda Klemen, Hočevar Domen 189
Comparative Analysis of Machine Learning Models for Groundwater Level Forecasting: The Impact of Contextual Data / Klančič Rok, Kenda Klemen 193
Interactive Tool for Tracking Open-source Artificial Intelligence Progress on Hugging Face / Šinik Bogdan, Vake Domen, Vičić Jernej, Tošić Aleksander 197
Multilingual Hate Speech Modeling by Leveraging Inter-Annotator Disagreement / Grigor Patricia-Carla, Kralj Novak Petra, Evkoski Bojan 201
Predicting Pronunciation Types in the Sloleks Morphological Lexicon of Slovene / Čibej Jaka 205
Higher-order bibliographic services based on bibliographic networks / Batagelj Vladimir, Pisanski Jan, Pisanski Tomaž 209
Are papers all that counts? A bibliometric analysis of the Slovenian scientific community / Dupuis Aymeric, Džeroski Sašo, Koloski Boshko, Martinc Matej 213
Empowering Open Education Methodologies with AI-based Strategies for the Customization of Education / Amiel Tel, Mores Neto Antonio J., Pita Costa Joao, Polajnar Anja, Jermol Mitja 217
Addressing Water Sustainability Challenges in North Africa with Artificial Intelligence / Zaouini Mustafa, Pita Costa Joao, Cherakaoui Manal, Hachimi Hanaa, Abkari M. Wahib, Gourari Kamal, Lachheb Hatim, Tounsi El Azzoiani Jad 221
Predicting poverty using regression / Urbanč Luka, Grobelnik Marko, Pita Costa Joao 225
Fact Manipulation in News: LLM-Driven Synthesis and Evaluation of Fake News Annotation / Golob Luka, Sittar Abdul 229
Borrowing Words: Transfer Learning for Reported Speech Detection in Slovenian News Texts / Fijavž Zoran 233
Connecting company performance to ESG terms in financial reports / Andrenšek Luka, Sitar Šuštar Katarina, Pollak Senja, Purver Matthew 237
Classification of Patents Into Knowledge Fields: Using a Proposed Knowledge Mapping Taxonomy (KnowMap) / Motamedi Elham, Novalija Inna, Rei Luis 241

Enhancing causal graphs with domain knowledge: matching ontology concepts between ontologies and raw text data / Stegnar Jernej, Rožanec Jože M., Leban Gregor, Mladenić Dunja 245
Measuring and Modeling CO2 Emissions in Machine Learning Processes / Hrib Ivo, Šturm Jan, Topal Oleksandra, Škrjanc Maja 249
Enhancing Ontology Engineering with LLMs: From Search to Active Learning Extensions / Kholmska Ganna, Kenda Klemen, Rožanec Jože M. 255
On the Brazilian Observatory for Artificial Intelligence / Meira Silva Rafael, Godoy Oliveira Cristina, Costa Luiz, Candia Vieira Joao Paulo, Pita Costa Joao 259
Pojavljanje incidentov ob uporabi Umetne Inteligence / Grobelnik Marko, Massri M. Besher, Guček Alenka, Mladenić Dunja 263
Perception of AI in Slovenia / Sittar Abdul, Guček Alenka, Mladenić Dunja 267
Naslov / Šker Tesia, Rožanec Jože M., Leban Gregor, Mladenić Dunja 271
Generating Non-English Synthetic Medical Data Sets / Dolinar Lenart, Calcina Erik, Novak Erik 275
LLNewsBias: A Multilingual News Dataset for Lifelong Learning / Swati, Mladenić Dunja 279
Creating Local World Models using LLMs / Longar Mark David, Novak Erik, Grobelnik Marko 283
Semantic video content search and recommendation / Longar Mark David, Fir Jakob, Pangeršič Bor 287
Continuous Planning of a Fleet of Shuttle Vans as Support for Dynamic Pricing / Stavrov Filip, Stopar Luka 291
Knowledge graph Extraction from Textual data using LLM / Gilliani Khasa, Novak Erik, Kenda Klemen, Mladenić Dunja 295
Solving hard optimization problems of packing, covering, and tiling via clique search / Szabo Sandor, Zavalnij Bogdan 299

Miti in resnice o varovanju okolja / Myths and Truths About Environmental Protection 303
PREDGOVOR / FOREWORD 305
PROGRAMSKI ODBORI / PROGRAMME COMMITTEES 307
LCA data conforms to Benford's law / Šinik Bogdan, Tošić Aleksander 309
Liquid Neural Network in Modelling Rainfall-Runoff Modelling / Teklu Henok, Gams Matjaž, Wielgosz Maciej 313
The governance of cultural landscapes in the EU: A Comparative Analysis of the Nature Restoration Law and the LULUCF Regulations / Schenk Richard 317
Serious Errors in the Assessment of the Atmospheric Greenhouse Effect / Margan Erik 321
Vrednost električne energije intermitirajočih virov in kanibalizem na trgu z električno energijo / Mihalič Rafael 329
Kako razumeti ogljični odtis? / Radonjič Gregor 336
Ali je prispevek slovenske živinoreje k podnebnim spremembam precenjen? / Verbič Jože 339
Oblikovanje specifičnih habitatov kot ukrepanje za zmanjšanje vplivov hidroelektrarn na okolje / Hribar Andraž 343
Aksiomi in miti o varovanju okolja in trajnostnem kmetijstvu / Gams Matjaž 349
Umetna inteligenca o zeleni agendi / Špiler Jure 356
Radon v stavbah in kakovost bivanja / Valenčič Matjaž 364
Postavljanje sončnih elektrarn na kmetijskih površinah - okoljski kriminal ali trajnostna raba prostora / Valenčič Matjaž 369
Skrivnost ljubljanske pitne vode in kanal C0 / Ogrin Tomaž 375
Kakšna je cena jedrske energije in obnovljivih virov in kakšen je vpliv na okolje / Trkov Andrej 381
O statusu in prihodnosti jedrske energije / Cizelj Leon 384
Natura 2000 in ohranjanje narave, spodbude ali ovire pri razvoju elektroenergetskega omrežja / Kregar Aleš 388
Sprejemljive in „nesprejemljive" metode žlahtnjenja rastlin kot del boja za racionalno odločanje v okoljevarstvu / Bohanec Borut 393
No fossil fuels - no food / Senegačnik Andrej 395
Nemški energetski prehod ter njegove politične in gospodarske posledice / Povh Dušan 399
Miti in resnice o elektromagnetnem sevanju / Lipič Karel 402

17. Mednarodna konferenca o prenosu tehnologij / 17th International Technology Transfer Conference *407*
PREDGOVOR / FOREWORD 409
PROGRAMSKI ODBORI / PROGRAMME COMMITTEES 411
Intellectual Property as a Success Factor for Startups: Systematic Literature Review / Fortun Novak Maja 413
The Reversed European Paradox: do European Patents have a High Market Value but Low Impact? / Hafner Ana 416
The Importance of Technology Transfer Offices in University Industry Collaboration: KTÜ TTM Example / İskender Balaban Dilek, Değermenci Beril, Yüksel Harun, Yilmaz Eren, Kalyoncu Sedanur, Ayvaz Emrah, Yildiz Oktay, Aykut Yalçın, Yildiz İslam, Sağlam Gözde, Ünver Müslüm Serhat, Sabir Hülya, Sönmez Kerim, Gültekin Güler Tuğba, Aydin Aleyna 420
The Impact of International Networks on Grants, R&D, Knowledge and Technology Transfer – Case of COST Network and KTU / Kalyoncu Sedanur, Yildiz İslam, Ayvaz Emrah, Sağlam Gözde, Ünver Müslüm Serhat, Yildiz Oktay, Gültekin Güler Tuğba, Yilmaz Eren, Sönmez Kerim, Sabir Hülya, Değermenci Beril, Aykut Yalçın, Koç Ayhan, İskender Balaban Dilek, Aydin Aleyna, Baş Seda 424
The Effect of Evaluating Graduate Thesis Topics as Invention Notification Form on Industrial and Intellectual Property Applications: The Case of Karadeniz Technical University / Sönmez Kerim, Ayvaz Emrah, Sabir Hülya, Değermenci Beril, Kalyoncu Sedanur, Yildiz İslam, Ünver Müslüm Serhat, Aykut Yalçın, Sağlam Gözde, Yilmaz Eren, Aydin Aleyna, İskender Balaban Dilek, Gültekin Güler Tuğba, Koç Ayhan, Yildiz Oktay 428

PREDGOVOR

Umetna inteligenca doživlja neverjeten in pospešen razvoj, ko se po tričetrt stoletja, ko je Alan Mathison Turing postavil temelje računalništva in umetne inteligence, končno približuje ne le človeški inteligenci, temveč tudi drugim ključnim človeškim lastnostim, kot sta ustvarjalnost, čustvena inteligenca in zavest. Na številnih področjih umetna inteligenca že presega zmogljivosti večine ljudi in celo strokovnjakov. Veliki jezikovni modeli dosegajo tovrstne rezultate tudi pri dosti manj strukturiranih problemih, kot je bilo predstavljivo pred nekaj leti, npr. pri strokovnih izpitih ter besedilnih nalogah iz matematike in programiranja.

Generativna umetna inteligenca že zdaj spreminja svet. Postala je nepogrešljivo orodje v poslovnem svetu, raziskavah in vsakdanjem življenju, saj omogoča pisanje besedil, ustvarjanje kode, generiranje slik in reševanje kompleksnih problemov. Možno je celo, da smo priča začetkom singularnosti – prelomnega trenutka, ko bo umetna inteligenca presegla človeško inteligenco in omogočila revolucijo na področju produktivnosti in inovacij, čeprav bo treba na sodbo o tem še počakati. Optimizem glede prihodnosti je utemeljen: če se bo razvoj nadaljeval s trenutnim tempom, si lahko predstavljamo svet, kjer bo umetna inteligenca povsem preoblikovala gospodarstvo, znanost in način življenja, pri čemer bo omogočila višjo kakovost življenja za vse.

Čeprav nekateri umetno inteligenco vidijo kot grožnjo, njen trenutni razmah resnejših težav še ni prinesel. Nadejamo se, da bo zadosten del raziskav usmerjen v varnost umetne inteligence, da bo tako ostalo. Z morebitnimi škodljivimi učinki umetne inteligence se spopadajo tudi regulatorji, za katere upamo, da bodo uspešno krmarili med tem ciljem in pretiranim zaviranjem razvoja.

Dostopnost velikih jezikovnih modelov, kot so GPT-ji, pomeni, da so naloge, ki zahtevajo razumevanje in generiranje naravnega jezika, lažje kot kadar koli prej. Mnogi raziskovalci verjamejo, da bo prihodnost programiranja prešla iz tradicionalnih jezikov, kot je Python, na velike jezikovne modele, kjer bo umetna inteligenca generirala kodo in rešitve po meri. Čeprav je razvoj teh modelov zahtevna naloga, ki presega zmožnosti večine organizacij, se ljudje navajamo na uporabo tega fenomenalnega orodja. Pričakujemo, da bo umetna inteligenca postala učinkovit in zanesljiv partner človeštva.

Že letos vidimo, da so konference v sklopu Informacijske družbe posvečene prav velikim jezikovnim modelom. V okviru Slovenske konference o umetni inteligenci organiziramo formalno debato dijakov – izkušenih debaterjev, ki se udeležujejo mednarodnih tekmovanj – o tem, kako bo umetna inteligenca oblikovala prihodnost in zakaj bi to lahko bila najboljša prihodnost doslej.

FOREWORD

Artificial intelligence is experiencing incredible and accelerated development. After three-quarters of a century since Alan Mathison Turing laid the foundations of computing and artificial intelligence, it is finally approaching not only human intelligence but also other key human traits such as creativity, emotional intelligence and consciousness. In many areas, artificial intelligence already surpasses the capabilities of most people and even experts. Large language models are achieving such results even in much less structured problems than was imaginable a few years ago, such as professional exams, and mathematics and programming tasks described in free text.

Generative artificial intelligence is already transforming the world. It has become an indispensable tool in the business world, research, and everyday life, enabling text writing, code generation, image creation, and solving complex problems. It is even possible that we are witnessing the beginnings of the singularity—the pivotal moment when artificial intelligence will surpass human intelligence and enable a revolution in productivity and innovation, although time will show whether this is actually the case. Optimism about the future is well-founded: if development continues at its current pace, we can imagine a world where artificial intelligence completely transforms the economy, science, and way of life, leading to a higher quality of life for all.

Although some see artificial intelligence as a threat, its current rapid progress has not yet led to serious problems. We hope that a sufficient part of the research will be directed towards AI safety so that this remains the case. Regulators are also addressing the potential harmful effects of artificial intelligence, and we hope they will successfully navigate between this goal and excessive hindering of development.

The accessibility of large language models, such as GPTs, means that tasks requiring the understanding and generation of natural language are easier than ever before. Many researchers believe that the future of programming will shift from traditional languages, like Python, to large language models, where artificial intelligence will generate custom code and solutions. Although developing these models is a challenging task beyond the capabilities of most organizations, people are getting accustomed to using this phenomenal tool. We expect artificial intelligence to become an effective and reliable partner for humanity.

Already this year, we are seeing conferences within the framework of the Information Society dedicated to large language models. As part of the Slovenian Conference on Artificial Intelligence, we are organizing a formal debate for high school students—experienced debaters who participate in international competitions—on how artificial intelligence will shape the future and why this might be the best future yet.

Abstract

Retrieval-augmented generation (RAG) is a recent method for enriching the large language models' text generation abilities with external knowledge through document retrieval. Due to its high usefulness for various applications, it already powers multiple products. However, despite the widespread adoption, there is a notable lack of evaluation benchmarks for RAG systems, particularly for less-resourced languages. This paper introduces the PandaChat-RAG – the first Slovenian RAG benchmark established on a newly developed test dataset. The test dataset is based on the semi-automatic extraction of authentic questions and answers from a genre-annotated web corpus. The methodology for the test dataset construction can be efficiently applied to any of the comparable corpora in numerous European languages. The test dataset is used to assess the RAG system's performance in retrieving relevant sources essential for providing accurate answers to the given questions. The evaluation involves comparing the performance of eight open- and closed-source embedding models, and investigating how the retrieval performance is influenced by factors such as the document chunk size and the number of retrieved sources. These findings contribute to establishing the guidelines for optimal RAG system configurations not only for Slovenian, but also for other languages.

Keywords

retrieval-augmented generation, RAG, embedding models, large language models, LLMs, benchmark, Slovenian

1 Introduction

The advent of large language models (LLMs) has introduced significant advancements in the field of natural language processing (NLP). Although LLMs have shown impressive capabilities in generating coherent text, they are prone to hallucinations [7, 16], i.e., providing false information. Furthermore, they are dependent on static and potentially outdated corpora [9]. Retrieval-augmented generation (RAG) is a method devised to address these challenges by augmenting LLMs with external information retrieved from a provided document collection. Connecting LLMs with a relevant database improves the factual accuracy and temporal relevance of the generated responses. Moreover, RAG contributes to the explainability of the generated answers by providing verifiable sources, which facilitates the evaluation of the system's accuracy [2]. These advantages have spurred quick adoption of RAG systems across various applications. For instance, PandaChat[1] leverages RAG to provide explainable responses with high accuracy in Slovenian and other languages, integrated in customer service bots and platforms that allow LLM-based retrieval of information from texts.

Although RAG benchmarking is a relatively recent endeavor, some initial frameworks have already emerged [3, 5, 7]. However, these benchmarks are only limited to English and Chinese, leaving a gap in the evaluation of RAG systems for other languages. To address this gap, we make the following contributions:

- We present the first benchmark for RAG systems for the Slovenian language. The benchmark is based on the newly developed PandaChat-RAG-sl test dataset[2], which comprises authentic questions, answers and source texts.
- We introduce a methodology for an efficient semi-automated development of RAG test datasets that is easily replicable for the languages included in the MaCoCu [1] and CLASSLA-web corpora collections [10], which include all South Slavic languages, Albanian, Catalan, Greek, Icelandic, Maltese, Ukrainian and Turkish.
- As the first step of RAG evaluation, we evaluate the retriever's performance in terms of its ability to provide relevant sources crucial to retrieve accurate answers to the posed questions. The evaluation encompasses comparison of performance of several open- and closed-source embedding models. Furthermore, we provide insights on the impact of the document chunk size and the number of retrieved sources, to identify optimal configurations of the indexing and retrieval components for robust and accurate retrieval.

The paper is organized as follows: in Section 2, we provide an introduction to the previous research concerning the evaluation of RAG systems; Section 3 introduces the PandaChat-RAG-sl dataset (Section 3.1) and the RAG system architecture (Section 3.2), which is evaluated in Section 4. Finally, in Section 5, we conclude the paper with a discussion of the main findings and suggestions for future work.

2 Related Work

Despite the recent introduction of the RAG architecture, several benchmarking initiatives have already emerged [3, 5, 7, 15]. However, since the RAG systems can be applied to various end tasks, the benchmarks focus on different aspects of these systems. Inter

alia, current benchmarks assess their performance in text citation [7], text continuation, question-answering with support of external knowledge, hallucination modification, and multi-document summarization [12].

The closest to our work is the evaluation of the RAG systems on the task of Attributable Question Answering [2]. This task involves providing a question as input to the system, which then generates both an answer and an attribution, indicating the source text on which the answer is based. The advantage of this task over the closed-book question-answering task is that it also measures the system's capability to provide the correct source.

The majority of RAG benchmarks assess RAG systems in English [3, 5, 7, 15] or Chinese [5, 12]. Consequently, the generalizability of their findings to other languages remains uncertain. Furthermore, a limitation of many benchmarks is their reliance on synthetic data generated by LLMs [5, 12, 15]. To avoid potential biases introduced by LLMs and to better represent the complexity and diversity of real-world language use, a more reliable evaluation would be based on non-synthetic test datasets. Despite focusing on a different task, recent research [6] has shown that resource-efficient development of non-synthetic and non-machine translated question-answering datasets is feasible by leveraging the availability of general web corpora and genre classifiers.

3 Methodology

3.1 PandaChat-RAG-sl Dataset

The PandaChat-RAG-sl dataset comprises questions, answers, and the corresponding source texts that encompass the answers. It was created through a semi-automated process involving the extraction of texts from the Slovenian web corpus CLASSLA-web.sl 1.0 [11], followed by a manual extraction of high-quality instances. Since the texts were automatically extracted from a general text collection, the dataset encompasses a diverse range of topics that were not predefined or decided upon.

The CLASSLA-web.sl 1.0 corpus is a collection of texts, collected from the web in 2021 and 2022 [10]. It was chosen due to its numerous advantages: 1) it has high-quality content, with the majority of texts meeting the criteria for publishable quality [17]; 2) it is one of the largest and most up-to-date collections of Slovenian texts, comprising approximately 4 million texts; 3) the texts are enriched with genre labels, facilitating genre-based text selection; and 4) it is developed in the same manner as 6 other CLASSLA-web corpora [10] and 7 additional MaCoCu web corpora in various European languages [1]. This enables easy expansion of the benchmark to other languages, including all South Slavic languages and various European languages, such as Albanian, Catalan, Greek, Icelandic, Ukrainian and Turkish.

The development of the PandaChat-RAG-sl dataset involves the following steps: 1) the genre-based selection of texts from the CLASSLA-web.sl corpus; 2) the extraction of texts that comprise paragraphs ending with a question (80,215 texts); 3) the extraction of questions and answers (paragraphs, following the question); 4) a manual review process to identify high-quality instances. In the genre-based selection phase, we extract texts labeled with genres that are most likely to contain objective questions and answers, that is, *Information/Explanation*, *Instruction* and *Legal*.

In its present iteration, the dataset consists of 206 instances derived from the first 1,800 extracted texts. It is important to note that this effort can easily be continued with further manual inspection of the extracted texts should there be a need to prepare a larger dataset.

Table 1: Statistics for the PandaChat-RAG-sl dataset.

	Number
Instances	206
Unique texts	160
Words (questions)	1,184
Words (texts w/o questions)	83,467
Total words (questions + texts)	84,651

Table 1 provides the statistical overview for the PandaChat-RAG-sl dataset. The dataset consists of 206 instances, that is, triplets of a question, an answer and a source text, derived from 160 texts. The total size of the dataset is 84,651 words, encompassing both the questions and the texts containing the answers.

3.2 RAG System

The RAG pipeline encompasses three main components: indexing, retrieval, and text generation. During the indexing phase, the user-provided text collection is transformed into a database of numerical vectors (embeddings) to facilitate document retrieval by the retriever. This process involves segmenting the documents into fixed-length chunks, which are then converted into embeddings using large language models. The choice of the embedding model and the chunk size are critical factors that can significantly impact the retrieval performance of the model. Selecting an appropriate embedding model is essential to ensure that the textual information is converted into a meaningful numerical representation for effective retrieval. Moreover, the chunk size, in terms of the number of tokens, plays a crucial role in determining the informativeness of the embeddings. Incorrect chunk sizes may lead to numerical vectors that lack important information necessary for connecting the question to the corresponding text chunk, thereby compromising retrieval accuracy [12].

When presented with a question, the retrieval component uses the semantic search (also known as dense retrieval) to retrieve the most relevant text chunks. The search is based on determining the smallest cosine distance between the chunk vectors and the question vector. Lastly, during the text generation phase, the retriever provides the large language model (LLM) with a selection of top retrieved sources. The LLM is prompted to provide a human-like answer to the provided question based on the retrieved text sources. The selection of an appropriate number of top retrieved sources is crucial in this phase: including more than just one retrieved source may enhance retrieval accuracy and address situations where the first retrieved source fails to encompass all relevant information, especially in the case when more texts cover the same subject matter. However, increasing the number of sources also leads to a longer prompt provided to the LLM, potentially increasing the costs of using the RAG system.

In this study, we assess the indexing and retrieval components, focusing on the impact of different embedding models, chunk sizes, and the number of retrieved sources on retrieval performance.

Embedding Models. The evaluation includes a range of multilingual open-source and closed-source models. The selection of open-source models is based on the Massive Text Embedding

Benchmark (MTEB) Leaderboard[3] [13]. Specifically, we choose medium-sized multilingual models with up to 600 million parameters that have demonstrated strong performance on Polish and Russian – Slavic languages that are linguistically related to Slovenian. The models used in the evaluation are:

- Closed-source embedding models provided by the OpenAI: an older model text-embedding-ada-002 (OpenAI-Ada) [8], and two recently published models: text-embedding-3-small (OpenAI-3-small), and text-embedding-3-large (OpenAI-3-large) [14].
- Open-source embedding models, available on the Hugging Face repository: BGE-M3 model [4], base-sized mGTE model (mGTE-base) [19], and small (mE5-small), base (mE5-base) and large sizes (mE5-large) of the Multilingual E5 model [18].

Chunk size. The impact of the chunk size on retrieval performance is assessed by varying chunk sizes of 128, 256, 512, and 1024 tokens, with a default chunk overlap of 20 tokens. In these experiments, the performance is evaluated based on the first retrieved source.

Number of retrieved sources. Previous work indicates that increasing the number of retrieved sources improves the retrieval accuracy [12]. In this study, we examine the retrieval accuracy of embedding models, with a chunk size set to 128 tokens, when the models retrieve 1 to 5 sources. In this scenario, if any of the multiple retrieved sources matches the correct source, the output is evaluated as being correct.

The retrieval capabilities of the RAG system are evaluated on the task of Attributed Question-Answering. The evaluation is based on accuracy, measured as the percentage of questions correctly matched with the relevant source.

The experiments are performed using the LlamaIndex library[4]. The chunk size is defined using the SentenceSplitter method in the indexing phase. Number of retrieved sources (*similarity top k*), the embedding model and the prompt for the LLM model are specified as parameters of the chat engine. The closed-source embedding models are used via the OpenAI API, while the experiments with the open-source models are conducted on a GPU machine.

4 Experiments and Results

In this section, we present the results of the experiments examining the impact of the chunk size, the number of retrieved sources, and the selection of the embedding model on the retrieval performance of the RAG system.

4.1 Chunk Size

Figure 1 shows the impact of the chunk size on the retrieval performance of the RAG systems that are based on different embedding models. The findings suggest that, with the exception of the OpenAI-Ada model, all systems demonstrate the best performance when the text chunk size is set to 128 tokens. Increasing the chunk size hinders the retrieval performance, which is consistent with previous research [12]. These results confirm that smaller chunk sizes enable the embedding models to capture finer details that are essential for retrieving the most relevant text for the given question.

[3]https://huggingface.co/spaces/mteb/leaderboard
[4]https://www.llamaindex.ai/

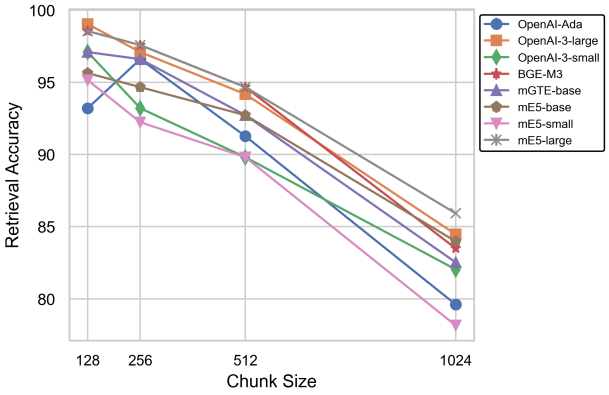

Figure 1: The impact of the chunk size on the retrieval performance.

4.2 Number of Retrieved Sources

Figure 2 shows the performance of the RAG systems when increasing the number of retrieved sources. The results demonstrate that increasing the number of retrieved sources initially improves the performance, however, after a certain threshold, the performance levels off.

Increasing the number of retrieved sources results in larger inputs to the LLM in the text generation component, incurring higher costs. Using more than two retrieved sources does not significantly improve results in most systems. What is more, with the top two retrieved sources, certain embedding models, namely, BGE-M3 and mE5-large, already reach perfect accuracy. Thus, our findings indicate that using more than the top two retrieved sources is unnecessary.

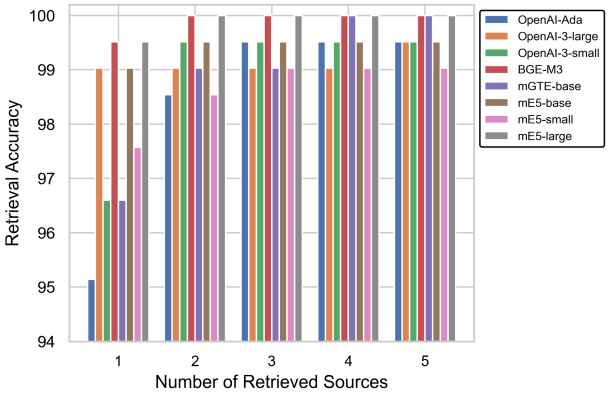

Figure 2: Impact of the number of retrieved sources on the retrieval performance.

4.3 Embedding Models

We provide the final comparison of the performance of systems that use different embedding models. We use the parameters that have shown to provide the best results in the previous experiments: the chunk size of 128 tokens and top two retrieved sources. As shown in Table 2, the retrieval systems that use the open-source BGE-M3 and mE5-large embedding models achieve the perfect retrieval score. They are closely followed by the closed-source OpenAI-3-small and the mE5-base models which achieve

Table 2: Performance comparison between the open-source and closed-source embedding models.

embedding model	speed (s)	retrieval accuracy
BGE-M3	0.58	100
mE5-large	0.58	100
OpenAI-3-small	0.69	99.51
mE5-base	0.29	99.51
OpenAI-3-large	1.19	99.03
mGTE-base	0.31	99.03
OpenAI-Ada	0.63	98.54
mE5-small	0.15	98.54

accuracy of 99.5%. While having slightly lower scores, all other retrieval systems still achieve high performance, ranging between 98.5% and 99% in accuracy.

Additionally, Table 2 provides the inference speed of the models measured in seconds per instance. If inference speed is a priority, the mE5-base model emerges as the optimal selection, as it yields high retrieval accuracy of 99.51% and is two times faster than the two best performing models. In cases where users are restricted to closed-source models due to the unavailability of GPU resources, the OpenAI-3-small model stands out as the most suitable option. Its inference speed is comparable to the OpenAI-Ada model, while it achieves a superior retrieval accuracy.

5 Conclusion and Future Work

In this paper, a novel test dataset was introduced to assess the performance of the RAG system on Slovenian language. A general methodology for efficient creating of non-synthetic RAG test datasets was established that can be extended to other languages. We evaluated the retrieval accuracy of the RAG system, examining the impact of the embedding models, the document chunk size, and the number of retrieved sources. The assessment of embedding models encompassed eight open-source and closed-source LLM models. It revealed that open-source models, specifically, BGE-M3 and mE5-large, reached perfect retrieval accuracy, demonstrating their suitability for RAG applications on Slovenian texts. Furthermore, the evaluation of the optimal chunk size and the number of retrieved sources showed that smaller chunk sizes yielded superior results. In contrast, increasing the number of retrieved sources enhanced results up to a certain threshold, beyond which the model performance plateaued. Certain models already achieved perfect accuracy when evaluated based on the top two retrieved sources.

While the novel test dataset can be used to evaluate all the components of the RAG system, in this paper, we focused on the evaluation of the indexing and retrieval components. In our future work, we will extend the evaluations to the text generation component with regard to fluency, correctness, and usefulness of the generated answers. Furthermore, we plan to expand the benchmark to encompass a wider range of languages. The plans include extending the dataset and evaluation to South Slavic languages and other European languages that are covered by comparable MaCoCu [1] and CLASSLA-web [10] corpora.

Abstract

Feature selection is a crucial step in building effective machine learning models, as it directly impacts model accuracy and interpretability. Driven by the aim of improving stress prediction models, this article evaluates multiple approaches for identifying the most relevant features. The study explores filter-based methods that assess feature importance through correlation analysis, alongside wrapper methods that iteratively optimize feature subsets. Additionally, techniques such as Boruta are analysed for their effectiveness in identifying all important features, while strategies for handling highly correlated variables are also considered. By conducting a comprehensive analysis of these approaches, we assess the role of feature selection in developing stress prediction models.

Keywords

Feature selection, Correlation matrix, Balanced accuracy score

1 Introduction

Machine learning models are increasingly being applied to predict stress, which is critical in various domains such as healthcare, workplace management, and wearable technology. However, one of the major challenges in developing reliable predictive models is identifying the most relevant features from extensive datasets, comprising physiological and behavioural information.

Feature selection plays a key role in addressing this challenge. By selecting only the most informative features, we can reduce noise, prevent overfitting, and enhance model accuracy. As we showed in previous work [8], even simple feature selection techniques can increase the F_1 score of predictive models. This paper builds upon this finding and explores several feature selection techniques, ranging from simple correlation-based methods to more sophisticated wrapper approaches.

The aim of this work is to assess how feature selection can enhance stress prediction models. By comparing different methods, we aim to identify the optimal strategies for feature selection in stress prediction which would lead to more reliable and more easily interpretable machine learning models.

2 Data collection

The data used in this work comes from the STRAW project [1], results of which have been previously presented at Information Society [6, 8]. The dataset includes the data of 56 participants, recruited from academic institutions in Belgium (29 participants) and Slovenia (26 participants). They answered questionnaires named Ecological Momentary Assessments (EMAs) roughly every 90 minutes, with smartphone sensor and usage data continuously collected by an Android application [7], while also wearing an Empatica E4 wristband recording physiological data. In 15 days of their participation, each participant responded to more than 96 EMA sessions, on average, which resulted in around 2200 labels.

3 Target and feature extraction

To fully leverage the potential of the data, we computed a comprehensive set of features. While some sensors only reported relatively rare events, such as phone calls, others had a high sampling frequency, such blood volume pulse which sampled data at 32 Hz. On the other hand, labels were only available every 90 min. Therefore, we preprocessed the data in several steps.

3.1 Target variable

While participants responded to various questionnaires, for this study, we selected their responses to Stress Appraisal Measurement [9] as the target variable. It was used to report stress levels on a scale from 0 to 4, so using it as is the prediction task can be approached as a regression problem.

However, many stress detection studies tend towards a discrete approach, treating stress predominantly as a classification task, often only working with a binary target variable. To convert this into a classification problem, we discretized the target variable into two distinct categories: "no stress", which included all responses with a value of 0, while all others were coded as "stress". With that, we ensured a balanced distribution of the target variable values.

3.2 Features

3.2.1 Data preprocessing. In our work, features were calculated on 30-minute intervals preceding each questionnaire session. From the wide variety of smartphone data and physiological measures, a total of 352 features were extracted and grouped into 22 categories, listed in Table 1. Using physiological data from Empatica wristband, we first calculated specialized physiological features on smaller windows (from 4 s to 120 s, depending on the sensor; see [4] for more details), which were then aggregated over 30 min windows by calculating simple statistical features: mean, median, standard deviation, minimum, and maximum. All of the categorical features were converted into a set of binary features using the one hot encoding technique and the missing values were replaced with the mode.

First, some preliminary data cleaning was performed by excluding one of the feature in pairs exhibiting a correlation coefficient of $|r| \geq 0.95$. Despite this, some of the remaining features still exhibited quite strong correlations as shown in Fig. 1. An interesting observation used in the later stages of feature selection was that high correlation, $|r| \geq 0.8$, was mostly observed

4 Prediction models

4.1 Model performance and validation

To evaluate the performance of the models we used balanced accuracy score which is defined as the average of recall obtained on each class. When adjusted for random chance, it is calculated as

$$\textit{Balanced accuracy} = \frac{TP}{TP+FN} + \frac{TN}{TN+FP} - 1,$$

in the binary case, where TP is the number of true positives, TN is the number of true negatives, FN is the number of false negatives and FP is the number of false positives. This definition is equivalent to Youden's $\mathcal{J}$ [11], which assigns a 0 to a random classifier (indeed, a dummy classifier achieved a score of 0.0208 in our case), while a perfect classifier would achieve a score of 1.

To evaluate the stress detection models described in the following sections, we considered several ways of data partitioning. Since the variations in the results depending on the data split were significant, in order to achieve more consistent accuracy, we employed shuffled 5-fold cross-validation.

We also considered a leave-one-subject-out cross-validation technique. However, this method yielded poor results: using all available features, balanced accuracy was 0.05, while with the 5-fold cross validation it was 0.45. This suggested that the participants were quite different from each other, making it challenging to generalize predictions for a subject the model had not encountered.

4.2 Baseline model

Our initial approach for building a prediction model was to use all available features. This served as a baseline, which we aimed to improve through feature selection.

We evaluated various predictive models, as shown in Table 2, all as implemented in `scikit-learn` [10]. Among these, the Random Forest model yielded the best performance.

In this work, we aimed to find the best model for predicting stress and improve it using the optimal feature subset. Consequently, we used the Random Forest as the benchmark for comparing feature selection algorithms.

Table 2: Performance of different models for the classification problem. The mean over five folds, its standard error, and the maximum are shown.

Model	Mean	Max	SEM
Logistic Regression	0.077	0.151	0.025
Support Vector Machines	0.090	0.158	0.022
Gaussian Naive Bayes	0.061	0.122	0.020
Stochastic Gradient Descent	0.027	0.054	0.007
Random Forest	0.475	0.558	0.026
XGBoost	0.441	0.473	0.013

In Table 2, SEM represents the Standard Error of the Mean. It measures how far the sample mean of the data is likely to be from the true population mean.

4.3 Correlation-Based Feature Reduction

We began the feature selection process by eliminating highly correlated features. For each highly correlated pair, we removed the feature with the lower rank when sorted by mutual information, setting the correlation threshold at $|r| \geq 0.8$ to maintain a manageable number of features. This reduction left us with approximately 180 features out of the original 352 for model training and evaluation.

While selecting the optimal set of features for stress prediction, we aimed to retain all 22 different categories from Table 1, as

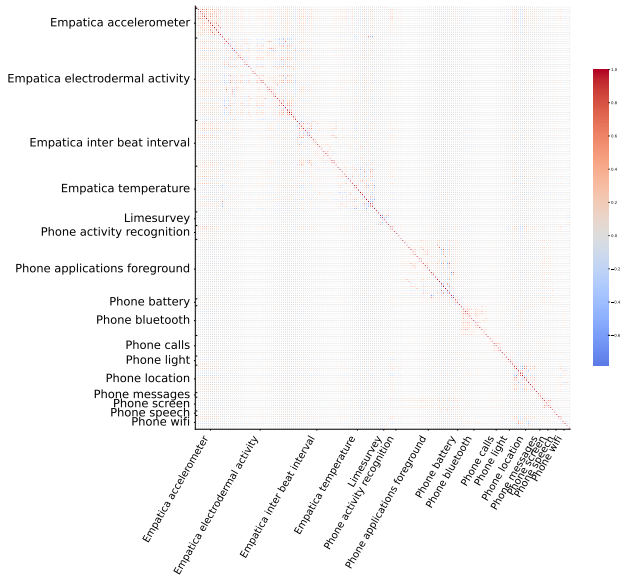

Figure 3: Correlation matrix of the feature set after correlation-based feature reduction. Only feature categories with more than two features are labelled.

each could provide unique information. Comparing Figs. 1 and 3, we were left with about half the number of features which were still moderately correlated.

4.4 Feature Selection using the mutual information scoring function

Before applying more complex feature selection algorithms, it was necessary to reduce computational complexity by further reducing our set of 180 features obtained through correlation-based reduction. Therefore, we used the `SelectKBest` method and the mutual information scoring function to retain the top 100 features. This resulted in features derived from 19 to 20 categories, as categories *language*, *gender*, and, in some cases, *Empatica accelerometer* were not deemed important for predicting stress.

Going forward, we will refer to the elimination of features within highly correlated pairs and the selection of the top 100 features using the mutual information scoring function as the preprocessing step.

4.5 Recursive Feature Elimination with Cross-Validation (RFECV)

One of the previously mentioned complex feature selection methods we employed was Recursive Feature Elimination with Cross-Validation (RFECV) [3]. The feature set we got after the preprocessing step was passed to the RFECV algorithm for thorough evaluation.

RFECV operates by initially fitting a model to the dataset and evaluating its performance through cross-validation. After the initial fit, RFECV ranks feature importance and iteratively removes the least important features based on the models feature importances attributes, which in the case of Random Forest are impurity-based feature importances. This process continues until there is no significant improvement in the model's performance. To ensure a reasonable duration for the feature selection process, we set the cross-validation in RFECV to 3 folds. The number of features selected varied across folds, ranging from 50 to 93 features.

4.6 Sequential Forward Selection

Another feature selection method we employed was Sequential Feature Selector (SFS), a wrapper-based technique [2]. SFS and RFECV differ in their approaches. SFS constructs models for each feature subset at every step, while RFECV builds a single model and evaluates feature importance scores. Consequently, SFS is more computationally expensive, as it must evaluate numerous feature combinations before identifying the optimal subset.

In the absence of specified parameters for number of features to select (`n_features_to_select`) and tolerance (`tol`), the method defaults to selecting half of the available features. The default configuration was used in our analysis, leading the SFS to select the top 50 features.

4.7 Boruta method

The final feature selection technique we employed was the Boruta method [5]. With the assistance of "shadow features", which are original features that have been randomly shuffled, the method identifies a subset of features that are relevant to the classification task at hand. In our case, shadow features were introduced into the feature subset obtained after the preprocessing step.

The updated dataset was trained using the Random Forest model for 100 iterations. In each iteration, all original features ranked higher in importance than the highest-ranked shadow feature were marked as relevant.

Ultimately, a binomial distribution is used to evaluate which features have enough confidence to be kept in the final selection. The number of features selected varied across folds, ranging from 47 to 55 features.

5 Results

In Table 3, the final scores for a Random Forest model built on various feature subsets, as derived from the methods described above, are presented. The data was split using shuffled 5-fold cross-validation, to ensure that the results were not overly dependent on a data split.

Table 3: Adjusted balanced accuracy scores of a Random Forest model, trained on the different feature sets. Last column represents a number of features selected.

Feature set	Mean	Max	SEM	N
All available features	0.464	0.498	0.011	352
Correlation-based reduction	0.483	0.507	0.007	~180
Correlation-based, 100 best	0.486	0.498	0.006	100
Preprocessing, RFECV	0.471	0.511	0.012	50 to 93
Preprocessing, SFS	0.483	0.520	0.017	50
Preprocessing, Boruta	0.481	0.545	0.020	47 to 55
RFECV only	0.465	0.494	0.020	16 to 89
SFS only	0.426	0.468	0.017	30
Boruta only	0.456	0.509	0.015	~75

From Table 3, we can see that the most significant improvement in accuracy came after removing the highly correlated features, with the average adjusted balanced accuracy score rising from 0.46 to 0.48. Best mean accuracy was achieved after the preprocessing step, with only a minor improvement from 0.483 to 0.486.

After eliminating highly correlated features, wrapper methods did not significantly improve the accuracy on average (rows 3 to 6 in Table 3). The Boruta method performed best among the three, with the highest overall maximum accuracy in a single fold. These results led us to investigate whether the wrapper feature selection method alone could manage correlated features without their prior removal and to evaluate the impact of the correlation threshold.

We employed the RFECV, SFS, and Boruta method on the entire feature set of 352 features without applying the preprocessing step. For SFS, only 30 features were selected due to its computational complexity. As shown in the last three rows of Table 3, none of the methods alone were able to improve the result achieved with correlation removal. Highly correlated features were left in the final feature set: for example, we identified three pairs of features with a correlation coefficient exceeding $|r| \geq 0.8$ using SFS alone. Poor results could be attributed either to the importance of the correlation removal step or to the feature subset being too small in the case of the SFS.

5.1 Selecting the best correlation threshold

As previously mentioned, the biggest improvement in score came from removing the feature inside the highly correlated pair. Therefore, we have also experimented with different correlation cut-off values to determine the best threshold.

The highest score was achieved with a correlation threshold of $|r| \geq 0.75$ (Table 4). Considering the impact of cross-validation splits and the relatively minor variance in scores, it appears that our initial threshold of $|r| \geq 0.8$ was also quite effective.

Table 4: Adjusted balanced accuracy scores of a Random Forest model trained on a feature subset excluding features above the correlation threshold. The number of features left after correlation-based feature selection differed over validation folds and its range is shown in the final column.

Threshold	Mean	Max	SEM	N
0.55	0.462	0.506	0.018	28 to 33
0.60	0.467	0.493	0.009	39 to 41
0.65	0.474	0.498	0.008	47 to 50
0.70	0.460	0.501	0.017	61 to 65
0.75	0.498	0.526	0.012	74 to 80
0.80	0.470	0.543	0.022	101 to 107

6 Conclusions

This paper examined different feature selection algorithms to find the most effective subset for stress prediction. The model using the feature subset after correlation removal achieved the highest adjusted balanced accuracy score of 0.483.

Alternative feature selection approaches, including the wrapper methods SFS and RFECV, as well as the Boruta method, applied to the preprocessed feature subset, did not lead to further optimization of the feature subset in terms of model performance. Additionally, applying these methods to the entire set of features did not achieve accuracy levels as high as those obtained after the correlation-based reduction. In the case of SFS, this may be attributed to its selection of only 30 features.

Therefore, our results underscore the critical role of the correlation-based reduction step. In contrast, when this step was omitted wrapper methods alone were unable to effectively perform correlation-based feature reduction. We can therefore conclude that simply relying on feature selection methods, however sophisticated, is not as effective as also considering relationships between features.

It should be noted that the improvements in balanced accuracy are low in all cases. This indicates that results cannot be easily generalized and correlation-based feature selection should not be seen as sufficient in general. Instead, we can speculate that no single feature selection method is the best one and that several should be considered. We should also note that the Pearson correlation coefficient that we used in this work only considers linear relationships between features. Other methods can select features even if they are related in a different way.

Abstract

Predictive modeling in football has emerged as a valuable tool for enhancing decision-making in sports management. This study applies machine learning techniques to predict football match outcomes in the WWIN League of Bosnia and Herzegovina. The aim is to evaluate the effectiveness of various models, including Support Vector Machines (SVM), Logistic Regression, Random Forest, Gradient Boosting, and k-Nearest Neighbors (kNN), in accurately predicting match results based on key features such as shots on target, possession percentage, and home/away status. By (1) gathering and analyzing match data from three seasons, (2) comparing the performance of machine learning models, and (3) drawing conclusions on key performance factors, we demonstrate that SVM achieves the highest accuracy at 83%, outperforming other models. These insights contribute to football management, allowing for data-driven strategic planning and performance optimization. Future research will integrate additional factors such as player injuries and weather conditions to improve the predictive models further.

Keywords

Football match prediction, machine learning, WWIN league, Support Vector Machines, Random Forest

1 Introduction

Accurate predictions of match outcomes can inform a wide range of decisions, from tactical adjustments to player acquisitions, and can improve engagement for fans and stakeholders. While predictive modeling has been extensively applied to top-tier football leagues like the English Premier League, there is limited research on regional leagues such as the WWIN League of Bosnia and Herzegovina. The specificity of the country that is Bosnia and Herzegovina and the WWIN League, which has not been researched in the sphere of sports research, provides context for this step.

The WWIN League of Bosnia and Herzegovina was established in the year 2000 and the same year the WWIN was formed by the merging of three leagues, it became a league covering the entire territory of Bosnia and Herzegovina. Originally, the league consisted of 16 clubs, and, from the 2016-2017 season, the league contains 12 clubs which makes the level of the league higher [25]. The winner is the team that has the most points by the completion of thirty-three rounds; this position will grant a team a place in the UEFA Champions League qualifications [10]; the remaining two teams and the winner of the cup will compete for a place in the UEFA Conference League. Since the founding of the WWIN League of Bosnia and Herzegovina, team with the highest number of titles was HŠK Zrinjski from Mostar who emerged as the winner eight times, followed by Sarajevo which won four times, Zeljeznicar and Borac both won three times, Siroki Brijeg won two times and Leotar and Modrica both won once [12]. Depending on which entity association they belong to, the teams that occupy the last two places in the league at the end of the season are relegated to the league below, with two teams from the First League of the Federation of BiH and the First League of the RS being promoted in their stead. To elevate football in our country to the highest level, we must support in-depth analyses of matches and the factors influencing their outcomes. This will enable coaches to fine-tune strategies for future games, help commentators provide more insightful commentary, and allow fans to develop a deeper understanding and get more pleasure from the match.

The study aims to evaluate the performance of various ML models, including Support Vector Machines (SVM), Logistic Regression, Random Forest, Gradient Boosting, and k-Nearest Neighbors (kNN), in predicting match results. By examining key features such as shots on target, possession percentage, and home/away status, we conduct an analysis based on match data from three seasons of the WWIN League, encompassing 400 matches and key performance metrics.

The remainder of the paper is structured as follows: Section II provides an overview of related work in football ML-based prediction. Section III describes the methodology, including the dataset and models used. Section IV presents the results and analysis of models performance, with a discussion on the practical implications of the findings for football management. Finally, Section V concludes the paper and outlines directions for future research.

2 Literature Review

The prediction of the results of football matches has been recently studied extensively because of its relation to betting and decision-making in sports. Studies examining the employment of ML methods are primarily focused on large European leagues, where extensive and highly detailed data is available. The application of these techniques to regional football leagues, such as the WWIN League of B&H, remains underexplored.

Rodrigues and Pinto [15] used a variety of ML methods, including Naive Bayes, K-nearest neighbors, Random Forest, and SVM, to predict the match outcomes based on previous match data and player attributes. Their studies revealed excellent results in terms of soccer betting profit margins, with the Random Forest approach obtaining a success rate of 65.26% and a profit margin of 26.74%. Rahman [13] dedicated his work to employing deep learning frameworks especially Deep Neural Networks (DNNs) for football match outcome prediction, particularly during FIFA World Cup 2018. The study classified match outcomes

with 63.3% accuracy with DNN architectures with LSTM or GRU cells. Baboota and Kaur [3] used machine learning approaches to predict English Premier League match results. The models compared included Support Vector Machines, Random Forest; and Gradient Boosting. From their study , they ascertained that Gradient Boosting outperformed other models in accuracy and overall predictiveness. Authors in [16] used machine learning techniques, notably SVM and Random Forest Classifier, to predict English Premier League (EPL) football match results. They got 54.3% accuracy with SVM and 49.8% with Random Forest after evaluating data from 2013/2014 to 2018/2019 seasons. Another study [8] employed a few machine learning algorithms to predict matches of the English Premier League season 2017-2018. Models including Linear Regression, SVM, Logistic Regression, Random Forest, and Multinomial Naïve Bayes classier show that the K-nearest neighbors give the best accurate predictions.

In summary, while existing studies have demonstrated the effectiveness of machine learning in football matches prediction, there remains a gap in the application of these techniques to regional leagues like the WWIN League, due to the availability and quality of data. The characteristics of these leagues, such as smaller datasets and potentially different factors influencing match outcomes, require a tailored approach. In lesser-known football leagues models might perform differently due to variations in competitive structures and gameplay strategies, as well. The study of Munđar and Šimić [11] in which they developed a simulation model using the Poisson distribution to predict the seasonal rankings of teams in the Croatian First Football League, highlighted the predictive power of statistical models and demonstrated the significance of home advantage in determining match outcomes, which is also an important factor in the WWIN League.

3 Materials and Methods

In this section, we describe the study conducted, detailing the data collection and feature selection processes, the machine learning models applied, the evaluation metrics used to assess model performance, and the approach taken to analyze key features influencing match outcomes. As a result of providing numerous procedures that are declared in this section, we represent the graphical illustration of our methodology. The steps involved in predicting the outcomes of the WWIN League of Bosnia and Herzegovina, including data collection, preprocessing, model development, and algorithm evaluation.

3.1 Dataset

The authors created the dataset for this study by consolidating information from rezultati.com [14], 1XBET [1], and Sofascore [24]. The unique dataset represents the seasons 2021/2022, 2022/2023, and 2023/2024 of WWIN League of Bosnia and Herzegovina. The platforms provide a wide range of football match data so it is easy to find important information for examination. The dataset includes key match facts as date, day of the week, time, home team, away team, final as well as half-time goals scored in the game, referee details, shots taken at goal as well as corner kicks resulting from these attempts on target, bookings made during play by both teams and other relevant performance indicators.

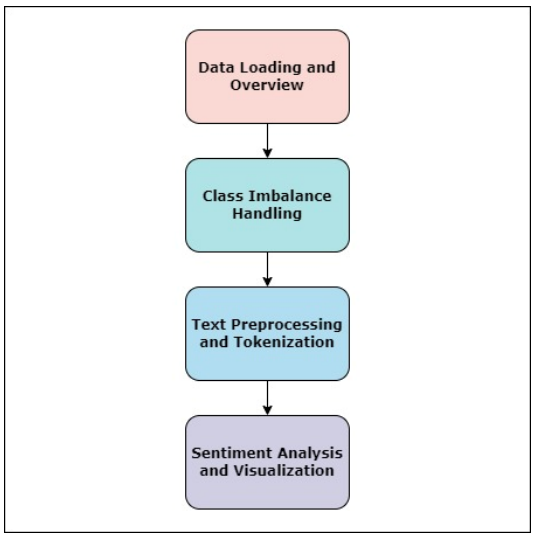

Figure 1: Workflow diagram

Table 1: Class Distribution

Match Type	Count
Home Win	301
Away Win	142
Draw	151

The table sums up a type of match result in terms of its frequency in the dataset.

In the recorded 594 matches, 301 ended in home team victories, 142 in away team victories and 151 were tied. The following pie chart describes the percentage distribution of the match outcome. Curiously, home wins are in the majority, comprising 50.7% of all

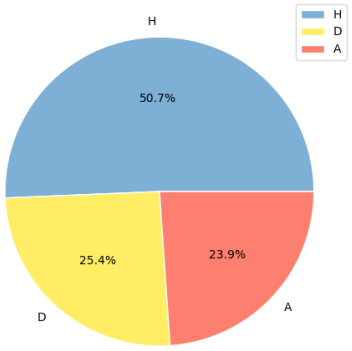

Figure 2: Class distribution of the dataset

matches. However, away victories contribute to approximately 23.9% of all recorded match results, while 25.4% contribute to draw results. The Fig.2 depicts the frequency of each of the match outcomes.

3.2 Machine Learning Prediction

In football, the concept of machine learning prediction entails developing models to forecast match outcomes based on the teams'

and players' histories and other attributes [5]. These models employ such methods as regression analysis, classification, and neural nets to determine the results given the data fed as the input.

3.2.1 Models initialisation, preprocessing, training and testing. While implementing Logistic Regression, we have set the max_iter =1000 and random_state = 42. Again, with the same classifier, the kernel argument was assigned a linear value while the random_state was set to 42 to keep the results predictable. Gaussian Naive Bayes was employed with no modification of its settings because of the model's simplistic nature. For Random Forest, we used the default parameters since the algorithm is capable of changing the setting on its own based on the complexity of given data. We initiated the Gradient Boosting with the default parameters so that the gradients could easily learn and an ensemble could be formed. Last but not least, we left all the parameters of k-Nearest Neighbors (kNN) for default value because the algorithm can find the optimal number of neighbors appropriate for the distribution of the data.

Following that, we proceed with the process of dividing this gathered data into two sets: the training and the testing ones. We split the data into training, where 70% of the data was allocated and the testing data where 30% was allocated.

Subsequently, the phase of model preprocessing is created for which it is essential to filter data effectively to ensure proper model training. In the case of feature transformation, we used scikit-learn's ColumnTransformer [17] to empower the numeric features normalization via the StandardScaler [23] while transforming the categorical variables into the binary format by the use of the OneHotEncoder [18]. This technique pays a lot of attention to ensuring that feature types are standard as well as harmonious. This method ensures consistency by creating a pipeline where preprocessing processes and the model are joined in the same line of work. This means that there is always uniformity in the training and the testing of the model, hence a manageable variability. Assuming the pipeline has been defined and is ready to proceed, we proceed to the next step of model training.

3.2.2 Models in Detail. In this study, many supervised learning classifier techniques that have proven valuable in the sports area for predictive purposes are employed. Logistic Regression is a statistical technique that predicts the probability of a binary classification, using a sigmoid function to map outputs to a [0,1] probability space. Coefficients indicate the strength and direction of relationships between variables, with positive values increasing the likelihood of an event and negative values decreasing it [9].

Random Forest extends the bagging method by generating multiple decision trees using randomly selected data samples. Each tree operates independently, and the final prediction is the average result across all trees, reducing overfitting and improving accuracy in classification tasks [4].

SVM aims to find the best hyperplane to separate data points by class, maximizing the margin between them. It handles nonlinear boundaries by transforming the input data into a higher-dimensional space [2].

Naïve Bayes, based on Bayes' theorem, assumes feature independence, making it fast and easy to implement, especially in applications like spam detection and text classification. Despite the simplicity of this assumption, it performs well in practice [26].

Gradient Boosting combines multiple weak learners (typically decision trees) to create a stronger predictive model, improving accuracy by focusing on correcting errors from previous models [6].

k-Nearest Neighbors (kNN) is an instance-based learning method that classifies data by identifying the majority label among the k closest points. Though simple, it can be computationally expensive as it requires storing all training data and performing real-time comparisons [7].

3.2.3 Evaluation Metrics. Last but not the least, the trained models are assessed by metrics such as accuracy of the models [19], precision of the models [21], the recall of the models [22], and F1-score value of the models [20]. This evaluation enables one to analyze how well each of the models is likely to perform in terms of match outcome prediction.

4 Results and Discussion

In this study, we employed six different classifiers to predict football match outcomes and conducted a comparative analysis of their performance. The effectiveness of each classifier was evaluated based on its accuracy, providing a clear comparison of their predictive capabilities across the dataset.

4.1 Model Performance

Among the classifiers employed, SVM predicted the most accurate results at 83% This model performed almost well, with balanced precision and recall across all three classes (A, D, and H), showing that it can predict match outcomes. In comparison, Random Forest achieved a lower accuracy of 65%, with especially evident deficits in precision and recall for class 'D'. Logistic Regression performed worse than Support Vector Machines, with accuracy of 77%. Despite its simplicity and computational efficiency, Gaussian Naive Bayes had the lowest accuracy of any classifier tested, at 39%. This model struggled to predict class 'D', with low accuracy and recall scores. Random Forest, an established ensemble learning approach, performed not so good, with an accuracy of 54%. This model has generally balanced accuracy and recall across all classes, making it an acceptable alternative for predicting match results. Gradient Boosting, another ensemble learning technique, has a little higher accuracy than Random Forest at 64%. While Gradient Boosting is recognized for its ability to manage complicated connections, it produced poorer recall ratings, especially for class 'D'. Lastly, k-Nearest Neighbors (kNN) resulted in 51% accuracy, showing that the classifier was relatively poor, they had relatively fair precision and recall with all the classes.

For making the match predictions, we employed the following classification models – Logistic Regression, Support Vector Machine, Gaussian Naive Bayes, Random Forest, Gradient Boost and k-Nearest Neighbors. We obtained the results varying from 39% to 83%, in which Support Vector Machines were the most effective. Our findings are partially consistent with prior research because classifiers like Support Vector Machines, Logistic Regression, and Random Forest have manifested robustness in predicting the match outcome across datasets. Nevertheless, the results are not in conformity with some emerging works, particularly concerning the efficacy of Gaussian Naive Bayes, which performed poorly in our study in contrast to other research results. It should be noted that results may vary significantly between different studies depending on the quality, the quantity, and the nature of the data that had been used for creating the models of Gaussian Naive Bayes.

Model	Accuracy	Precision	Recall	F1 score
Logistic Regression	77%	75%	74%	74%
SVM	83%	86%	83%	84%
Gaussian NB	39%	47%	42%	36%
Random Forest	54%	43%	46%	43%
Gradient Boosting	64%	64%	59%	60%
kNN	51%	49%	49%	49%

Table 2: Model Performances

The Table 2 shows how accurate various machine learning models are in predicting WWIN League of Bosnia and Herzegovina match outcomes.

4.1.1 Key factors influencing match outcomes. While this study does not perform formal feature analysis, the observed performance trends allow us to draw conclusions about the key factors influencing match outcomes. In line with prior research, home advantage emerged as a critical factor, with teams winning at home in over 50% of cases (Table 1) which reinforces the psychological and tactical advantages that come with playing on familiar ground.

Offensive metrics, particularly shots on target, also revealed themselves as strong predictors of success. Teams that generated more attempts on goal were significantly more likely to win, reinforcing the widely accepted view that aggressive, forward-driven play translates directly into better results. This trend mirrors observations from other football leagues, where offensive intensity is often directly correlated with victory.

4.1.2 Limitations and future work. Despite the promising results, this study has several limitations. First, the dataset used does not account for external factors such as player injuries, weather conditions, or team morale, all of which can influence match outcomes. Future research should incorporate these factors to improve the accuracy of predictions. Second, while SVM performed well in this context, more advanced models such as deep learning could potentially offer even better predictive performance, particularly when dealing with larger datasets.

Future work will explore the integration of additional domain-specific features, such as player statistics, team form, and environmental conditions, to further refine the predictive models. We will also experiment with more complex algorithms, such as neural networks, to capture the intricate relationships between features that may be missed by traditional machine learning models.

5 Conclusion

This study demonstrates that machine learning, particularly SVM, effectively predicts football match outcomes in the WWIN League of Bosnia and Herzegovina. Support Vector Machine has been found to be the highest accurate classifier with 83% of accuracy rate on match result prediction. SVM has moderate accuracy and recall with all three outcome classes: Home Win, Away Win, and Draw, indicating football prediction applicability. However, it has also revealed that other classifiers' performances are varying with Logistic Regression producing 77% of accuracy and Gaussian Naïve Bayes a poor 39% accuracy. Both Random Forest and Gradient Boosting, which are ensemble learning algorithms, have similar levels of accuracy; 54% and 64% respectively. While further refinement of the models is needed, the current findings establish a strong foundation for data-driven decision-making in football management. Future work should incorporate additional factors such as player injuries and weather conditions to enhance predictive accuracy.

Abstract

The sarcasm detection task in natural language processing tries to classify whether an utterance is sarcastic or not. It is related to sentiment analysis since it often inverts surface sentiment. Because sarcastic sentences are highly dependent on context, and they are often accompanied by various non-verbal cues, the task is challenging. Most of related work focuses on high-resourced languages like English. To build a sarcasm detection dataset for a less-resourced language, such as Slovenian, we leverage two modern techniques: a machine translation specific medium-size transformer model, and a very large generative language model. We explore the viability of translated datasets and how the size of a pretrained transformer affects its ability to detect sarcasm. We train ensembles of detection models and evaluate models' performance. The results show that larger models generally outperform smaller ones and that ensembling can slightly improve sarcasm detection performance. Our best ensemble approach achieves an F_1-score of 0.765 which is close to annotators' agreement in the source language.

Keywords

natural language processing, large language models, sarcasm detection, neural machine translation, BERT model, GPT model, LLaMa model, ensembles

1 Introduction

Sentiment analysis is a popular task in natural language processing (NLP), concerned with the extraction of underlying attitudes and opinions, usually categorized as "positive", "negative", and "neutral". Detection of sentiment is challenging if the utterances are ironic or sarcastic. *Sarcasm* is a form of verbal irony that transforms the surface polarity of an apparently positive or negative utterance/statement into its opposite [6]. Sarcasm is frequent in our day-to-day communication, especially on social media [5]. This poses a significant problem for sentiment analysis tools since sarcasm polarity switches create ambiguity in meaning. Sarcasm is highly dependent on its context. For example, the sentence "*I just love hot weather*" could be interpreted as sarcastic, depending on the situation, e.g., during summer heat waves.

Historical developments of sarcasm detection are surveyed by Joshi et al. [3], while recent developments are covered by Moores and Mago [5]. The problem of automatic sarcasm detection in text is most commonly formulated as a classification task. Unfortunately, sarcasm detection is affected by the lack of large-scale, noise-free datasets. Existing datasets are mostly harvested from microblogging platforms such as Twitter and Reddit, relying on user annotation via distant supervision through hashtags, such as *#sarcasm*, *#sarcastic*, *#not*, etc. This method is popular since 1) only the author of a post can determine whether it is sarcastic or not, and 2) it allows large-scale dataset creation. However, this method introduces large amounts of noise due to lack of context, user errors, and common misuse on social media platforms. The sarcasm detection datasets created through manual annotation tend to be of higher quality but are typically much smaller. These problems are further compounded for non-English datasets, both manually labeled and automatically collected. Further, as sarcasm strongly relies on its context, using classical machine translation (MT) from English often produces inadequate results. This makes sarcasm detection in less-resourced languages, like Slovenian, an even bigger challenge. Therefore, developing reliable sarcasm detection models is of crucial importance for robust sentiment analysis in these languages.

We develop a methodology for sarcasm detection in less-resourced languages and test it on the Slovenian language. We address the problem of missing datasets by comparing state-of-the-art machine translation with large generative models. We explore the viability of such datasets and how the number of parameters affects a model's ability to detect sarcasm. We construct various ensembles of large pretrained language models and evaluate their performance.

The rest of this work is organized as follows. In Section 2, we discuss the proposed approach for detecting sarcasm in a less-resourced language such as Slovenian. We present the creation of a dataset, details of the training methodology and deployed ensemble techniques. We lay out our experimental results and their interpretations in Sections 2.3 and 4. In Section 5, we provide conclusions and directions for future work.

2 Sarcasm Detection Dataset

Existing attempts at automatic sarcasm detection have resulted in the creation of datasets in a small number of languages with differing sizes and quality. It is unclear if models trained on these datasets would generalize well to unseen languages [1]. Since no dataset exists for Slovenian, we leverage recent advances in machine translation and large language models (LLMs) to create a dataset for supervised sarcasm detection. We thus apply a translate-train approach when fine-tuning our models.

The prevalence of research done on sarcasm in English means that English datasets are usually larger and of higher quality than their counterparts in other languages. Further, as the translation from (and to) English is usually of better quality, we consider only English datasets.

Preliminary tests showed poor quality and poor translation ability of `Sarcasm on Reddit`[1] dataset, and `News Headlines Dataset For Sarcasm Detection`[2]. Hence, we chose the recent `iSarcasmEval`[3] dataset from the `SemEval-2022` shared task. We

https://doi.org/10.70314/is.2024.scai.4212

believe that relatively low performance scores obtained in this shared task could be improved with the use of larger LLMs.

2.1 iSarcasmEval Dataset

`iSarcasmEval` is a dataset of both English and Arabic sarcastic and non-sarcastic short-form tweets obtained from Twitter. We use only the English part, which is pre-split into a train and test set. Both sets are unbalanced, the former having 867 sarcastic and 2601 non-sarcastic examples, while the latter has 200 sarcastic and 1200 non-sarcastic examples. The authors of the shared task claim that both distant supervision and manual annotation of datasets produce noisy labels in terms of both false positives and false negatives [1]. Thus, they ask Twitter users to directly provide one sarcastic and three non-sarcastic tweets they have posted in the past. These responses are then filtered to ensure their quality. The produced dataset is not entirely clean since it contains links, emojis, and capitalized text. We chose to leave all of these potential features in the text, as they commonly occur in online conversations and could be indicative of sarcasm.

Let us mention, that an ensemble approach with 15 transformer models and transfer from three external sarcasm datasets proved to be the most accurate modeling technique for English [9] achieving an F_1-score of 0.605.

2.2 Translating iSarcasmEval

Our preliminary testing using smaller BERT-like classifiers showed that the models learned the distribution of the data and defaulted to the majority classifier (1200/1400 = 0.857 test accuracy). To try to dissuade this, we merged the train and test sets, kept all the sarcastic instances, and randomly sampled an equal number of non-sarcastic examples. This left us with a balanced dataset of 2134 samples.

To enable task specific instructions that would preserve sarcasm, we skipped classical machine translation tools, and tried two alternative translation approaches:

- using a medium-sized T5 model trained specifically for neural machine translation,
- leveraging a significantly larger model via OpenAI's API.

The T5 model uses both the encoder and decoder stacks of the Transformer architecture and is trained within a text-to-text framework. We chose Google's 32-layer T5 model called `MADLAD400-10B-MT`[4], which has 10.7 billion parameters and is pretrained on the `MADLAD-400` [4] dataset with 250 billion tokens covering 450 languages. Fine-tuning for machine translation was done on a combination of parallel data sources in 157 languages, including Slovenian.

As a generative model, we chose OpenAI's decoder-based `GPT-4o-2024-05-13`[5]. Its true size is not known to the public, but it's speculated that it is significantly smaller than `GPT-4`, since it is much faster and more efficient. OpenAI claims that it has the best performance across non-English languages of any of their models, thus making it suitable for our task.

When *prompting* generative decoder-based models, it is necessary to craft clear and specific instructions to achieve the best results. We used few-shot learning [2], and randomly sampled three training instances, manually translated them, and included them in the following prompt where the double forward slash was used as a delimiter between the query and the expected response.

You will be provided with a sarcastic/non-sarcastic sentence in English, and your task is to translate it into the Slovenian language. It should keep the original meaning. Examples:

- *love getting assignments at 6:25pm on a Friday!! // obožujem, ko mi v petek ob 18:25 pošljejo naloge!!*
- *I still can't believe England won the World Cup // Še vedno ne morem verjeti, da je Anglija zmagala na svetovnem prvenstvu*
- *taking spanish at ut was not my best decision 😐 // Učenje španščine na UT ni bila moja najboljša odločitev 😐,*

We manually assessed the outputs of both transformers in order to determine the best translations for fine-tuning detection models.

2.3 Translation Results

During translation, the T5 model sometimes had trouble with examples that had multiple newline characters in a row. It occasionally dropped parts of texts it didn't understand (mostly slang and various types of informal text styles). This shows that a 10B parameter model is not large enough to robustly translate all features of a language such as English into a less-resourced language such as Slovenian.

On the other hand, the GPT model performed surprisingly well in most instances and it seemed to have a more nuanced understanding of phrases used in online speech. It consistently translated entire texts, keeping the original structure and meaning. Consequently, we used GPT's translations when training sarcasm detection models. The translations can be seen in our repository[6].

3 Model Training

We tested the performance of a wide range of LLMs of different sizes. Their overview is contained in Table 1.

Table 1: Summary of used sarcasm detection models.

Model	Parameters
`SloBERTa`	110M
`BERT-BASE-MULTILINGUAL-CASED`	179M
`XLM-RoBERTa-BASE`	279M
`XLM-RoBERTa-LARGE`	561M
`META-Llama-3.1-8B-INSTRUCT`	8.03B
`META-Llama-3.1-70B-INSTRUCT`	70.6B
`META-Llama-3.1-405B-INSTRUCT`	406B
`GPT-3.5-TURBO-0125`	?
`GPT-4o-2024-05-13`	?

3.1 Encoder Models Under 1B Parameters

The four smallest models are encoder-based models that embed input text and use a classification head to assign it a class. They required additional fine-tuning to perform sarcasm detection. For these models, we conducted hyperparameter optimization.

We chose the `SloBERTa` [7, 8] model in order to check whether using a monolingual Slovenian model impacts sarcasm detection performance. We also wanted to compare BERT and RoBERTa-like models, so we used their multilingual variants and fine-tuned them on Slovenian data.

The models were trained for a maximum of five epochs with the use of early stopping, where the training was halted if the validation loss didn't improve after two epochs.

[5] platform.openai.com/docs/models/gpt-4o
[6] github.com/GalaxyGHz/Diploma

3.2 Llama 3.1 Models

Since the teams that competed in the 2022 shared task on sarcasm mostly used BERT and RoBERTa models, we extend the testing to include significantly larger models. We chose Meta's open-source Llama family of models, more specifically, their newest Llama 3.1 variants. These come in three different sizes, which was perfect for studying the effects of parameter counts on sarcasm detection. We decided to use the "`instruct`" version of all three models since these were fine-tuned to be better at following instructions.

When prompting LLama and GPT generative models, the following few-shot classification prompt was given, with two positive and two negative examples randomly sampled from our dataset.

You will be provided with text in the Slovenian language, and your task is to classify whether it is sarcastic or not. Use ONLY token 0 (not sarcastic) or 1 (sarcastic) as in the examples:

- *Spanje? Kaj je to... Še nikoli nisem slišal za to? 1*
- *Lepo je biti primerjan z zidom* 😂 *1*
- *To sploh nima smisla. Nehaj kopati. 0*
- *Dne 12. 10. 21 ob 10:30 je bil nivo reke 0,37 m. 0.*

We used full versions of the 8B and 70B parameter models, while the 405B parameter model was loaded in 16-bit precision mode. To minimize the use of resources and costs, we employed LoRA parameter-efficient fine-tuning. We provided the models with training and validation sets and trained them for a maximum of 10 epochs. No hyperparameter optimization was conducted in this case due to time constraints. We used the validation loss to choose the best model, and we used the same early stopping technique as with the smaller models.

3.3 GPT 3 and 4 Models

We also tested two models offered on the OpenAI platform, `GPT-4o-2024-05-13` and `GPT-3.5-TURBO-0125`. We first used them in few-shot mode and classified all our examples without any fine-tuning. When fine-tuning, the platform's tier system limited us to only the smaller `GPT-3.5-TURBO-0125` model. We fine-tuned the model for a maximum of three epochs. In the end, we used the model with the lowest validation loss to classify the examples in the test set.

3.4 Sarcasm Detection Ensembles

When constructing ensemble models, we tried two techniques: stacking and voting. In both cases, we used the predicted probability of the sarcastic class from each model as input features.

3.4.1 Stacking With Regularized Logistic Regression. Our first ensemble used stacking approach, and logistic regression with Ridge regularization as the meta-level classifier. This choice was motivated primarily by the need for feature selection, as we wanted to identify the most important model predictions and determine which models would be assigned a lower weight. The best models were then used for voting.

3.4.2 Standard and Mixed Voting. The second ensembling method was voting. We tried cut-off-based mixed voting inspired by [9]. Formally, we used hard voting when the absolute difference between the number of sarcastic and non-sarcastic predictions was greater than n, and we used soft voting otherwise. We optimized the value of n based on the ensembles performance on our validation set.

When n is set to zero, this approach is equivalent to hard voting, and in the case of n being equal to the predictor count, it is equivalent to soft voting. We report both results. Additionally, we compare the results of voting using all trained models with the results obtained by using only the models with large weights in our regularized logistic regression ensemble.

4 Sarcasm Detection Results

Table 2 summarizes all our results. It is roughly sorted by model size, smaller models being on top and larger ones being on bottom. The `(NFT)` tag indicates that a model was not fine-tuned, while the `(LoRA)` tag means that a model was trained with LoRA. Results are rounded to three decimal places.

Table 2: Summary of performance results for all tested models. The best scores are in bold.

Model	Accuracy	F_1-score
`SloBERTa`	0.621	0.632
`BERT-BASE-MULTILINGUAL-CASED`	0.499	0.666
`XLM-RoBERTa-BASE`	0.578	0.579
`XLM-RoBERTa-LARGE`	0.550	0.597
`Llama-3.1-8B-INSTRUCT (NFT)`	0.560	0.676
`Llama-3.1-8B-INSTRUCT (LoRA)`	0.569	0.682
`Llama-3.1-70B-INSTRUCT (NFT)`	0.660	0.724
`Llama-3.1-70B-INSTRUCT (4-bit-LoRA)`	0.637	0.717
`Llama-3.1-405B-INSTRUCT (16-bit-NFT)`	0.686	0.751
`GPT-3.5-TURBO-0125 (NFT)`	0.564	0.679
`GPT-3.5-TURBO-0125`	0.749	0.760
`GPT-4o-2024-05-13 (NFT)`	0.686	0.746
`L2-LOGISTIC-REGRESSION`	**0.759**	**0.765**
`L2-LOGISTIC-REGRESSION-NON-COMMERCIAL`	0.707	0.749
`HARD-VOTING-ALL`	0.670	0.738
`SOFT-VOTING-ALL`	0.658	0.732
`HARD-VOTING-BEST-5`	0.686	0.749
`SOFT-VOTING-BEST-5`	0.686	0.749

Individual Model Performance

Out of all of the used models, only `BERT-BASE-MULTILINGUAL-CASED` failed to learn any pattern in our data and defaulted to the dummy classifier.

`GPT-3.5-TURBO-0125` sometimes predicts the correct token but then continues to generate additional text, such as 11 and 1\n1. This happens with a small quantity of examples in our testing set. We decided to truncate these responses and only kept the first token as the answer.

The Llama models sometimes refused to generate tokens zero or one. We decided to drop these examples altogether. We report the test accuracy and trained the ensemble models without them.

Smaller encoder models performed poorly when compared to some of the larger models. Only the `SloBERTa` model manages to achieve an accuracy above 0.6. Despite being the smallest of the four small models we tested, `SloBERTa` performed the best. This suggests that the three larger multilingual encoder models may lack sufficient understanding of Slovenian. It also highlights that model size alone does not necessarily correlate with better performance when it comes to sarcasm detection.

The Llama models fared better, achieving accuracies of up to 0.686 with the 405B model being comparable to GPT-4o in performance. They still fell short of the fine-tuned `GPT-3.5-TURBO-0125` model, which managed to successfully classify about three-quarters of our examples with a F_1-score of 0.76.

Some models had significantly higher F_1-scores and lower accuracies. We show the confusion matrix of one of the models

Table 3: Confusion Matrix for non-fine-tuned `Llama-3.1-405B-INSTRUCT` model.

Predicted \ Actual	Positive	Negative
Positive	202	123
Negative	11	91

that exhibited the largest difference in Table 3. These models seem to have a tendency to incorrectly classify non-sarcastic text as sarcastic, leading to a high rate of false positives.

Our testing also showed that loading the `Llama-3.1-70B--INSTRUCT` model in 4-bit mode and fine-tuning it with LoRA does not produce satisfactory results, and it is thus better to conduct full fine-tuning with the smaller Llama model or to use one of OpenAI's models via their fine-tuning API.

`GPT-3.5-TURBO-0125` performed the best among individual models, so if costs associated with the use of OpenAI's API are acceptable, we recommend its use for sarcasm detection in Slovenian. This shows that very large models can effectively identify sarcasm. We believe that with better parameter tuning, Llama 8B could be one of the best (and most economical) options for sarcasm detection in Slovenian, provided that the user has sufficient hardware resources.

Ensemble Model Performance

We observed that the regularized logistic regression mostly relied on the best-performing models. Its focus on the best model (`GPT-3.5-TURBO-0125`), however, suggests that there is significant overlap between the various model predictions.

We decided to discard `BERT-BASE-MULTILINGUAL-CASED` when constructing our voting ensembles since its dummy classification didn't contribute to overall model performance. Both of these two voting classifiers had an odd number of predictors, so there was no need for a tie-breaker mechanism.

Voting proved to be ineffective in our setups, even scoring lower than some of its base models. hard voting generally outperformed soft voting. We also note that there was no benefit in using mixed voting, at least for the sets of predictors that we obtained as hard voting always had a higher accuracy. This was true for both the classifiers that used all and only five of the base models.

Regularized logistic regression managed to improve on the scores of individual models, raising accuracy by one percent, thus achieving the best performance out of all of the tested approaches. This shows that there is still performance to be gained from ensembles; however, it is still necessary to use commercial models for top performance.

5 Conclusion

In this work, we presented the task of sarcasm detection in the less-resourced Slovenian language. Our code and results are freely available[7].

We tackled the missing dataset problem by using two LLMs to perform neural translation of an English dataset into Slovenian. The translations generated by `GPT-4o-2024-05-13` outpaced those generated by a large T5 model specifically trained for neural machine translation in terms of quality.

We used this data to train a plethora of Transformer-based models in various settings. We found that fine-tuning `GPT-3.5--TURBO-0125` via OpenAI's API results in the highest individual Slovenian sarcasm detection power, but we also note that a possible alternative could be local fine-tuning of the `Llama-3.1-8B--INSTRUCT` model. Our testing shows that using aggressive quantization combined with LoRA results in significant performance degradation.

We also constructed ensemble models based on voting and stacking methods. Observations showed that voting didn't result in any performance improvements. On the other hand, stacking with the use of a regularized logistic regression managed to improve on the performance of its base models.

Additional work needs to be done in dataset construction. Sarcastic examples could be extended with context or labels of the types of sarcasm they represent. This might help guide models towards better understanding of sarcasm. Future work could also explore incorporating heterogeneous models into ensembles or the creation of Mixture of Experts (MoE) ensembles, whose baseline models would focus on different aspects of sarcasm.

Abstract

Digital tracking of services is one of the main administrative burdens of the healthcare staff. Here, we present a proof-of-concept study of a so-called speech-to-service (S2S) system that is aimed at facilitating recording of activities, extracting information from the conversation between a healthcare provider and recipient. The system comprises of a speech recorder, a diarization component, an LLM to interpret the conversation, and a recommendation system integrated in a smart tablet that records completed activities and suggests possible other activities that may have still be required. We tested the system on 350 conversations and obtained 95% accuracy, 97% precision and 94% recall.

Keywords

healthcare, LLM, speech recognition, recommendation system

1 Introduction

Healthcare workers, including nurses, technicians, and care personnel form the backbone of the health system as they care for patients and tend to their needs. However, with the standardization and systematization of the healthcare professions and services often becomes a large bureaucratic burden, as healthcare workers have to record all the activities and services they provide to the patients. This process is of course needed as it provides traceability and ensures that all the required activities were taken care of, but the problem is that the interfaces designed for activity logging are often not user-friendly and require the users to choose the activities from a extensive lists of drop-down menus. In total, this amounts to substantial time required only for tedious administrative tasks, time that would be more beneficially spent otherwise.

With the aim to alleviate the administrative burden of activity logging, we explored the possibilities of novel technologies to assist the healthcare staff in their logging tasks. We developed and tested a proof-of-concept system that records the conversation between the healthcare worker and a patient, identifies the activities, and allows the healthcare worker to batch-confirm them on a dedicated smart tablet. Batch-confirmation saves a lot of time by significantly lowering the number of clicks required in the UI. The system is built using open-source or publicly accessible components, particularly a speech-to-text system that transcribes the recorded conversation, and a large language model (LLM) that leverages its natural language processing capabilities. The recommender system shows possible required tasks, serving as a reminder and to suggest tasks that are expected soon, which may lower the number of visits per patient. These recommended tasks are then suggested to the healthcare worker, who can review and confirm them using the LLM-assisted interface. LLMs, such as ChatGPT and Llama, have seen a surge in popularity in a wide variety of topics since their popularization in particular with the unveiling of ChatGPT3 in the autumn of 2022.

Several LLM based systems have been proposed recently, including administrative task automation [6], decision making process [10], improving existing automatic speech recognition (ASR) systems [1], and providing patients with needed information [9]. A recent study [11] concludes that utilising ASR to ease some administrative tasks leads to faster, more efficient work and even increase workers' moods.

2 System Architecture

This paper describes two early prototype systems, both aiming to alleviate the workload of healthcare workers by easing the task of documenting care actions performed. These are the ASR system that logs care actions based on captured dialogue between the healthcare worker and the patient, and a recommender system that predicts the required services at a specific time. This recommender system relies on the historical data, appropriate for long-term patient care facilities.

Both systems are limited in scope and only target the most common healthcare services in the dataset for detection or prediction respectively, which can still greatly easy the workload for medical workers, since the top 10 most common tasks out of around 200 care action types represent around 80% of all services performed.

The recommender system allows the care workers to anticipate tasks in advance and server as a reminder. This aims to lower the number of patient visits, which also alleviates the workload.

2.1 Speech-to-Service ASR

The ASR system consists of a speech diarization model, capable of segmenting the recorded speech based on who is currently speaking, a speech transcription model that transcribes the audio

to text, and a LLM fine-tuned to extract specific information from the text. Figure 1 shows the architecture of the prototype system.

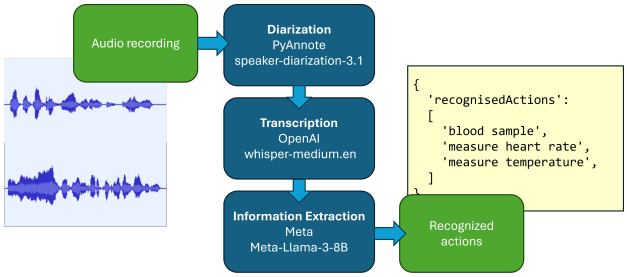

Figure 1: Overview of the ASR system.

We employ speaker-diarization pretrained model [1][4] for diarization, pyannote/speaker-diarization-3.1 pretrained model [7] for transcription, and fine-tuned Llama3 model[2][2] for information extraction via generating JSON formatted output.

2.2 Recommender System

The recommender system prototype is based on machine-learning prediction of events that are expected to occur in a certain time window for a specific patient with addition of tasks that commonly follow predicted tasks. Due to the sensitive nature of the data, we base our predictions only on the time window, patient ID and care type. Thus we consider multi-output binary classifiers that do not require large amounts of data for training. Additional tasks are added to the list based on a Markov chain model that commonly follow, e.g. the task 'clean table' follows the task 'lunch'.

The feature vector includes the time of day, day of week, week of month and month of year as numbers, allowing for capture of periodic events with different periods. Due to lack of patient data, we opted for personalized models, trained for each patient separately. We believe that results can be further improved by adding more patient-related attributes. The model training used five month period of data collected, with cross-validation, and the accuracy was evaluated on the data collected during the sixth month. Due to patients' medical states changing over time, some data drift is expected, which is reflected in our results.

3 Dataset

To fine-tune the information extraction model based on Llama3, we have created a dataset of conversations in text form and appropriate outputs for each of them, as the task on hand is very specific and we did not find any existing appropriate dataset. We automated the process and manually removed any bad examples. A real dataset, ideally recorded in the target environment, is needed for for final implementation - LLM generated datasets used for training LLMs are only appropriate in preliminary studies.

To generate the dataset, we prepared a BERT [3] LLM via prompting [5]. A training sample was generating by first randomly selecting 2 of the 10 target actions, and programmatically generating the target output JSON. The BERT model was then tasked with generating a conversation, in which these two tasks are mentioned as done during the conversation. We generated several hundred conversations that way, and manually checked for mistakes in the model output. Many conversations were removed due to selected actions not being mentioned or other reasons. Finally, the resulting dataset contains 350 conversations and JSON formatted lists of tasks.

For the prediction of services required during a visit, we have acquired a log of all services performed in one long-term patient care facility over a period of 6 months, with the next version expanding to data from six facilities. The tasks in dataset include measurements (body temperature, heart rate, blood pressure, ...), medical tasks (monitoring medicine intake, performing examinations, turning the patient in bed) and care tasks (breakfast, lunch, cleaning). There are over 200 different tasks mentioned. The dataset includes limited patient information—patient ID, care type, and a detailed chronological history of services received. Care types (CareType I, CareType II, CareType III/A, CareType III/B, CareType IIII) represent an estimate of how much assistance a person requires. Legal restrictions on accessing sensitive health data prevented us from obtaining more detailed patient records, so we developed prediction models based on these limited data points, balancing accuracy with regulatory constraints.

The data preprocessing involved determining each patient's presence in the facility by identifying the timestamps of their first and last recorded service. Patients with a stay of less than four months were excluded from the analysis to ensure sufficient data for reliable predictions.

4 Methods

This section describes the methodology used to develop the ASR system and the recommender system.

4.1 Clustering

The primary goal of the clustering process was to group patients with similar patterns in terms of the type and frequency of services they received, allowing us to predict relevant services more effectively for each cluster (since it was not clear, even among experts, whether care type and actual care provided were correlated).

The clusters, as shown in Figure 2, demonstrate that patients within the same care type tend to receive similar services. Some deviations, where multiple classifications appear within a cluster, are likely due to temporary conditions we could not fully exclude (for instance, an individual categorized under "Care Type II" may temporarily receive services typical of "Care Type III/A" (e.g. due to a broken arm), while their care type classification remains unchanged). Despite this, the care types differentiate well enough across clusters, leading us to use "CareType" as one of the key attribute for further service predictions.

In the clustering process, we excluded CareType IIII because this group is characterized by highly diverse healthcare needs due to specific diseases, and experts advised us to omit it for this part of the analysis.

4.2 Recommender System

To recommend the required services, we constructed the training dataset using a detailed log of care actions performed over a 6-month period. For each patient, the data was divided into consecutive 4-hour time windows. In each window, we examined whether specific care actions were performed, marking them as "positive" if they occurred within that time frame. This granular approach allowed us to capture the temporal dynamics of

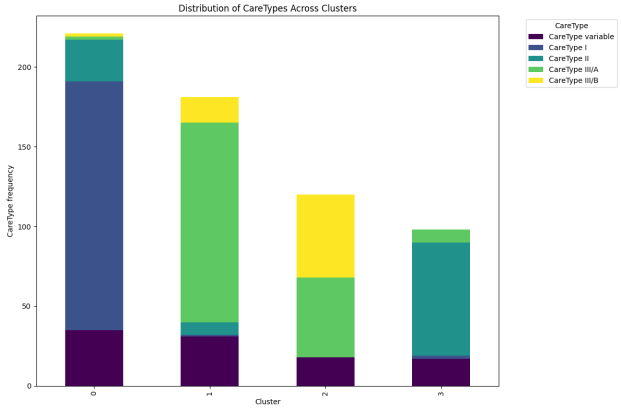

Figure 2: Clustering of patients closely aligns with pre-existing care type assignments, ranging from minimal personal assistance (CareType I) to moderate assistance (CareType II), and full or intensive personal assistance (CareTypes III/A and III/B) for those with more severe care needs.

service delivery, ensuring that for each time window, we had a clear record of the services provided. As a result, we generated over 1000 labeled examples per patient, with each example representing a specific time window and its associated care actions. This enabled the model to learn patterns in service requirements throughout the day and week.

To identify the best predictive model, we evaluated various classification algorithms, including Random Forest, Decision Tree, K-Neighbors, Support Vector Classifier (SVC), Gradient Boosting, and Naive Bayes. Each model was trained using a multi-output classification approach, with features including the frequency of the top services provided and the relevant time attributes. To ensure robust model evaluation, we implemented 5-fold cross-validation and subsequently tested the models on the sixth month's data to assess their predictive performance.

4.3 Speech Recognition and Information Extraction

Due to limited availability of training data, only the information-extraction model based on Llama3 was fine tuned using few-shot LoRA (low-rank adaptor) supervised training. The diarization and transcription models are used unchanged.

The diarization model used is speaker-diarization [4]. Initial experiments with few-shot LoRA fine tuning [3] did not improve the performance, hinting at the need for a larger training dataset. The model's performance is satisfactory at the task of segmentation, but less so at the task of identifying which segments belong to which speaker, especially for longer conversations. For a two-speaker situation, the model seems to assume the speakers take turns speaking, causing mistakes when a single speaker pauses before continuing to speak.

The transcription model used is whisper [8]. The model transcribes each segment separately. As mentioned above, the speakers are not robustly recognised, and we cannot reliably assign a speaker to each line of text. Still, labeling each line of text even with an ambiguous label improves the downstream task of information extraction. The transcribed lines of text are concatenated, and at the start of each utterance a label marking it as such is added. Thus, the transcribed text resembles a play with unknown characters speaking.

The information extraction model is Llama3 [2], and fine-tuned utilising a LoRA few-shot fine tuning. Our approach was to fine-tune the model for the task of extracting information about specific care actions and generate the output in a JSON format, providing structured data directly. A small training dataset was prepared as described in the section 3.

5 Results and Discussion

5.1 LLM Based Infromation Retrieval Model

The Llama3 based information extraction model is evaluated using a 5-fold cross validation, achieving **95% accuracy**, **97% precision**, and **94% recall**. For evaluation the model's JSON-formatted strings were deserialized to objects and tested against known correct objects to be able to interpret the results as multi-label binary classification.

The LLM infromation extraction model sometimes generates invalid JSON after fine-tuning, most commonly due to duplicated keys or getting stuck in a loop, generating same elements until maximum output size is generated. The generated strings are therefore post-processed to fix these mistakes via simple string manipulation, however this indicates that experiments with different output formats or avoiding generating the answers should be performed.

The whole ASR pipeline including diarization and transcription has not yet been evaluated and falls within the scope of future work.

5.2 Recommender System

Tables 1 and 3 present the classification results. Table 1 reports the average performance across all patients, including standard deviations for the different models, while Table 3 shows classification accuracy by care type, with averages and standard deviations across all patients within each care type, based on the model with the best results, which in this case is K-Neighbors (KNN).

Results are reported in two ways, tables 1 and 3 show accuracy considering all target attributes, only considering a prediction correct when all targets are predicted correctly. The table 2 show average of accuracies for each target attribute.

Table 1: Cross-validation and test accuracy (mean ± standard deviation) across all patients for various classification models.

Model	CV Accuracy	Test Accuracy
RandomForest	0.71 ± 0.14	0.66 ± 0.16
DecisionTree	0.65 ± 0.16	0.66 ± 0.16
KNeighbors	**0.73 ± 0.13**	**0.71 ± 0.16**
SVC	0.63 ± 0.12	0.63 ± 0.14
GradientBoosting	0.68 ± 0.12	0.66 ± 0.15
NaiveBayes	0.57 ± 0.17	0.55 ± 0.20

The K-Neighbors (KNN) classifier outperformed other models, achieving an average CV accuracy of 73%, a test accuracy of 71%, and R^2 score of 0.44. This made it the most effective model for predicting service plans. Random Forest also performed reasonably well, achieving a test accuracy of 66%, though it did not surpass KNN in overall performance.

Table 2: Majority Class Percentage and Task-wise Test Accuracy (mean ± standard deviation) across all patients for various classification models.

Model	Majority Class Percentage	Task-wise Accuracy
RandomForest	0.72 ± 0.19	0.89 ± 0.10
DecisionTree	0.72 ± 0.19	0.89 ± 0.11
KNeighbors	**0.72 ± 0.19**	**0.91 ± 0.10**
SVC	0.65 ± 0.16	0.88 ± 0.10
GradientBoosting	0.65 ± 0.16	0.89 ± 0.09
NaiveBayes	0.72 ± 0.19	0.85 ± 0.15

Table 3: Classification performance of K-Neighbors (KNN) by CareType, showing cross-validation and test accuracy (mean ± standard deviation), averaged across all patients within each care type.

CareType	CV Accuracy	Test Accuracy
CareType I	0.79 ± 0.12	0.76 ± 0.16
CareType II	0.79 ± 0.11	0.78 ± 0.13
CareType III/A	0.68 ± 0.13	0.66 ± 0.15
CareType III/B	0.70 ± 0.14	0.68 ± 0.17
CareType IIII	0.68 ± 0.10	0.67 ± 0.12

Since all predictive accuracy values exceed the 70% majority class baseline, this is an excellent result. In multi-label classification, where multiple services are predicted simultaneously, it's important to not only focus on overall accuracy but also on the accuracy of each individual task. By achieving 90% accuracy on the most common tasks, the model ensures that key services are reliably predicted.

The lower test accuracy compared to cross-validation can be explained by temporal changes in patient conditions, as the test set only included the last month of data. As patient care needs shift over time, predicting long-term patterns is more challenging than shorter-term cross-validation, where care remains more stable.

The test accuracy also reflected noticeable differences across care types. CareType I and CareType II showed higher accuracy rates, while more complex types, such as CareType III/A, III/B, and IIII, exhibited a drop in accuracy of around 10%. This is likely due to the more diverse and unpredictable care needs in these groups, making service prediction more challenging.

This approach, particularly with the strong performance of our K-Neighbors (KNN) model, demonstrated the potential of machine learning to enhance personalized planning in healthcare. In future work, including additional patient-specific features beyond time-based data, such as health-related attributes, could further improve accuracy, particularly for the more complex care types.

6 Conclusions

This is early work and further improvements are underway. The whole ASR pipeline needs to be evaluated and we expect noticeably worse performance comparing to only the information extraction model due to larger complexity and possibility for failure at each step. The information retrieval model itself is not inefficient considering computational time and memory required, but diarization and transcription steps are. The required service prediction should also be further improved. Using current dataset an alternative approach that may improve performance is using sequence modelling or event prediction approaches. Finally, the two models could work in tandem - predicting the required actions and using that information in the ASR pipeline could be beneficial.

Based on the proof-of-concept study, we conclude the suggested approach is in principle feasible and can be beneficial to healthcare providers. However, in view of regulations, special caution has to be paid during the implementation of any sort of such system in a real-world setting. Recording and diarizing conversations between healthcare staff and the patients is likely to include highly personal data, which falls under the EU relevant legislation, specifically the GDPR (*General Data Protection Regulation*) [4] and the EU AI Act (*Artificial Intelligence Act (Regulation (EU) 2024/1689)*) [5]. Furthermore, indiscriminately recording conversations and feeding them into an LLM will likely be considered as "high risk" in view of the AI Act. This means that implementing such services will require extensive screening, documentation, clear division of ownership and access roles, and other compliance with legal requirements.

Acknowledgements

We thank the healthcare provider organization for the dataset and for insightful discussions.

Abstract

Accurate vehicle axle weight estimation is essential for the maintenance and safety of transportation infrastructure. This study evaluates and compares the performance of various algorithms for axle weight prediction using time-series data. The algorithms assessed include traditional machine learning models (e.g., random forest) and advanced deep learning techniques (e.g., convolutional neural networks). The evaluation utilized datasets comprising time-series data from 10 sensors positioned on a single lane of a bridge, with the goal of predicting each vehicle's axle weights based on the signals from these sensors. Each algorithm's performance was measured against the OIML R-134 recommendation, where a prediction was classified as accurate if the error was within ±4 percent for two-axle vehicles and ±8 percent for vehicles with more than two axles. Tests were conducted on several bridges, with this paper presenting detailed results from the Lopata bridge. Findings indicate that deep learning models, particularly convolutional neural networks, significantly outperform traditional methods in terms of accuracy and their ability to adapt to complex patterns in time-series data. This study provides a valuable reference for researchers and practitioners aiming to enhance axle weight prediction systems, thereby contributing to more effective infrastructure management and safety monitoring.

Keywords

time-series data, axle weight, machine learning, neural network

1 Introduction

Accurate axle weight prediction plays a pivotal role in the maintenance and safety of transportation infrastructure [7]. The precise estimation of axle weights is essential for various applications, including road maintenance planning, traffic management, and the prevention of overloading, which can lead to premature road wear and increased accident risks [8]. Traditional methods for axle weight measurement often rely on static scales or weigh-in-motion (WIM) systems. While these methods provide direct measurements, they are susceptible to limitations such as high installation and maintenance costs, potential measurement inaccuracies due to environmental factors, and the need for frequent calibration.

In recent years, the advent of advanced computational techniques has opened new avenues for improving axle weight prediction. Machine learning (ML) and deep learning (DL) algorithms, in particular, offer promising alternatives by leveraging time-series data to model complex, non-linear relationships inherent in vehicular weight patterns. These methods can enhance prediction accuracy, handle large volumes of data, and adapt to varying conditions, making them suitable for real-world applications where traditional methods may fall short.

This study systematically evaluates and compares the performance of various axle weight prediction algorithms using time-series data. We focus on a diverse set of algorithms, including machine learning models like random forests (RF) [6] and advanced deep learning techniques such as convolutional neural networks (CNN) [4].

The objective of this research is to explore the potential of combining traditional WIM systems with advanced ML and DL models to enhance axle weight predictions. By comparing the performance of different methodologies, including the SIWIM traditional model, random forest (IJS RF), a hybrid approach (AVERAGE(IJS, SIWIM traditional)), and a CNN-based model, this study aims to identify the most effective strategies for accurate and reliable axle weight estimation. Additionally, it examines the impact of synthetic data generation on the performance of these models, providing a comprehensive evaluation of their practical applicability in real-world scenarios.

The study aimed to predict the axle weights of vehicles using ten input signals from sensors placed under the Lopata bridge.

Each predictive algorithm's performance was evaluated according to the OIML R-134 recommendation, which is deemed accurate if the error margin for predicting the axle weight is within ±4% for vehicles with two axles and within ±8% for vehicles with more than two axles.

The dataset comprised 1478 samples, i.e. passing of a vehicle, each containing 10 signals per vehicle. For each sample, a static weight for each axle was assigned as the target value. Static weight refers to the weight measured by a scale when the vehicle is stationary.

This paper is structured as follows: Section 2 reviews several state-of-the-art approaches. Section 3 details the preprocessing steps necessary before applying machine learning methods. In Section 4, algorithms used for predicting axle weights are presented. Section 5 presents the final results of the axle weight predictions. Finally, Section 6 summarizes the findings and proposes ideas for future research.

2 Related Work

The prediction of axle weights using time-series data has often been studied in recent years, resulting in a substantial body of related work. Below, several state-of-the-art (SOTA) approaches are described.

Zhou et al. [10] differentiated between high-speed and low-speed weigh-in-motion (WIM) systems and analyzed the characteristics of axle weight signals. They proposed a nonlinear curve-fitting algorithm, detailing its implementation. Numerical simulations and field experiments assessed the method's performance, demonstrating its effectiveness with maximum weighing errors for the front axle, rear axle, and gross weights recorded at 4.01%, 5.24%, and 3.92%, respectively, at speeds of 15 km/h or lower.

Wu et al. [8] introduced a modified encoder-decoder architecture with a signal-reconstruction layer to identify vehicle properties (velocity, wheelbase, axle weight) using the bridge's dynamic response. This unsupervised encoder-decoder method extracts higher features from the original data. A numerical bridge model based on vehicle-bridge coupling vibration theory demonstrated the method's applicability. Results indicated that the proposed approach accurately predicts traffic loads without additional sensors or vehicle weight labels, achieving better stability and reliability even with significant data pollution.

Xu et al. [9] applied wavelet transform for denoising and reconstructing the WIM signal, and used a back propagation (BP) neural network optimized by the brain storm optimization (BSO) algorithm to process the WIM signal. Comparing the predictive abilities of BP neural networks optimized by different algorithms, they found the BSO-BP WIM model to exhibit fast convergence and high accuracy, with a maximum gross weight relative error of 1.41% and a maximum axle weight relative error of 6.69%.

Kim et al. [5] developed signal analysis algorithms using artificial neural networks (ANN) for Bridge Weigh-in-Motion (B-WIM) systems. Their procedure involved extracting information on vehicle weight, speed, and axle count from time-domain strain data. ANNs were selected for their effectiveness in incorporating dynamic effects and bridge-vehicle interactions. Vehicle experiments with various load cases were conducted on two bridge types: a simply supported pre-stressed concrete girder bridge and a cable-stayed bridge. High-speed and low-speed WIM systems were used to cross-check and validate the algorithms' performance.

Bosso et al. [1] proposed a method using weigh-in-motion (WIM) data and regression trees to identify patterns in overloaded truck weights and travel. The analysis reveals that truck type is the key predictor of overloading, while time of day is crucial for axle overloading, with most incidents occurring late at night or early morning. These insights can enhance enforcement strategies and inform pavement management and design, optimizing infrastructure longevity and safety.

He et al. [2] introduced a new method that uses only the flexural strain signals from weighing sensors to identify axle spacing and weights, reducing installation costs and expanding BWIM applications. The method's accuracy is validated through numerical simulations and laboratory experiments with a scaled vehicle-bridge interaction model, showing promising results for accurate axle spacing and weight identification.

3 Data Preprocessing

Before applying various algorithms to the dataset, several preprocessing steps were necessary. Due to the differing lengths of signals from each sample, padding was performed to standardize them to the length of the longest signal. Samples with a gross weight below 5 kN were excluded from both the training and test datasets. Each signal was cropped by removing data to the left of the leftmost peak value minus 100 and to the right of the rightmost peak value plus 100. The peak values were calculated in advance.

To address the limited availability of data required for deep learning, which typically necessitates tens of thousands of samples for effective training, synthetic data generation was employed. The original dataset comprised 1,478 samples (from January 2022 to December 2023) i.e. passing of a vehicle, each containing 10 signals per vehicle. An additional 20,000 synthetic samples were generated using a specific algorithm. This algorithm operates by iterating 20,000 times, during each of which a random training sample and a random strain factor were selected. The strain factor is a random value ranging between 0.5 and 0.99. The selected signal from the training sample was then scaled by the chosen strain factor. This scaling process effectively models the feature that doubling the amplitude of the signal corresponds to doubling its weight.

A crucial aspect of data preprocessing involved the normalization of sensor signals to ensure uniformity across the dataset. Each signal was normalized to have a mean of zero and a standard deviation of one, which helps in improving the convergence of machine learning algorithms by ensuring that each feature contributes equally to the learning process.

The selection of training and test data was conducted using a rolling window approach [3]. Specifically, for each testing month, the training data comprised all available data up to but not including the testing month. For instance, if May 2023 was designated as the testing month, the training dataset consisted of data from January 2022 through April 2023. This process was systematically repeated for each testing month from March 2022 to December 2023.

4 Methodology

Four methods were identified as applicable for predicting vehicle axle weights. The first method, known as SIWIM traditional [11], calculated the number of axles, axle lengths, and axle weights by utilizing influence lines to model the signal and determine the correct output. For validation purposes, each predicted output

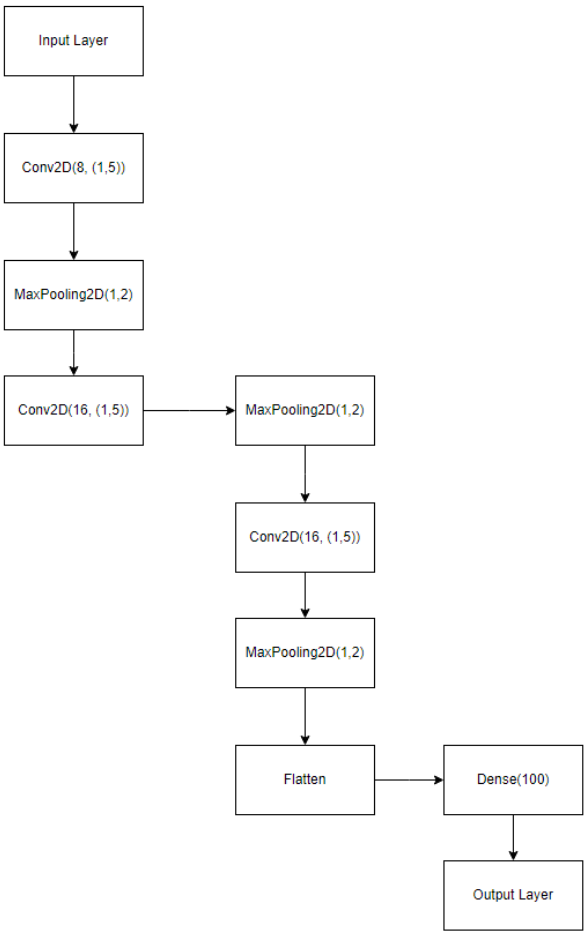

Figure 1: Architecture of CNN for predicting axle weights.

was stored in a separate file alongside the signal data, enabling direct comparison with the actual values.

The second method used the random forest [6] (named IJS RF) for predicting vehicle axle weights. The model relied on accurately identifying the positions of peaks to function correctly. Peak values were determined using the *find_peaks* method from the SciPy library, which identifies peaks based on a specified minimum height. Once the peaks were identified, the algorithm extracted values within a ±5 range of each peak. These extracted values were then used as input features for the random forest model. Additionally, the random forest model incorporated temperature, axle distances and gross weight as input features. Random forest algorithms are not inherently suited for time series data; however, they perform effectively with numerical data such as temperature, axle distance, and gross weight. Therefore, this algorithm was chosen for analyzing this type of input data.

The third method integrated the first two approaches by averaging the outputs from the SIWIM traditional and IJS RF models (named AVERAGE(IJS, SIWIM traditional)). This approach is motivated by the concept that combining multiple models can often yield more accurate results than relying on a single model alone [12].

The final method employed a convolutional neural network (CNN) to predict axle weights. The CNN utilized synthetic data, as detailed in section 3, during the training phase. This method processed all 10 signals as input to calculate the axle weights. The detailed architecture of the CNN is shown in Figure 1. 2D Convolutional layers (Conv2D) were used instead of 1D Convolutional layers due to the input data consisting of 10 sensor signals. The number of filters and kernel size are specified within the parentheses of each Conv2D layer, while the pooling size is defined in each 2D MaxPooling layer parentheses (MaxPooling2D). The last Dense layer has 100 neurons. To mitigate overfitting, a Dropout layer was added after the final Dense layer. Additionally, Batch Normalization was applied after each 2D Convolutional layer to further reduce the risk of overfitting.

Although Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU) neural networks could be used for this task, a Convolutional Neural Network (CNN) was chosen instead because of its strengths in capturing spatial hierarchies and local patterns within the data. CNNs are highly effective at extracting local features and detecting patterns, while LSTM and GRU are better suited for handling temporal dependencies, which are not that relevant to this specific task.

5 Results

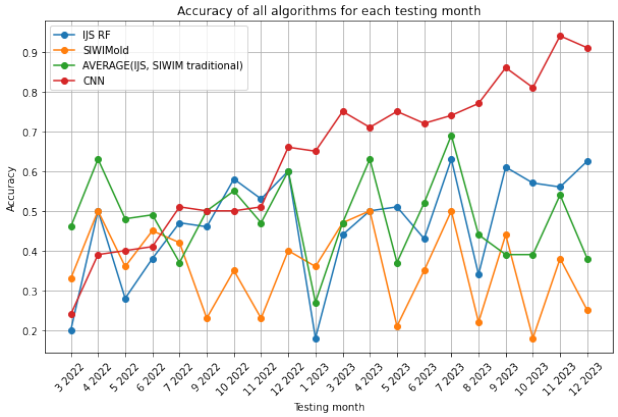

Figure 2: Accuracies of all algorithms for each testing month.

The results of each method described in Section 4 are illustrated in Figure 2. Among the methods evaluated, SIWIM traditional exhibited the poorest performance, with fluctuating trends observed throughout the entire two-year period. The CNN began to outperform the other three approaches after December 2022. Conversely, the AVERAGE(IJS, SIWIM traditional) method showed superior performance during the initial testing months from March 2022 to June 2022.

The performance of the CNN improved with an increasing amount of data, whereas the IJS RF and AVERAGE(IJS, SIWIM traditional) methods were more effective during the initial phase when less training data was available. However, the improvement in CNN's accuracy was not linear. This non-linear trend can be attributed to the random initialization of the CNN's weights before each training session, occasionally leading to suboptimal convergence.

An additional analysis was conducted to compare the performance of the models under varying environmental conditions, such as temperature fluctuations and differing traffic patterns. This analysis revealed that the CNN model maintained its accuracy more consistently across different conditions, indicating its

robustness and adaptability. Furthermore, the inclusion of synthetic data in training the CNN model contributed to its superior performance, as it allowed the model to learn from a more diverse set of examples. Future research should focus on expanding the range of synthetic data and exploring additional ensemble techniques to further enhance prediction accuracy.

Despite achieving high accuracy with the CNN model, with the highest accuracy reaching 0.94, this most accurate method still falls short of meeting the OIML R-134 recommendation by 4.4%. Furthermore, the results show that more static data could be needed for the learning phase. Having 1000 static samples which were augmented might not be sufficient to reach the OIML R-134 recommendation.

In summary, the results indicate that while traditional methods such as IJS RF and AVERAGE(IJS, SIWIM traditional) perform well with limited data, convolutional neural networks (CNNs) demonstrate superior performance as more data becomes available, despite some variability in their convergence. In addition, a sufficient number of training examples is needed to approach the desired OIML R-134 recommendation.

6 Conclusion and Discussion

In this study, a performance comparison of various axle weight prediction algorithms using time-series data collected from 10 sensors positioned on the Lopata bridge was conducted. The algorithms evaluated encompassed traditional machine learning models, such as random forests, and advanced deep learning techniques, notably convolutional neural networks.

The major findings reveal that CNNs achieved significantly better results in predicting axle weights during the latter months of the experiment. The CNNs' ability to adapt to and learn from complex patterns within the time series data was a key factor in their superior performance. Despite achieving high accuracy with the CNN model, reaching a peak accuracy of 0.94, this method still falls short of meeting the OIML R-134 recommendation by 4.4%.

Overall, there are three implications of this study. First, it demonstrates the potential of deep learning techniques to enhance the accuracy of axle weight predictions where sufficient data is available, thereby facilitating more reliable infrastructure management. Second, for smaller datasets, it is more effective to use classical machine learning systems in combination with methods like SIWIM traditional. Third, it provides a valuable benchmark for researchers and practitioners, guiding the development and implementation of more effective axle weight prediction systems.

To achieve the OIML R-134 recommendation, two options are possible:

- Just add more data - if the trend continues, adding another half a year of measurements would enable achieving the standard. Another option would be to apply measurements on a bridge with more traffic.
- Improve the methods by incorporating advanced ensemble techniques.

To introduce the ensemble approaches, one potential improvement involves modeling each sensor individually. This approach entails building a separate CNN model for each of the ten sensors, allowing for more specialized and potentially more accurate predictions from each sensor's data. By focusing on the unique characteristics and data patterns of each sensor, the models can be better tailored to capture specific nuances in the time-series data.

After developing individual models for each sensor, the next step would be to combine the predictions from these models into a single final prediction. This can be achieved using an ensemble method, such as a random forest classifier. The random forest classifier would take the ten individual predictions (one from each sensor model) as input features and produce a consolidated final axle weight prediction.

This method not only holds the potential to improve the accuracy and robustness of the axle weight predictions but also provides a scalable framework that can be adapted to different datasets and sensor configurations. Future work should explore the implementation of this approach, including the optimization of individual sensor models and the integration of their predictions through an ensemble method.

By advancing the CNN model in this manner, it is anticipated that the performance gap relative to the OIML R-134 recommendation could be further reduced, bringing the predictions closer to the required accuracy levels with a smaller amount of data and enhancing the overall efficacy of the axle weight prediction system.

Abstract

This paper presents a comparative analysis of feature- and embedding-based approaches for audio-visual emotion classification. We compared the performance of traditional handcrafted features, using MediaPipe for visual features and Mel-frequency cepstral coefficients (MFCCs) for audio features, against neural network (NN)-based embeddings obtained from pretrained models suitable for emotion recognition (ER). The study employs separate uni-modal datasets for audio and visual modalities to rigorously assess the performance of each feature set on each modality. Results demonstrate that in the case of visual data NN-based embeddings significantly outperform handcrafted features in terms of accuracy and F1 score when training a traditional classifier. However, for audio data the performance is similar on all feature sets. Handcrafted features, such as facial blendshapes, computed from MediaPipe keypoints and MFCCs, remain relevant in resource-constrained settings due to their lower computational demands. This research provides insights into the trade-offs between traditional feature extraction methods and modern deep learning techniques, offering guidance for the development of future emotion classification systems.

Keywords

emotion recognition, embeddings, hand-crafted features

1 Introduction

Automated emotion recognition (ER) often focuses on two modalities – video and audio. This is akin to human emotion recognition, as we heavily rely on audio-visual characteristics, such as facial expressions and audio cues, to deduce emotional state [7]. Both audio and video are relatively simple to obtain using sensors, as such sensors are unobtrusive and easily available (e.g., webcameras) and can be used to train machine learning (ML) models for emotion recognition.

In the past decade deep-learning (DL) approaches achieved state-of-the-art (SOTA) results in many domains, including emotion recognition [16]. However, despite the superior performance of such models, many doubts have been cast on their black-box nature, lacking explainability and interpretability of the internally derived features [9]. Furthermore, while some research suggests superior performance of embeddings compared to traditional features [20], this is not universally agreed upon [8], especially when taking into account potentially much higher computational complexity of deriving embeddings with deep artificial neural networks (ANNs).

Our research question is thus, whether it is better to compute embeddings using SOTA pretrained DL models instead of using hand-crafted features, as ANN embeddings promise to increase detection accuracy at the cost of interpretability and computational complexity. In this work we compared the performance of hand-crafted features and embeddings obtained with pretrained SOTA models for the down-stream task of emotion recognition. We independently compared ER performance of audio and video modality, using established benchmark datasets for each. Handcrafted features were chosen based on literature and embeddings were computed with task-suitable pretrained models available in existing Python libraries. Both were formatted in a way that allowed us to then train a set of traditional ML models, listed in Section 3.3, for ER, using hand-crafted features, embeddings, or a union of both as inputs.

2 Related Work

Performance comparison of hand-crafted features and learned embeddings has been discussed in depth in computer vision domain. Schonberger et al. [15] demonstrated that hand-crafted features (e.g., SIFT) still perform on par or better than learned embeddings in image reconstruction. They warned of high variance across datasets when using learned embeddings as features. Similarly, Antipov et al. [2] reported similar performance of hand-crafted features (e.g., HOG) and learned embeddings when classifying pedestrian gender from images using small datasets. They also highlighted superior generalization performance of embeddings across (unseen) datasets. In emotion recognition from audio, Papakostas et al. [13] compared using hand-crafted MFCC-based features with embeddings from a custom convolutional neural network (CNN) trained on spectrograms. The latter slightly outperformed hand-crafted features by 1% on average in terms of F1 score, again showing similar performance. Ye et al. [21] recently showed that using a union of both hand-crafted features and learned embeddings achieves superior performance in user identification, compared to using each input individually.

There is moderate (but not universal) agreement in recent literature that performance between hand-crafted features and

learned embeddings is similar, however, most work comparing their performance is limited to a single modality or task. We compared performance between two different modalities for the task of ER and investigated potential performance improvements of feature-level fusion (hand-crafted + embeddings).

3 Methodology

Our task consisted of two parts – hand-crafted features and embeddings computation, and ER model training for classification. Both were done on (separate) audio and visual modality and will be described per-modality in the following sections.

3.1 Datasets

As mentioned previously, the ER task is most-often audio-visual, so we decided to use an audio and a visual dataset to independently evaluate the performance of different feature sets. While many datasets exist that contain both modalities, they often have a problem of imprecise coarse emotion labelling [18], as labels are video-based, while emotions can be exhibited and changed in much shorter windows. Splitting video into frames yields a large number of (different) instances with the same label, so we wanted a dataset with individual image labels. As our focus was on comparing the performance of hand-crafted and embedding-based features, we chose two well-established benchmark datasets dedicated to audio and visual emotion classification. These datasets contain short audio clips and individual images with precise short-term and per-frame labels, circumventing the mentioned per-video labelling problem.

3.1.1 Audio Dataset. For evaluation on audio data we decided to use the crowd-sourced emotional multimodal actors dataset (CREMA-D) [4]. It contains short clips of 91 actors between the ages of 20 and 74 coming from a variety of races and ethnicities, who exhibited six different emotions (*Anger, Disgust, Fear, Happy, Neutral, Sad*). Each actor produced about 80 clips (small variation), saying specific sentences exhibiting different emotions. The distribution of labels was balanced, each class representing approx. 16% of the data. The intended emotions were verified with 2,443 crowd-sourced human raters as baseline. These raters predicted emotions based on audio only, video only, or both, achieving 40.9%, 58.2% and 63.6% recognition of intended (acted) emotion respectively.

3.1.2 Visual Dataset. For visual data we chose the extended Cohn-Kanade dataset (CK+) [11], which a staple dataset in ER evaluation from facial expressions. It contains images of 118 adults, aged between 18 and 50, again of different ethnicities. Participants were instructed to perform a series of 23 facial displays, relating to one of seven emotions (*Anger, Contempt, Disgust, Fear, Happy, Sad, Surprise*). The distribution of classes in CK+ is not balanced – *Surprise* is the majority class at 25% and *Contempt* the minority class at 6%, with others in between. This distribution also changes between subjects. CK+ images were reshaped to 48x48 pixels, put in grayscale format and cropped using frontal face Haar cascade classifier [1] as part of preprocessing. The emotion labels were validated by experts via facial activation unit rules (e.g., *Happy* = Activation unit 12 must be present = Lip corner puller active).

3.2 Feature Computation

For selection of hand-crafted features we relied on literature and previous work in ER for each modality. For embeddings on the other hand, we chose SOTA pretrained models trained for related tasks. We extracted embeddings at a model-specific point before the learning layers, and formatted them using principal component analysis (PCA) in order to reduce their dimensionality while maintaining the relevant information.

3.2.1 Audio Features. MFCCs are historically well-established in ER from audio [10], as they give a good approximation of the human auditory system's response. For each audio clip, we computed a common set of statistical aggregate features (averages, standard deviations) for MFCCs, Root Mean Square (RMS) energy (volume), Zero-Crossing Rate, Spectral Bandwidth, Spectral Contrast, and Spectral Roll-off, using the `librosa` python library.

For embeddings we decided to investigate models pretrained on similar audio tasks (e.g., emotion recognition) and use them to the point where embeddings are available, which typically means the upper part of the ANN architecture, responsible for computation of embeddings representing the features. Three pretrained models were investigated in our evaluation, all based on the wav2vec2 architecture, which is a self-supervised model for learning speech representations proposed by Facebook AI Research (FAIR) [3]. Full wav2vec2 pretraining framework comprises a latent feature encoder, a context network using the transformer architecture, a quantization module and contrastive loss (pre-training objective). For our purposes the feature encoder is important, which is a 7-layer 1D CNN reducing the dimensionality of audio inputs into a sequence of feature vectors. The initial model version was pretrained on the LibriSpeech dataset, another version was fine-tuned on IEMOCAP dataset specifically for ER, and finally a large general cross-lingual model (XLSR) was trained on millions of hours of unlabeled audio data in 53 (later extended) languages [5]. These three variants were used to extract their corresponding embeddings. Since the input data from CREMA-D is of inconsistent shape (varying by < 1 sec), we had to employ an additional adaptive average pooling layer to ensure consistently shaped outputs. We designed this pooling layer so that we lost minimal information (short segment length for pooling) and the outputs were then flattened. PCA was employed to subsequently reduce them to 10 dimensions. The number of dimensions was chosen arbitrarily and could be changed, however, we believe that 10 dimensions offer a good balance between retained information and computational (and spatial) requirements. Moreover, this number of PCA components is on the same order of magnitude as the number of hand-crafted features, making them more comparable.

3.2.2 Visual Features. For visual features, we focused on the movement of specific facial keypoints, such as the corners of the mouth and eyebrows, which form the basis of the Facial Action Coding System (FACS) – a taxonomy that categorizes human facial expressions based on muscle movements [6]. We employed the MediaPipe (MP) framework [12] to extract values representing the activation of various facial blendshapes, which correspond approximately to the regions defined in FACS. In this paper, we classify MediaPipe features as "handcrafted" because, despite being neural network-based, they quantify predefined facial areas with human-interpretable metrics. This contrasts with CNN-based embeddings, which capture patterns without direct interpretability.

For comparison, we used embeddings from two pretrained models: FaceNet [17] and EfficientNet [19] from the HSEmotion library [14]. FaceNet architecture is based on GoogleNet, which is a variant of deep CNN, and is trained using triplet loss. It

was optimized for facial recognition, verification, and clustering. EfficientNet comprises several inverted bottleneck convolutional residual blocks. It achieved SOTA results on the AffectNet ER dataset, while being relatively light-weight. Again, PCA was used to reduce the embeddings to 10 dimensions.

3.2.3 Computational and Spatial Requirements. In order to have a clear overview of the trade-off between computational and spatial requirements of each feature computation method, and their classification performance discussed in the next section, we first report the average times to compute and disk sizes of the output (per one instance) for each method in Table 1.

Table 1: Average time and disk space needed for feature computation using each method.

Modality	Feature method	Avg. Time	Avg. Space
Audio	MFCC stats	**19 ms**	**< 1 kB**
	wav2vec2 LibriSpeech	99 ms	194 kB
	wav2vec2 XLSR	274 ms	258 kB
	wav2vec2 IEMOCAP	101 ms	5 kB
Video	MediaPipe	10 ms	**< 1 kB**
	FaceNet	29 ms	2 kB
	EfficientNet	**2 ms**	5 kB

When interpreting the results in Table 1, it must also be considered that DL-based methods require additional computational time when doing PCA on top of the raw embeddings.

3.3 Emotion Classification

Data splitting is a crucial step in evaluation of ML models, as it must be done in a way to avoid overfitting and provide a robust evaluation of generalization capabilities of a model. The aim of this research was primarily not to evaluate the absolute performance of ER, but rather compare the performance when using hand-crafted vs. embedding features. Therefore it was crucial to consistently ensure that the same data splits and models were used in each experiment, for each of the compared inputs. We decided for the most robust leave-one-subject-out (LOSO) evaluation, always using default model hyperparameters. Such experimental setup minimized overfitting and also gave a good overview of generalization performance of emotion classifiers.

4 Experiments and Results

The outputs of the previous step were used as inputs (features) to train a traditional ML model for emotion classification. We evaluated several options: taking the 10 PCA components of embeddings obtained from each pretrained model as inputs, taking only hand-crafted features as inputs, and taking union of both as input. Each of these cases was evaluated for audio and visual modality separately, using the LOSO experimental setup. Several popular ML models were compared (with default hyperparameters), including k-nearest Neighbours (kNN), Random Forest (RF), Support Vector Machines (SVM) with linear kernel, and eXtreme Gradient Boosting (XGB). We monitored classification accuracy and macro F1 score as metrics of the model performance. All results were compared with baseline majority classifier and are reported as averages across all iterations of LOSO, where majority was always taken from the train data (all except left-out).

4.1 Audio Emotion Classification

As mentioned in Section 3 we investigated the following options as feature inputs:

(1) Hand-crafted statistical features relating to MFCCs
(2) 10-component PCA of wav2vec2 embeddings from a model trained on LibriSpeech
(3) 10-component PCA of wav2vec2 embeddings from a model trained on IEMOCAP
(4) 10-component PCA of wav2vec2 embeddings from a cross-lingual XLSR model
(5) Union of hand-crafted and best-performing embeddings (from above)

These were compared in experiments as described in Section 3.3, using a set of four ML models. Results of best-performing model for each set in terms of accuracy and F1 are given in Table 2. Fused data was acquired by concatenating the feature sets.

Table 2: Best performing models for each feature set and corresponding accuracy and F1 scores for audio data. Note that embeddings were represented with 10 components obtained from PCA.

Feature set	Best model	Accuracy	F1 score
N/A	Majority	0.17±0.00	0.05±0.00
MFCC stats	RF	0.46±0.08	0.43±0.09
wav2vec2 LibriSpeech	SVM	0.47±0.08	0.45±0.09
wav2vec2 XLSR	SVM	0.30±0.05	0.27±0.05
wav2vec2 IEMOCAP	SVM	0.47±0.08	0.42±0.09
MFCC + **best** wav2vec2	SVM	**0.52±0.09**	**0.50±0.10**

4.2 Image Emotion Classification

To stay consistent with the audio experiments we performed the same LOSO experiments described in Section 3.3. We compared model performances using the following features as inputs:

(1) MediaPipe blendshapes
(2) 10-component PCA of FaceNet embeddings
(3) 10-component PCA of EfficientNet embeddings
(4) Union of MP and FaceNet embeddings
(5) Union of MP and EfficientNet embeddings

Accuracy and F1 scores for the best performing models for each set of features are again reported in Table 3

Table 3: Best-performing models for each feature set and corresponding accuracy and F1 scores for visual data. Note that embeddings were represented with 10 components obtained from PCA.

Feature set	Best model	Accuracy	F1 score
N/A	Majority	0.25±0.00	0.40±0.00
MediaPipe	RF	0.62±0.28	0.51±0.29
FaceNet	SVM	0.45±0.30	0.36±0.30
EfficientNet	RF	**0.93±0.16**	**0.90±0.20**
Mediapipe + FaceNet	XGB	0.70±0.28	0.60±0.29
Mediapipe + EfficientNet	XGB	**0.93±0.17**	**0.90±0.21**

4.3 Discussion

From Tables 2 and 3 we can observe that for audio the best performance is achieved when using union of hand-crafted and embedding features, while for visual ER the performance of only embeddings or union is nearly identical. The improvement of feature union is thus generally small, as for visual data we get the same result as using only the best embeddings (1% difference in standard deviation), while for audio data the improvement in

both metrics is about 5% compared to individual feature sets. All results substantially outperform the baseline majority classifiers.

For audio data we can see that the best embedding set (wav2vec2 LibriSpeech) performs nearly the same as hand-crafted features (MFCC stats), which is in agreement with some literature [13]. It is surprising that LibriSpeech embeddings slightly outperform IEMOCAP ones, since the latter were trained specifically for emotion recognition, while the former were not. The subpar performance of XLSR is expected, since it is a more general cross-lingual unsupervised model, while investigated data is spoken in English. For visual data on the other hand the best embeddings (EfficientNet) substantially outperform hand-crafted facial expression features (MediaPipe) and those obtained from FaceNet. This is expected, as EfficientNet was trained specifically for emotion recognition, while FaceNet was trained for face recognition. In terms of ML models, we consistently observed best performance of SVM for ER from audio data, while for video data the best model is not as homogeneous. Importantly, performance of different models (RF, SVM and XGB) was often within 1%.

Another important observation is the relative stability of results across subjects when classifying from audio, with standard deviations around 8%. The same was not observed in the evaluation from visual data, with much higher standard deviations, indicating lower stability and greater variation between subjects.

To address our initial research question, we observed similar performance of hand-crafted features and embeddings from SOTA DL models for audio-based ER, with union of both achieving the best results. The image-based visual ER achieved much better performance with learned embeddings as inputs, while the union of features showed no improvement. However, the cost of hand-crafted features and embeddings in terms of computational power required to compute, and spatial requirements to save, is not the same. While hand-crafted features are usually computed quickly and represented with a few numbers, as reported in Table 1, the embeddings require loading a (commonly large) pretrained ANN, which performs a large number of matrix multiplications, resulting in high-dimensional embeddings (e.g., 64×512). This in turn requires additional dimensionality reduction, such as PCA employed in this work. Our results indicate that for image-based visual ER, the additional cost is worthwhile, due to large improvements in performance, while audio-based ER achieved much smaller improvement, making the use of embeddings from pretrained models less attractive.

Finally, hand-crafted features mostly offer direct interpretability (e.g., audio loudness), while embeddings are commonly black-box in nature, lacking explainability without suitable mechanisms on top. The clear meaning of hand-crafted features can be helpful when training traditional ML models, where feature importance can be compared and subsequently interpreted.

5 Conclusion

In summary we compared using hand-crafted features, embeddings of pretrained SOTA models, or union of both, as inputs for ER models using audio and visual data. We found that embedding-based approach is substantially superior with visual data, outweighing the computational cost – the latter is in fact the lowest when using EfficientNet. For audio data, the improvement was only seen in union of inputs, and was relatively low.

As future work it would be worthwhile to compare merged audio-visual features and embeddings in a single ER problem on the same dataset having both modalities. Furthermore, currently used data was simulated/acted, so interpretation of these results must take that into account. Numbers are expected to decrease on a more realistic dataset, as emotions in everyday life are quite subtle [18]. It would thus make sense to run similar experiments on more realistic data as well, although such data is more scarce.

Abstract

To mitigate distractions during complex tasks, ubiquitous computing devices should adapt to the user's cognitive load. However, accurately assessing cognitive load remains a significant challenge. This study aims to present sophisticated, multi-modal data collection, which can enable accurate estimation of cognitive load using wearable and contact-free devices. A total of 25 participants participated in six cognitive load-inducing tasks, each presented at two levels of difficulty. Simultaneously, physiological and behavioral data were collected from a multi-modal sensory setup, including: Empatica E4 wristband, Emteq OCOsense glasses, an eye tracker, a thermal camera, a depth camera and an RGB video camera. Additionally, participants provided subjective measures of cognitive load by completing standardized NASA Task Load Index (NASA TLX) and Instantaneous Self-Assessment (ISA) questionnaires following each cognitive task. Preliminary statistical analyses were conducted on participant demographics, performance metrics, and the perceived difficulty of tasks, as reported in the completed questionnaires.

Keywords

cognitive load inference, wearable sensors, contact-free unobtrusive sensors

1 Introduction

Human attention is a critical resource that is increasingly targeted by mobile applications, online services, and other forms of digital engagement. In an era of constant connectivity, capturing and retaining user attention has become a primary objective for many technologies. However, as users engage in cognitively demanding tasks, distractions can lead to performance degradation and increased stress. Therefore, to minimize interruptions and maintain productivity, ubiquitous computing systems must become capable of recognizing and adapting to the user's cognitive load in real time.

Cognitive load, defined as the mental effort required to process information and perform tasks, triggers a series of physiological responses in the human body. These responses are largely governed by the activation of the sympathetic nervous system. When cognitive load increases, measurable changes can be observed in physiological markers, including blood pressure, brain activity, eye movements, electrodermal activity (EDA), respiration rate, heart rate variability, etc. Furthermore, changes are also reflected in facial expressions, posture, and other behavioural patterns.

This study seeks to offer a unique multi-modal dataset with a rich set of wearable and unobtrusive sensors to capture the subtle changes that occur with the gradual activation of the sympathetic nervous system. Rather than solely focusing on maximizing data accuracy through the use of numerous devices, this approach also aims to identify the minimum set of sensors required to achieve reliable cognitive load assessment. To that end, rich multi-modal data was collected from a myriad of sensors, including wearables

(OCOsense glasses and Empatica E4 wristband) and contact-free unobtrusive sensors such as an advanced eye tracker, a thermal camera, a depth camera, and an RGB video camera. To the best of our knowledge, no prior dataset exists containing such rich multi-modal data obtained with such an elaborate sensory setup.

2 Related Work

The challenge of cognitive load estimation has been extensively studied across various fields. Significant emphasis has been placed on reducing cognitive load in dynamic environments, such as aviation [1]. Recent research has increasingly focused on transitioning from direct measurements, such as electroencephalography (EEG), to indirect methods of cognitive load assessment. For instance, ocular metrics, including pupil diameter and blink rate, have been shown to accurately estimate cognitive load [2, 3, 4]. Additionally, facial temperature variations have been widely correlated with cognitive workload, providing another non-invasive means of assessment [5, 6]. Novak et al. demonstrated that biometric indicators, such as galvanic skin response and skin temperature, can signal increased cognitive load; however, these measures are insufficient to distinguish between varying levels of cognitive load [7]. Wang et al. demonstrated that visual cues—including face pose, eye gaze, eye blinking, and yawn frequency—can serve as indicators of cognitive load [8].

This research aims to address the complexities of cognitive load estimation by integrating a wide range of psychophysiological signals, offering a more comprehensive approach to this task.

3 Experimental Setup

The objective of our data collection was to capture participants' cognitive load under varying levels of difficulty imposed by cognitive load-inducing tasks. The study was conducted in a quiet, temperature-controlled room, with participants tested individually. At the beginning of each session, participants were seated in a comfortable chair in front of a 24” monitor and given instructions about the experiment and their expected role. The Empatica E4 wristband was then fitted to the participant's non-dominant hand, and the OCOsense glasses for emotion recognition were equipped in line with product instructions.

Data collection was further enriched through the use of unobtrusive sensing technologies, including a Tobii Spark eye tracker (60 frames per second), an Intel RealSense Depth Camera D455 (providing depth data at 30 fps), a Logitech BRIO stream 4k webcam at 10 fps with HDR and noise-canceling microphones and a FLIR Lepton 3 thermal camera delivering a full 160x120 pixel thermal resolution with 8 fps. We used this set of devices to continuously monitor participants throughout the recording session. The experimental setup can be observed in Figure 1.

4 Data Collection Protocol

Prior to the experiment, participants completed a brief sleep questionnaire to gather information about their sleep patterns (e.g., hours slept the night before and usual sleep duration) and rated their levels of fatigue and focus on a scale of 1 to 10.

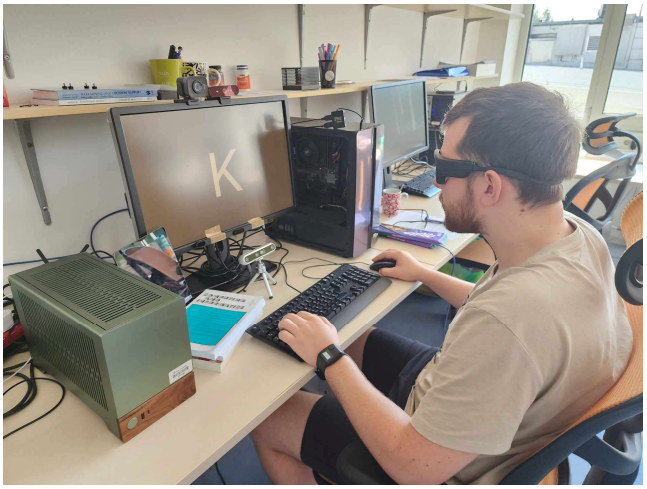

Figure 1: Experimental setup

Calibration data for the OCOsense glasses was then recorded by having participants replicate four facial expressions — smiling, frowning, brow raising, and eye squeezing — three times each. Calibration for the eye tracker followed, during which participants tracked a moving dot with their eyes. This calibration aimed to optimize participant's seating position for accurate eye-tracking.

The experiment's main phase involved participants completing cognitive load-inducing tasks that tested three aspects of cognition: attention, memory, and visual perception. For each cognitive domain, two widely recognized tasks were presented, each with two levels of difficulty (easy and difficult). This design allowed for the differentiation of cognitive load levels. Following each category of cognitive tasks, participants engaged in relaxation tasks that were not expected to induce cognitive load, such as meditation with open eyes, listening to music to relieve stress and passive viewing of aesthetically pleasing images. These tasks provided baseline data for periods of minimal cognitive load.

In summary, each recording session included six cognitive load-inducing tasks (with two levels of difficulty) and three relaxation tasks, totaling 15 tasks. After each task, participants completed the NASA Task Load Index (NASA TLX) questionnaire, a validated instrument for assessing cognitive load across six dimensions: mental demand, physical demand, temporal demand, performance, effort, and frustration [9]. Each question was rated on a scale of 0 to 100. In this study, the unweighted version of the NASA TLX, known as the Raw NASA TLX, was used. Additionally, participants completed a single-item Instantaneous Self-Assessment (ISA) of workload, providing a subjective measure of the cognitive load induced by the task [10]. These questionnaires served as subjective assessments of cognitive load and as reference points for the difficulty of each task [11].

The tasks were implemented using PsychoPy, an open-source software package commonly used in neuroscience and experimental psychology research [12]. For attention-related tasks, participants completed the N-back and Stroop tests. In the N-back task, participants were presented with a sequence of letters and asked to determine whether the current letter matched the one

presented N trials earlier (with task difficulty increasing as N increased) [13]. Participants completed both a 2-back and a 3-back task. In the Stroop test, participants identified whether the word matched the color in which it was written, with the easier version involving two colors (red and blue) and the more difficult version incorporating five colors [14].

Memory-related tasks included a memory game and a question-answering task based on a previously shown image. In the memory game, participants recalled as many words as possible from a set, with the easier version comprising seven words and the more difficult version consisting of 15 words. In the question-answering task, participants focused on an image and then answered questions about it (e.g., remembering the number of particular objects in the image), with the hard version using an image with greater detail.

The visual perception tasks included a "spot the difference" task and a pursuit test. In the "spot the difference" task, participants were presented with two images and were asked to identify as many differences as possible within a one-minute time frame. The difficulty of this task varied, with the more challenging version involving an image that contained greater detail compared to the simpler, easier version. The pursuit test required participants to visually track irregularly curved, overlapping lines. As with the "spot the difference" task, the pursuit test was administered at two levels of difficulty. The more difficult version featured a more intricate image, with longer and more tangled lines, as opposed to the less complex image used in the easier version of the task.

5 Statistics

In this section, we present some descriptive demographic and task-related statistics for the participants involved in the experiment. The average age of participants was 29.28 years, with a standard deviation of 8.31. In terms of educational background, the majority of participants (44 %) had obtained a Bachelor's degree (BSc), followed by those with a Master's degree (MSc), 28 %. A smaller portion had completed only high school (16 %) or had earned a PhD (12 %). Additionally, 60 % of the participants were male.

We then looked at the descriptive statistics derived from the performance of the participants in each task. These indicate that participants performed consistently well on tasks such as the 2-back task, both easy and difficult versions of the Stroop test, the easy memory task (where participants recalled an average of 5 out of 7 words), the easy version of the "spot the difference" task (with an average detection rate of approximately 90 % of all the differences), and both versions of the pursuit test. Notably, participants performed slightly better on the difficult version of the Stroop test, likely due to their increased familiarity with the task.

However, performance was lower on tasks such as the 3-back test (which most participants perceived as highly or extremely difficult), the difficult memory task (with an average recall rate of 39 %), and both the easy and difficult question-answering tasks. The difficult version of the "spot the difference" task also showed lower performance, with participants detecting only 25 % of the differences on average. Consistent performance among subjects (with low standard deviation) was observed across all tasks except for the N-back tasks. Notably, the N-back tasks were always presented first to participants, suggesting that they may have required additional time to adjust to the testing environment and fully engage with the task.

Next, an inferential statistical analysis was performed on the relationship between task scores and various variables of the sleep pattern. To investigate the potential influence of tiredness on performance, responses from the sleep patterns questionnaire were analyzed. A non-parametric Kruskal-Wallis test was performed to determine whether there was a statistically significant difference in overall scores across different levels of tiredness (low, medium, and high). The resulting p-value (0.91) indicated no significant difference in performance between these groups. Thus, tiredness levels did not show a statistically significant impact on performance within a 95 % confidence interval.

Similarly, the effect of focus level (low vs. high) on overall performance was examined using a non-parametric Mann-Whitney test. The p-value was 0.12, indicating no statistically significant difference in performance between low and high focus groups at the 5 % significance level.

Furthermore, the relationship between hours of sleep the night before the experiment and participant performance was examined using Spearman's correlation. The p-value was 0.42, indicating no statistically significant correlation between overall performance scores and hours of sleep the night before the experiment.

The potential influence of participants' highest education level on overall performance was also investigated. To assess this, a non-parametric Kruskal-Wallis test was conducted. The results (p-value of 0.33) indicated no statistically significant difference in performance scores across different education levels among the participants.

Overall, the small sample size may have constrained the ability to detect significant effects. The limited variability in the sample's educational background and other factors likely contributed to the lack of observed differences, emphasizing the need for a larger, more diverse sample to better understand the impact of these variables on cognitive load performance.

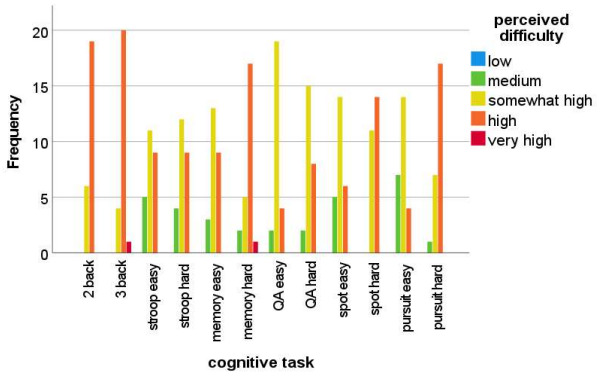

Figure 2: Reported perceived difficulty per cognitive task

As shown in Figure 2, participants consistently perceived the difficulty of the two N-back tasks and the difficult version of the "spot the difference" task as somewhat high or high. This suggests a general consensus regarding the difficulty of these tasks. In contrast, the NASA TLX-based perceived difficulty of remaining tasks, exhibited significant variability among participants.

To assess differences in performance across task difficulties and evaluate the potential for differentiating cognitive load using machine learning models, we conducted additional inferential statistical analyses. The Wilcoxon signed-rank test was used to compare participant performance on the easier and more difficult versions of each cognitive task.

Statistically significant differences in performance were found between the two difficulty levels for all tasks. For the N-back, "spot the difference", and pursuit tasks, participants performed significantly better on the easier versions, indicating that increased difficulty negatively impacted performance. Conversely, for the Stroop, memory, and question-answering tasks, participants performed better on the more difficult versions.

The statistical analysis conducted in this study provides initial evidence supporting the validity of the data collection protocol, particularly with respect to the selection of tasks and task difficulty levels. The tasks chosen for this experiment varied significantly in terms of their cognitive demands, as reflected by the substantial differences in performance between the easier and more difficult versions of each task. These results indicate that cognitive load and performance are task-specific, and the significant differences observed support the feasibility of using machine learning models to differentiate between varying levels of cognitive load.

6 Conclusion and Future Work

This study employs a novel approach to data collection for cognitive load inference by combining psychophysiological data obtained from multi-modal sensory setup, including wearable and unobtrusive contact-free sensors. The decision to utilize a diverse set of devices was motivated by the hypothesis that integrating data from multiple sources could provide a more accurate assessment of cognitive load, while also aiming to identify the minimal sensor configuration required to achieve reliable results. This is particularly relevant in dynamic and high-stakes environments, such as driving, where accurate cognitive load assessment could have life-saving implications. To the best of our knowledge, no prior research has incorporated such a comprehensive and multifaceted setup for cognitive load evaluation.

The statistical analyses conducted thus far offer promising validation for the data collection protocol. The selection of tasks and task difficulty levels proved effective in eliciting a range of cognitive load levels, as evidenced by the significant performance differences between task difficulties.

To further enhance the validity of the data collection protocol, several changes could be implemented in potential subsequent collections. Refining task difficulty levels could offer more granularity in cognitive load differentiation, ensuring a clearer distinction between varying levels of cognitive load. Furthermore, increasing the diversity of participants in terms of age, educational background, and other demographic factors is desirable to enhance the generalizability of the findings.

In future work, the collected data will be processed and utilized to train machine learning models aimed at estimating cognitive load. Ground truth for the machine learning models can be derived from various sources, including perceived task difficulty reported through the standardized questionnaires, the designed difficulty level of the tasks or the participants' performance on the tasks. These machine learning models will leverage sophisticated ML techniques to effectively integrate and analyze multi-modal data, aiming to enhance the accuracy of cognitive load predictions. We also plan to further expand the dataset with another phase of data collection, offering a rich dataset both in terms of modalities, as well as in terms of participants. The collected dataset will serve as a stepping stone towards robust multi-modal cognitive load assessment, allowing for creation and benchmarking of ML models and will be made available to general public after the collection is finalized.

Abstract

Health-related absenteeism, or sick leave, is a complex issue with significant financial and operational implications for businesses. We present a machine learning approach to predict employee absenteeism in a Slovenian company. The study involved preprocessing and augmenting the dataset by incorporating domain knowledge, and evaluating various machine learning models. Gradient Boosted Regression Trees emerged as the most effective model, significantly outperforming the baseline model which merely predicted the previous year's absenteeism rate. Key attributes influencing absenteeism were identified, notably including current absenteeism, performance evaluations, and various job type and location-related features. Results highlight the potential of machine learning in proactively managing absenteeism and offer recommendations for future research, such as modeling absenteeism as a time series and incorporating additional data sources. We also show that the current data is not detailed and granular enough to further improve the results.

Keywords

absenteeism, data analysis, data augmentation, machine learning

1 Introduction

Absenteeism — temporary absence from work due to health reasons — is awidespread issue. In Slovenia, it has been on the rise since 2014 (Figure 1), with an average of 56,128 individuals absent daily in 2022, representing approximately 5.91% of the workforce [8]. This carries substantial financial burdens: direct costs like sick pay and indirect costs from overstaffing, reduced productivity and service quality [2]. The complexity of absenteeism, rooted in personal and organizational factors, makes it challenging to predict and manage effectively [10].

Recent years have witnessed a growing interest in leveraging artificial intelligence (AI) and machine learning (ML) to address the absenteeism challenge [5]. Various machine learning techniques, including neural networks, decision trees, random forests, and gradient boosting, have been employed to predict absenteeism and identify its underlying causes [3, 9]. These studies have demonstrated the potential of machine learning in providing valuable insights for proactive absenteeism management.

This paper presents a case study conducted in collaboration with a Slovenian IT company[1] aiming to improve absenteeism prediction and management. The study includes preprocessing and augmenting the company's employee data by incorporating domain knowledge, and evaluating various machine learning models. The findings highlight key attributes influencing absenteeism and offer recommendations for future research and interventions.

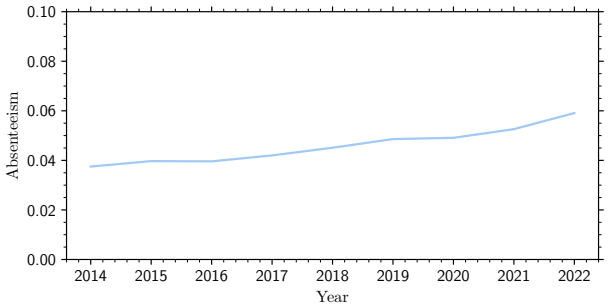

Figure 1: The increase in absenteeism rate in Slovenia between 2014 and 2022 [8]. We can observe a steady increase throughout the years.

The significance of our work extends beyond Company X, offering a blueprint for organizations tackling absenteeism. By showcasing machine learning's efficacy in predicting absenteeism and revealing its drivers, we contribute to the broader field and pave the way for data-driven interventions promoting a healthier, more productive workforce. This aligns with the growing trend of using AI and ML to address complex organizational challenges. Insights from such analyses can aid in strategic workforce planning, optimize resource allocation, and ultimately contribute to a more sustainable and resilient organization.

In section 2 we detail the data and preprocessing, section 3 outlines the methodology, section 4 presents the results, and section 5 discusses the findings and concludes the study.

2 Materials

The data used in our work spanned six years, from 2017 to 2022, and initially comprised 13,798 instances (aggregated employee records) with up to 49 attributes each. They include demographic details, work-related factors, performance evaluations and the current year's absenteeism rate for each employee, but no particulars about sick leave and other personal data.

The initial dataset required substantial preprocessing to prepare it for analysis and machine learning [6]. The data cleaning process involved addressing inconsistencies in attribute values, such as removing extraneous spaces and converting text to lowercase for uniformity. A significant challenge in the dataset was the presence of missing values, denoted by '/'. Their meaning and handling were discussed with a company representative to determine their origins and ensure appropriate treatment. In some

[1]The company asked to remain anonymous, so it is referred to as Company X.

https://doi.org/10.70314/is.2024.scai.7260

cases, missing values were imputed based on the average values of similar instances. For example, missing values in 'Kilometers to work' were attributed to errors in data entry and were imputed using the average value for employees living in the same location and working at the same place. On the other hand, missing values in performance evaluations were due to employee's absence on evaluation days.

The target variable — health-related absenteeism rate in the following year — is a continuous variable ranging from 0 to 1. It signifies the proportion of workdays an employee is absent due to health reasons compared to the total number of workdays. The distribution of this target variable is heavily skewed to the right, with most values clustered near zero, indicating that the majority of employees have low absenteeism rates. However, there exist some outliers with extremely high absenteeism rates (Figure 2).

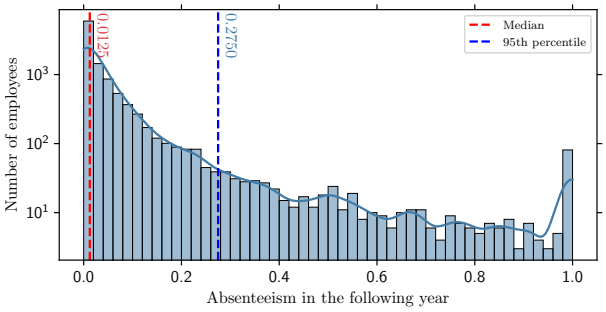

Figure 2: Log-distribution of the target variable. Most workers have very little absence, causing a right-tailed distribution with an "outlier" spike on the right.

The skewed distribution of the target variable has implications for the statistical analysis and machine learning modeling. Therefore, non-parametric statistical tests, such as the Spearman's rank correlation and Kruskal-Wallis test, were employed in EDA and data preprocessing. Additionally, the presence of outliers necessitates careful consideration during model building and evaluation.

The final dataset, comprising 10,347 instances and 42 attributes, serves as the foundation for the subsequent machine learning, where various models are trained to predict absenteeism rates.

3 Methods

The research methodology encompassed a multi-faceted approach, integrating exploratory data analysis, feature engineering, and the application of diverse machine learning models. The ultimate goal was to establish a robust predictive framework for health-related absenteeism, while also ensuring model interpretability to observe actionable insights.

3.1 Exploratory Data Analysis (EDA)

The initial phase involved a thorough EDA to understand the underlying data distribution, identify potential outliers, and uncover preliminary relationships between attributes and the target variable (absenteeism in the following year). Given the skewed nature of the target variable, visualizations like histograms and box plots were complemented by non-parametric statistical tests. The Spearman's rank correlation coefficient was employed to assess monotonic relationships between continuous attributes and the target variable, while the Kruskal-Wallis test was utilized to discern statistically significant differences across groups defined by categorical attributes.

3.2 Data augmentation/Feature Engineering

The original dataset underwent a series of transformations to enhance its suitability for machine learning. This included data cleaning, handling missing values, and the creation of new attributes based on domain knowledge and insights from the EDA. New attributes were engineered based on domain knowledge and statistical analysis. These included indicators for elevated absenteeism, receipt of bonuses or awards, high and low performance evaluations, and absenteeism rates within the employee's team and job type. External factors, such as average absenteeism rates in the employee's residential and work locations, were also incorporated. The feature engineering process was iterative, involving close collaboration with domain experts to ensure the derived attributes were meaningful and captured relevant aspects of employee behavior and organizational dynamics.

3.3 Machine Learning Models

Several well-known machine learning models were employed for absenteeism prediction, including Decision Trees, Linear Regression with L1 regularization, K-Nearest Neighbors (KNN), Support Vector Regression (SVR), Gradient Boosted Regression Trees (GBRT), and Random Forest. Hyperparameter optimization was conducted by using Optuna toolkit [1] to optimize model performance.

3.4 Model Evaluation and Selection

Model evaluation was performed using Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), and coefficient of determination (R^2). The models were trained on past years' data and tested on the subsequent year, with the training set size increasing each year. The MAE provided an intuitive measure of the average prediction error, while the RMSE penalized larger errors more severely. The R2 quantified the proportion of variance in the target variable explained by the model. The models were also compared against a baseline model that simply predicted the previous year's absenteeism, to gauge the added value of the machine learning approach. A baseline model predicting the previous year's absenteeism rate was used for comparison.

3.5 Model Interpretation

SHAP (SHapley Additive exPlanations) values [4, 7] were calculated to interpret model predictions and assess attribute importance. SHAP values provide insights into the contribution of each attribute to the model's output, aiding in understanding the factors driving absenteeism. SHAP values provide a unified framework for interpreting any machine learning model, quantifying the contribution of each feature to the model's prediction for a given instance. By analyzing the SHAP values, it was possible to identify the most influential attributes and their directional impact on absenteeism.

3.6 Data Splitting

To ensure robust model evaluation and mitigate the risk of overfitting, the dataset was split into training and testing sets in a prequential manner (year after year). The models were trained on the training set and their performance was assessed on the unseen testing set for the subsequent year. This comprehensive methodological framework enabled a systematic exploration of

the factors influencing health-related absenteeism and the development of a predictive model to proactively manage this critical issue.

4 Results

The primary objective of our work was to develop machine learning models capable of predicting health-related absenteeism in the subsequent year. The models were evaluated using three key metrics: Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), and the coefficient of determination (R^2). The baseline model, which simply predicted the previous year's absenteeism, served as a benchmark for comparison (Table 1).

Table 1: Model performance averaged year-over-year.

Model	RMSE	MAE	R^2
Random Forest	0.107	0.052	0.344
GBRT	0.108	0.051	0.333
Linear Regression	0.108	0.051	0.331
Regression Decision Tree	0.112	0.051	0.281
KNN	0.121	0.057	0.173
SVR	0.117	0.075	0.215
Baseline Model	0.121	0.051	0.156

As we can see, all machine learning models outperform the baseline model in terms of RMSE and R^2. This indicates their superior ability to explain the variance in the target variable (absenteeism in the following year). While the MAE remains relatively consistent across models, the improvement in RMSE and R^2suggests that the models are particularly effective in handling larger deviations in absenteeism predictions.

To establish the statistical significance of the model improvements, we conducted a paired T-test comparing the predictions of each model against the baseline model. All the selected models demonstrated statistically significant improvements ($p < 0.05$) in RMSE and R^2; this ensures that their superior performance is statistically substantiated and not due to chance.

4.1 Performance Trends and Impact of Additional Data per Employee

To gain deeper insights into model behavior, we examined their performance trends over the years. Figure 3 illustrates the evolution of MAE for each model.

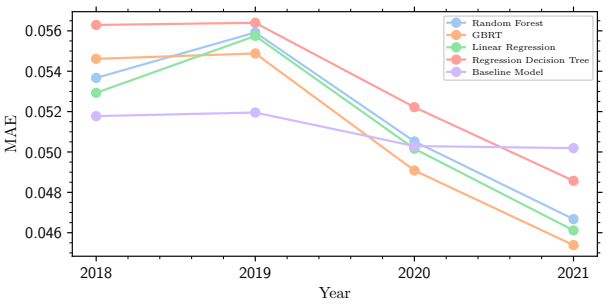

Figure 3: MAE trend over time with additional training data from past years.

Among the evaluated models, GBRT exhibited the best performance, achieving an MAE of 0.045, RMSE of 0.10, and $R^2$of 0.40 on the latest year's data. These results were statistically significantly better than the baseline model, demonstrating the effectiveness of GBRT in capturing the complex patterns underlying absenteeism.

Figure 4 reveals a general trend of MAE improvement for most models in later years, surpassing the baseline model in the final year. This suggests that the models benefit from the increasing amount of training data available in later years. RMSE and R^2charts (not shown) exhibit almost identical properties. It is clear that ML models profit tremendously from increasing amounts of data, as can be expected.

Given the observed performance gains in later years with larger training sets, we explored the impact of incorporating data from previous years. Figure 4 showcases the change in MAE for the final year when models were trained on data from the past year and the past three years, respectively.

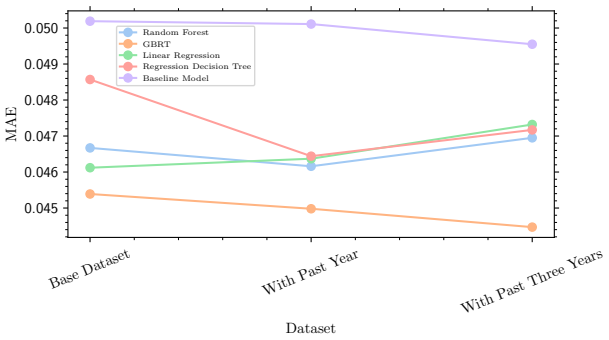

Figure 4: Impact of additional attributes from past years on MAE.

The GBRT model exhibited notable improvement with the inclusion of additional data, achieving an MAE of 0.044, RMSE of 0.093, and R^2 of 0.36. This underscores the value of historical data in enhancing the predictive capabilities of machine learning models for absenteeism and suggests that including even more historical data per employee would be beneficial.

4.2 Interpretability and Additional Insights

Analysis of SHAP values yielded the following key attributes influencing absenteeism:

- Current absenteeism rate
- Performance evaluations
- With respect to the employee's job type and location:
  - Absenteeism rate
  - Proportion of employees with elevated absenteeism
  - Proportion of employees without bonuses

Our findings suggest that absenteeism is influenced by a combination of individual factors (current absenteeism, performance evaluations) and organizational factors (job type, location, bonuses).

Additionally, a rather simple EDA visualisation of functional grouping of employees was quite surprising (Figure 5). Its interpretation can be quite speculative, possibly related to increased job satisfaction or engagement in certain groups. Another, somewhat surprising finding from EDA is that the COVID-19 pandemic did not significantly influence absenteeism rates in 2020, but it may have in 2021 (Figure 6).

Finally, t-SNE visualization of the full dataset shows that employees cannot easily be separated in clusters with similar absenteeism (Figure 7). We can identify some distinct subgroups

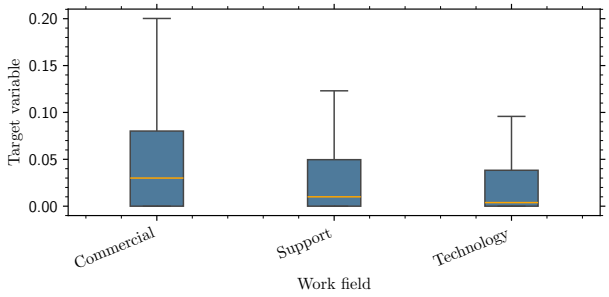

Figure 5: Target variable according to functional partitioning within the company.

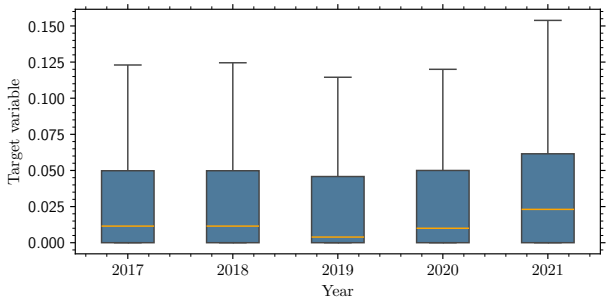

Figure 6: Target variable by year. Note the sharp increase in 2021, possibly attributable to the COVID-19 pandemic.

(like the cluster of red dots on the left), however most data points are quite intermingled. This suggests that with our current set of attributes, we shouldn't anticipate a significant improvement in predictive performance.

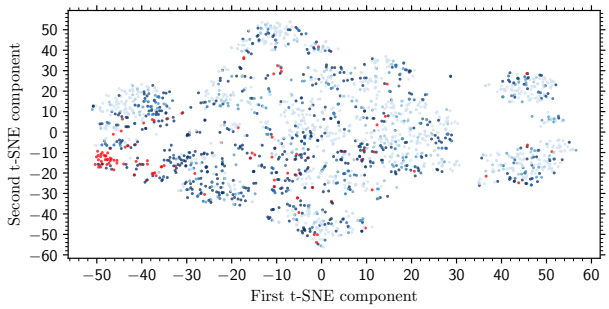

Figure 7: Data visualized in 2D space with t-SNE projection. Red dots represent examples with absenteeism in the next year above 0.25. Blue shades depict examples with absenteeism between 0 (light blue) and 0.25 (dark blue).

5 Discussion and Conclusion

Our work successfully demonstrates the application of machine learning to predict health-related absenteeism. The GBRT model's superior performance highlights its ability to capture complex data relationships, outperforming simpler models and the baseline. Also, identifying key attributes influencing absenteeism, such as current absenteeism, denied bonuses, work type and location, and performance evaluations, provides valuable insights.

The findings align with existing literature highlighting the multifactorial nature of absenteeism. The strong influence of current absenteeism on future absenteeism emphasizes its predictive power, suggesting that past behavior can be a significant indicator of future trends. The negative correlation between performance evaluations and absenteeism suggests that employees with higher evaluations tend to be less absent, potentially due to increased job satisfaction or engagement. The impact of denied bonuses on absenteeism points to the potential role of financial incentives and recognition in influencing employee attendance.

The limitations of our work include the relatively short time span and the potential influence of unmeasured external factors. Future research could address these limitations by: modeling absenteeism as a time series to capture its dynamic nature, incorporating additional data sources such as employee surveys, participation in wellness programs, and (within legal limits) health and personal circumstances data analyzing absenteeism at a finer granularity (e.g., monthly or daily), exploring the inclusion of employee health records and workplace environmental factors in predictive models, and conducting longitudinal studies to track absenteeism patterns over extended periods.

While quantitative improvements of ML model predictions are not overwhelming, the gained insights can enable targeted interventions to reduce absenteeism and promote a healthier workforce. By leveraging ML and data-driven insights, organizations can proactively manage absenteeism, thus improving productivity, financial stability, and employee well-being.

Abstract

Ultimate Tic-Tac-Toe is an interesting and popular variant of Tic-Tac-Toe that lacks available resources for improving gameplay skills. In this paper, we present a semi-automatic system for generating puzzles as a part of a larger tutorial application aimed at teaching Ultimate Tic-Tac-Toe. The puzzles are designed to enhance players' tactical and strategic understanding by presenting game scenarios where they must identify correct continuations. To ensure the quality of generated puzzles we tested the application with a group of volunteers. The results have shown that the number of solved puzzles positively impacted users' ability to reach higher strength levels but had less of an effect on lower levels.

Keywords

Ultimate Tic-Tac-Toe, puzzle generation, minimax algorithm, tutor application

1 Introduction

For centuries, people have enjoyed playing board games like chess and Go. Over time, these games have led to the development of extensive theory and the accumulation of knowledge, helping players navigate their complexity. Today, advanced artificial intelligence (AI) programs such as AlphaZero [14] surpass even the strongest human players, offering new insights into strategies. However, many lesser-known games have yet to be thoroughly explored, despite their popularity. One such game is Ultimate Tic-Tac-Toe, an advanced version of the classic Tic-Tac-Toe. This game is played on a 3x3 grid of local Tic-Tac-Toe boards, creating a global board (Figure 1a). The goal is to win three local boards in a row, while players must make their moves within specific local boards determined by their opponent's previous move. For example, if a player moves in the top-left corner of a local board, the next player must play on the top-left local board. If the designated board is full or decided, the player can choose any other available board. Despite its apparent simplicity, the game has enough spatial complexity that it cannot currently be solved using brute-force methods.

While there are several online implementations of the game, most focus on building strong AI agents; however, There is a noticeable lack of resources aimed at teaching and helping players understand the deeper strategies of the game, which could make the learning curve more manageable for new and aspiring players. Thus, we have created an application that addresses the lack of learning tools available for Ultimate Tic-Tac-Toe. This article places particular emphasis on the puzzle generation aspect of our application, which is designed to enhance players' tactical and strategic thinking.

In Section 2 we present the related work, and in Section 3 we detail the technical aspects of the developed application. In Section 4 we present the implemented agents and their approximate strength. In Section 5 we provide a description of different types of puzzles and the methodology for their construction. In Section 6 we present the evaluation and discuss the results in Section 7. Finally, in Section 8 we present the conclusions and give possible extensions and enhancements for future work.

2 Related Work

There are many implementations of the Ultimate Tic-Tac-Toe available online, mostly appearing as mobile games aimed primarily at entertainment and lacking advanced playing agents [12] [9] [10], as well as web and desktop applications developed to create the strongest possible programs [15] [7] [13]. An example of the latter is an agent based on the ideas of the AlphaZero program [14], currently considered one of the strongest players of this game [13]. During the development of this agent, significant strategies were discovered, which were also useful in developing our application. Some researchers have attempted to solve the game theoretically, but the spatial complexity proved too great to allow for a complete solution [5].

It is important to differentiate between the various versions of Ultimate Tic-Tac-Toe. One variant allows the game to continue playing on already-won local boards, which drastically changes the game's dynamics. In this variant, researchers have demonstrated an optimal strategy for the starting player, who can win in 43 moves [1]. Further research has focused on enabling a more balanced game by introducing random opening moves, which reduces the predictability of forced wins [4]. Despite these interesting findings, research on these variants is not so relevant for us, as it does not contribute to the understanding of the main game.

While there is a lack of educational material specific to our game, much can be learned from related fields, such as chess, which has been extensively researched. The paper by Gobet and Jansen [8] describes a scientific approach to learning chess, which includes methods to improve memory, perception, and problem-solving skills in players. In this context, it focuses on the acquisition and organization of knowledge, including both explicit and implicit learning of tactics and strategies. This approach facilitates a deep understanding of games and the development of more effective learning methods.

Chess also offers highly sophisticated practical solutions from which we can learn a great deal. Platforms such as `chess.com` [2] and `lichess.org` [11] offer extensive resources and tools for learning chess, especially in the areas of tactics and openings. These platforms allow players to learn through interactive lessons, solving puzzles, and studying various openings, which contribute to a deeper understanding of the game and improve playing skills.

https://doi.org/10.70314/is.2024.scai.7299

This approach has proven extremely effective in helping players master complex strategic and tactical concepts in chess.

On the mentioned platforms, the methods for learning tactics are designed to allow players to solve problems based on concrete game situations, which improves pattern recognition and decision-making abilities in real games. Similarly, learning openings involves demonstrating optimal opening moves and their continuations, helping players develop effective strategies at the beginning of the game.

We have applied similar methods in our Ultimate Tic-TacToe application. For example, adapting approaches for learning tactics can help users improve their recognition and solving of complex situations in the game while learning openings helps to understand key opening moves and their impact on the further course of the game. By incorporating these methods into our application, we ensured more effective learning processes and improved the overall gaming experience.

3 Application Details

In addition to puzzle-solving, the app offers a comprehensive learning experience through various other features. It includes AI opponents of different difficulty levels, game analysis, and exploration of effective opening strategies, allowing players to refine their understanding in all phases of the game. The user interface ensures smooth navigation between these modes, making the app a versatile tool for both playing and learning Ultimate Tic-Tac-Toe. By integrating these elements, the app serves as a resource for players at all levels, helping them to deepen their understanding and improve their skills.

To reach a broader audience, the application was developed for both Android and Windows, the dominant operating systems in the market [15]. It uses Flutter components to deliver a responsive and user-friendly interface. Local data storage is utilized for user settings, progress, and puzzle data, ensuring efficient performance and data management.

We employed modern technologies and mobile development practices, including state management patterns, to create an easily expandable app for future updates and enhancements. The entire project is hosted on GitHub, though it is not open-source.

Test versions of the app for Android and Windows are available on Google Drive: https://drive.google.com/drive/folders/1SnO_mN_ZVa2wXd0OGI07kLiYKQTDHuEe?usp=drive_link, while the Android production version is accessible on Google Play Store: https://play.google.com/store/apps/details?id=com.uttt_tutor.

4 AI Agents and Rating System

Playing against intelligent agents allows users to refine their skills by competing against various virtual opponents. The application includes nine different agents, each varying in difficulty and gameplay strategies. These agents are designed using Minimax and Monte Carlo Tree Search [3] algorithms, which provide different levels of complexity and depth in move analysis. The agents and their approximate strengths are shown in Table 1.

To better understand the quality of the agents and evaluate user progress, we need to establish a system for measuring their strength. Since Ultimate Tic-Tac-Toe is not widely popular, there is no established system for rating player abilities. Therefore, we decided to use the chess rating system as an approximation for our agents.

The chess rating system is used to measure the playing strength of chess players. The most commonly used system is the Elo rating [6], which predicts the likelihood of one player winning against another based on their ratings:

$$E_A = \frac{1}{1 + 10^{\frac{R_B - R_A}{400}}},$$

where E_A represents the expected score for player A, R_A is the rating of player A, and R_B is the rating of player B.

Table 1: Table of approximate agent strengths. Each agent played 100 games (50 as X and 50 as O) against the agent one level lower. The results column shows the number of points each agent earned with each symbol, as well as the total score. A win awarded 1 point, while a draw awarded 0.5 points. The last line shows the results of the strongest freely available agent against level 9. It had the same amount of time to think, and they played 30 games.

Agent	Result			Estimated Rating
	X	O	Combined	
Confused Chimp - 1	-	-	-	1
Goofy Goblin - 2	49	49	98	620
Casual Carl - 3	41.5	35.5	77	835
Average Joe - 4	37	25	62	926
Hustling Hugo - 5	39.5	34.5	74	1114
Witty Walter - 6	43	30	73	1293
Thinking Tiffany - 7	35	24	59	1361
Brainy Bob - 8	42,.5	26.5	69	1506
Bossman - 9	36.5	22.5	59	1574
UTTT AI	14.5	12.5	27	1948

5 Puzzle Description and Methodology

In this section, we describe different types of puzzles and the methodology employed to generate them for our game.

5.1 Puzzles

The puzzles in the application are divided into tactical and strategic, with each type of puzzle covering different aspects of the game and helping players improve specific skills.

Tactical puzzles are useful for understanding tactical ideas and are particularly applicable in the endgame and middlegame phases. They focus on specific situations that require precise and thoughtful moves, helping players develop the ability to think quickly and effectively. In total, we generated 1,263 tactical puzzles, distributed across five levels. The number of puzzles for each level is shown in Table 2.

Unlike tactical puzzles, strategic puzzles aim to understand the position and long-term plans. They are instrumental in the opening and middlegame, where it is crucial to recognize strategic ideas and develop plans that provide an advantage as the game continues. There are 50 strategic puzzles available, currently arranged in one level, with the possibility of expansion in the future.

5.2 Tactical Puzzle Generation

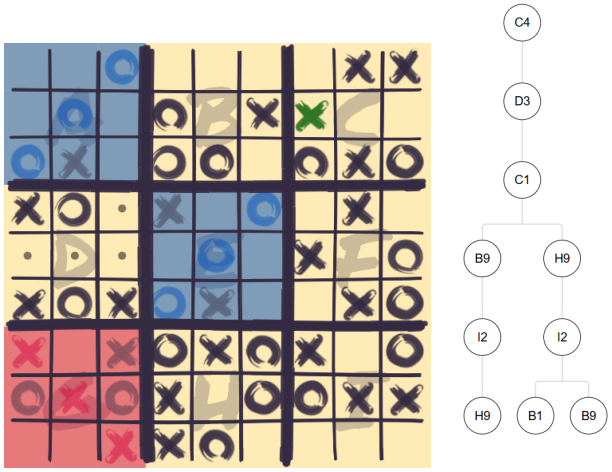
To generate tactical puzzles, we developed a specialized minimax agent that builds a tree of all possible moves leading to victory from the solver's perspective. A key step in this process is the

Table 2: Number of tactical puzzles on each level.

Level	Puzzle Depth	Quantity
1	1	273
2	3	493
3	5	231
4	7	176
5	9	90

selection of tree branches to retain only relevant and correct solutions. It is essential to preserve all of the winner's possibilities while limiting the loser's responses to those that make finding a solution as difficult as possible. Therefore, we select the continuation that allows the longest possible game for the loser while leading to the fewest continuations for the winner.

From the tree, we extract all the correct solutions for the given position. For a high-quality puzzle, it must not have too many solutions. The criterion we set is that the number of solutions must be less than the depth of the puzzle. We also decided to discard all puzzles that have multiple correct continuations for the first move. This way, we avoid trivial puzzles that would be too simple. An example of a level 3 tactical puzzle with its generated solution tree is shown in Figure 1.



(a) Level 3 tactical puzzle. **(b) Solution tree.**

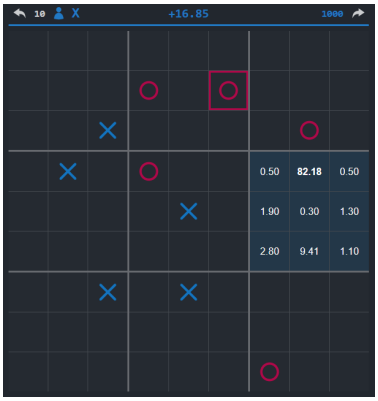
Figure 1: An example of tactical puzzle and its generated solution tree.

The generation of tactical puzzles for different difficulty levels was automated by conducting matches between agents of equal strength, with the search depth of both agents corresponding to the depth of the puzzle we wanted to find. We chose this approach to ensure that the resulting positions were interesting and balanced, as otherwise, the stronger side would usually have an overly obvious advantage at the start of the puzzle which would make it boring to solve.

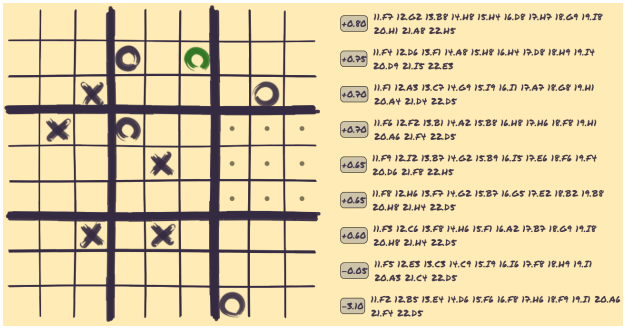
5.3 Strategic Puzzle Generation

Automating the creation of strategic puzzles is impossible without a program that could interpret the given position and simultaneously provide a human-understandable explanation. Additionally, generating strategic puzzles requires an agent with an advanced strategic understanding of the position, which our agents, using relatively simple heuristics, are incapable of. Therefore, we resorted to the most powerful freely available agent [13], which is based on the ideas of the AlphaZero program.

Thus, we generated the strategic puzzles manually. We searched for interesting and instructive positions that arose in games between the aforementioned agent and our stronger programs. We focused on moments when there was a significant deviation in the position evaluation between the two agents. When the agent with better strategic understanding detected an important change, we saved the given position, studied it more closely, and based on our understanding of the game, formulated a solution. The most common examples of such situations involved sacrificing the edge board to gain control over the central board. A basic example of this can be seen in Figure 2.



(a) User interface of the most powerful freely available agent. For the given position, it ran 1000 simulations and assessed the move F2 as the best with an 82% probability. It evaluates the position with a value of +16.85, which means it assigns approximately 58.4% win probability to player X (a value of 0 means a draw, 100 a win, and -100 a loss).



(b) Minimax agent with a search depth of 12. It marks the move F2 as the worst, as it does not recognize the long-term advantage.

Figure 2: Different interpretations of the same position, based on which we built the strategic puzzle.

6 Evaluation and Results

We conducted a quality analysis of the application with 14 volunteers. Their task was to use the app for an extended period to improve their knowledge of the game. We were interested in determining whether using the app had a positive impact on the development of their Ultimate Tic-Tac-Toe playing skills and

whether progress was dependent on motivation or the time spent learning.

To assess individual progress, participants played against the agent at the start of testing to determine their initial skill level. The application then tracked the highest level each user defeated, providing an estimate of their improvement over time. This progress, in relation to the number of puzzles solved, is illustrated in Figure 3. For a more concrete interpretation of obtained level strengths, refer to Section 4.

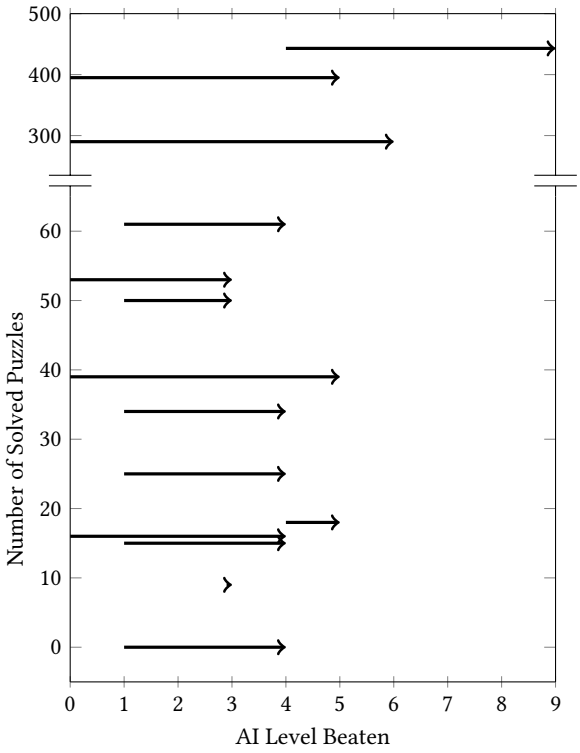


Figure 3: Progress in relation to the number of solved puzzles. Each arrow represents a human tester and indicates the change in the achieved level from the beginning to the end of the application's use.

7 Discussion

The results in Figure 3 indicate that solving more puzzles impacted users' ability to reach higher levels, but had less of an effect on lower levels. This is likely due to the fact that beginners can improve relatively quickly by simply playing the game, whereas advanced players require more effort to progress (eg. it is a lot easier to gain 100 rating points when you are rated 500 as compared to when you are rated 1500).

The reason for this is that at lower ratings, there is generally more room for rapid improvement because the skill gap between players tends to be more pronounced, and beginners can quickly benefit from fundamental knowledge and tactical awareness. As a result, achieving a higher rating initially is easier as players can fix obvious mistakes and exploit weaker opponents' errors.

However, as players reach higher levels, the competition becomes tougher, and the differences in skill become more nuanced. Players at this level are more consistent and less likely to make blunders, so improving further requires mastering advanced strategies, pattern recognition, and deeper positional understanding, making progress slower and more challenging. This reflects the diminishing returns on improvement as you climb the rating ladder.

It must also be mentioned that users were free to use any tools within the app during testing and solving more puzzles did not correlate with longer app usage. For a clearer assessment of puzzle significance, a controlled test focusing solely on puzzle-solving would be more appropriate.

8 Conclusion

In this work, we presented methods for generating puzzles for the game of Ultimate Tic-Tac-Toe. To evaluate the quality of these puzzles, we tracked how the number of solved puzzles impacted individual user progress. Our results indicate a correlation between the number of puzzles solved and the ability to reach stronger AI levels.

However, the evaluation could be refined by focusing exclusively on the puzzle-solving component, isolating it from other functionalities of the application. Additionally, the automation of tactical puzzle generation could be expanded to cover the middlegame phase, rather than being limited to endgame scenarios. Another area of improvement is providing clearer assessments of puzzle difficulty. This could be achieved by implementing a rating system that ranks puzzles based on completion rates, offering a more accurate measure of challenge for each puzzle.

Ethical Consideration and Sociological Challenges in the Integration of Artificial Intelligence in Mental Health Services

Saša Poljak Lukek
sasa.poljaklukek@teof.uni-lj.si
University of Ljubljana, Faculty of Theology
Ljubljana, Slovenia

Abstract [1]
This article explores the transformative potential of artificial intelligence (AI) in the field of mental health, with a particular focus on ethical considerations and social challenges. As AI tools become increasingly sophisticated, their ability to support mental health interventions presents both opportunities and challenges. We discuss the importance of a human-centered approach to AI development and the need for comprehensive ethical guidelines to ensure patient safety and well-being. In addition, this paper explores key social trends such as the evolving dynamics of modern families, aging population, migration and considers how AI can be integrated into these contexts to improve mental health care.

Keywords:
Artificial Intelligence, Mental Health, Human-Centered Approach, Ethics, Modern Family Dynamics, Aging Populations, Migration

1 Introduction

1.1 Artificial intelligence in mental health services

Research on the application of AI in mental health care has shown some positive effects on the treatment of mental health problems [1], including early detection [2,3], providing feedback and personalized treatment plans [4], and developing of novel diagnose tools [2].

AI in mental health services is implemented through models like chatbots, digital platforms, and avatar therapy, enhancing accessibility and treatment options. Chatbots provide therapy via natural language processing [5], while digital platforms support online mostly cognitive behavioral therapeutic interventions [6]. Avatar therapy uses AI to help patients manage conditions like dementia, autism spectrum disorder, and schizophrenia [7].

1.2 The Prospect of artificial intelligence in mental health services

The future orientation underlines the importance of digital health in overcoming challenges such as limited access to services, especially in underserved regions, and outlines measures to ensure equitable access to digital health solutions across the European region [8]. The use of AI in mental health services raises questions about the role of non-human interventions, transparency in the use of algorithms and the long-term impact on the understanding of illness and the human condition [9]. There are also concerns about potential bias, gaps in ethical and legal frameworks, and the possibility of misuse [10,11].

However, there are at least two potentially positive effects of the use of AI in healthcare: Accessibility and personalization of services.

AI offers new mechanisms to reach those who might not otherwise be served. AI-supported tools can improve the early detection and diagnosis of mental disorders [12]. AI chatbots have shown promise in increasing referrals to mental health services, especially for minority groups who are blocked from accessing traditional care [13]. These technologies can provide initial assessments, psychoeducation and even treatment, expanding access to mental health support [12]. AI-driven virtual assistants and wearable devices enable continuous

[1] *This Publication is a Part of the Research Program The Intersection of Virtue, Experience, and Digital Culture: Ethical and Theological Insights, financed by the University of Ljubljana.*

monitoring and personalized care, which could improve patient outcomes [11,14].

The integration of artificial intelligence into mental health services represents a promising avenue for the development of personalized treatment plans through the sophisticated analysis of large datasets, enabling the identification of optimal therapeutic strategies tailored to specific client profiles [15,16]. This data-driven methodology enables the dynamic adaptation of therapy to the evolving needs of the client.

2 Overcoming Sociological Challenges through the Integration of Artificial Intelligence in Mental Health Services

2.1 Modern Family Dynamics

Modern family trends show that family structures and attitudes have changed significantly in recent decades [17]. There is a growing acceptance of different family forms, including unmarried cohabitation, same-sex relationships and joint custody arrangements [18]. These changes reflect an expansion of developmental idealism and increasing support for individual freedom in family choice [17].

On the other hand, there is a growing need for mental health services for families [19]. As the most vulnerable members of the family - the children - are usually also at risk, quick and effective action in family mental health is of great importance. Many families are struggling with various psychological problems. Together with the changing family structure, this means a great burden for every family member. In addition, access to psychologists, psychiatrics and therapists is limited, leading to an acute shortage of mental health professionals worldwide.

The accessibility of services is probably the strongest argument for the integration of AI in healthcare [12]. AI-powered conversational agents can improve the accessibility of mental health services by being available online at all times and in underserved areas, being scalable, reliable, fatigue-free, and providing consistent support, being culturally sensitive to adapt, and helping with education and symptom management.

2.2 Aging Populations

AI offers promising solutions for supporting an aging population, particularly in addressing cognitive decline and mental health challenges. AI applications can monitor vital signs, health indicators, and cognition, as well as provide support for daily activities [20]. With an increasing number of elderly individuals, AI can support mental health care by providing companionship through intelligent animal-like robots (e.g., Paro, Harp seal) and assisting in monitoring and managing conditions like dementia [21,22]. AI can also help in tracking cognitive health and providing timely interventions to maintain mental well-being in older adults. These technologies have the potential to enhance independent living and quality of life for older adults and their families.

2.3 Migration

Migrants often face mental health challenges due to displacement, cultural adjustment and language barriers. AI can help migrants access mental health services by providing culturally and linguistically relevant resources and support. Chatbots and AI-driven platforms can bridge gaps in care by providing immediate help and continuity of care across different regions [23].

Recent research highlights the increasing role of digitalization and artificial intelligence (AI) in migration and mobility systems, especially in the context of the COVID-19 pandemic [24]. While these technologies offer opportunities for improving human rights and supporting international development, they also bring challenges that require careful consideration of design, development and implementation aspects. The integration of AI into migration processes requires a focus on human rights at all stages that goes beyond technical feasibility and companies' claims of inclusivity [24].

3 Ethical Consideration in the Integration of Artificial Intelligence in Mental Health Services

One of the main caveats to the use of AI in mental health is the introduction of new ethical standards to ensure user safety. The approach to integrating AI into services should therefore be human-centered [25]. Any innovation should therefore focus on people in their most

vulnerable position. It is important to assess all risks with sufficient accuracy and avoid misuse of AI as much as possible. The most important areas for ethical consideration when integrating AI into mental health services should be privacy, bias, transparency, security.

Data privacy and security are critical in digital healthcare and require robust measures to protect sensitive information and prevent unauthorized access. Protecting privacy rights and ensuring informed consent are critical to maintaining trust and ethical standards in the use of personal health data [11]. Combining multiple data streams increases the risk of unauthorized use, which exacerbates privacy issues. Ensuring informed consent and maintaining transparency, especially in emergency operations, are critical to addressing these ethical concerns and protecting the rights of participants [26].

The use of AI in mental health treatment raises ethical concerns about bias, particularly among marginalized populations who are already discriminated against and lack access to mental health care. It is uncertain whether AI-assisted psychotherapy can effectively address cultural differences and close treatment gaps in diverse populations [27]. In addition, populations that are traditionally marginalized in fields such as psychology and psychiatry are most vulnerable to algorithmic biases in AI and machine learning [27,28]. These biases limit the ability of AI to provide culturally and linguistically appropriate mental health resources, exacerbating existing inequalities. The persistence of such biases in AI systems not only risks increasing health inequalities, but also exacerbates existing social inequalities and raises critical ethical considerations [9].

The future of artificial intelligence in clinical settings is affected by a significant ethical dilemma concerning the trade-off between the performance and interpretability of machine learning models [29]. The lack of transparency in AI models makes it difficult to detect and correct biases. This underscores the need for greater transparency to ensure ethical and fair clinical decision-making.

In summary, the integration of AI into mental health services requires the establishment of strict ethical standards to protect the safety and privacy of users. A human-centered approach is essential, with a focus on dealing with potential bias, especially among marginalized groups, the risks associated with data privacy and security, and the challenges posed by the lack of transparency of AI models.

4 Conclusion

We propose to define AI as a new ethical entity in the field of mental health [30]. AI represents a novel artifact that changes interactions, concepts, epistemic fields and normative requirements. This change requires a redefinition of the role of AI, which lies on a spectrum between a tool and an agent. This shift underscores the need for new ethical standards and guidelines that recognize the unique status of AI as a distinct and influential actor in the field of mental health.

The integration of AI into services can, on the one hand, provide more efficient and faster solutions to some of the sociological challenges of today's society, but on the other hand, requires a precise and correct definition of the limits within which these models can be used. These efforts aim to bridge the gap between technology and human-centered care and ensure that AI complements, rather than replaces, the therapeutic benefits of human interaction.

Abstract

This paper presents the Optimization Problem Inspector (OPI) tool for assisting researchers and practitioners in analyzing industrial optimization problems and their solutions. OPI is a highly interactive web application requiring no programming knowledge to be used. It helps the users to better understand their problem by: 1) comparing the landscape features of the analyzed problem with those of some well-understood reference problems, and 2) visualizing the values of solution variables, objectives, constraints and any other user-specified solution parameters. The features of OPI are presented using a bi-objective pressure vessel design problem as an example.

Keywords

optimization, black-box problems, sampling, problem characterization, visualization

1 Introduction

Industrial optimization problems often require simulations to evaluate solutions. For example, in electrical motor design [18, 19], assessing the efficiency and electromagnetic performance of a proposed design is done by running a simulator that analyzes the motor magnetic field and flux distribution. Such evaluations are black boxes to the user and the optimization algorithm alike, i.e., the underlying functions cannot be explicitly expressed, which makes the problem hard to understand and solve.

The established way to gain a better understanding of industrial problems is through the analysis of their solutions. Depending on the problem at hand, this can be a challenging task, as industrial problems often have a large number of variables, multiple objectives and constraints [20].

The Optimization Problem Inspector (OPI) presented in this paper is a tool conceived to ease this task for both problem experts and optimization algorithm developers. OPI provides two ways to further the understanding of an optimization problem:

(1) It computes a set of landscape features of the analyzed problem and compares them to those of well-understood reference problems.
(2) It provides visualizations of solutions through the values of their variables, objectives, constraints and any other user-specified solution parameters.

OPI is a web application, implemented by a Python library called `optimization-problem-inspector` included in the PyPi Python package index[1]. It is highly interactive and requires no programming knowledge to be used.

Freely available contemporary software tools for multiobjective optimization, such as DESDEO [12], jMetal [7] (and jMetalPy [2]), the MOEA Framework [8], ParadisEO-MOEO [10], platEMO [17], pygmo [3], pymoo [4], and Scilab [15], provide the implementation of various optimization algorithms and test problems. While the majority of them include some visualization of solutions, the plots are mostly focused on showing algorithm results for the purpose of comparing algorithm performance and not to increase problem understanding. In addition, none of these tools compute additional problem features as OPI does. Therefore, OPI brings a unique perspective to optimization problem analysis and understanding.

Next, Section 2 presents the real-world problem that will be used to showcase the features of OPI in Section 3. The paper concludes with some remarks in Section 4.

2 Real-World Use Case

Our chosen real-world problem is a version of the well-known pressure vessel design problem, first proposed more than 30 years ago [16]. In this work, we adapt the formulation from [5] to handle the pressure vessel volume as a constraint, as well as an objective. We also remove one unnecessary constraint and use the original boundary constraints for the first two variables.

A pressure vessel is a tank, designed to store compressed gasses or liquids. It consists of a cylindrical middle part capped at both ends by hemispherical heads. The pressure vessel has four design variables (see Figure 1): the shell thickness, $x_1 = T_s$, the head thickness, $x_2 = T_h$, the inner radius, $x_3 = R$, and the length of the cylindrical section of the vessel, $x_4 = L$. The two thickness variables are integer multiples of 0.0625 inches, which correspond to the available thicknesses of rolled steel plates, while the length and the radius are continuous. The problem has three constraints, two on the search variables and one on

[1] https://pypi.org/project/optimization-problem-inspector/

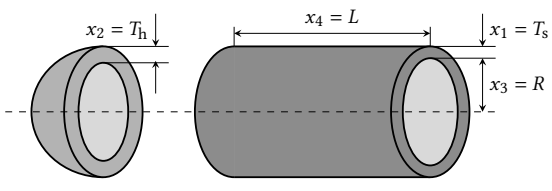

Figure 1: Pressure vessel design variables.

the volume. Its two objectives are to minimize the total costs, including the costs of the material, forming and welding, and to maximize the volume. The problem is formally defined as follows:

$$
\begin{aligned}
\min \quad & f_1(\mathbf{x}) = 0.6224 z_1 x_3 x_4 + 1.7781 z_2 x_3^2 + 3.1661 z_1^2 x_4 \\
& \quad + 19.84 z_1^2 x_3 \\
\max \quad & f_2(\mathbf{x}) = \pi x_3^2 x_4 + \frac{4}{3} \pi x_3^3 \\
\text{subject to} \quad & g_1(\mathbf{x}) = 0.0193 x_3 - z_1 \leq 0 \\
& g_2(\mathbf{x}) = 0.00954 x_3 - z_2 \leq 0 \\
& g_3(\mathbf{x}) = f_2(\mathbf{x}) \geq 1\,296\,000 \\
& x_1 \in \{18, \ldots, 32\} \\
& x_2 \in \{10, \ldots, 32\} \\
& x_3, x_4 \in [10, 200] \\
\text{where} \quad & z_1 = 0.0625 x_1 \\
& z_2 = 0.0625 x_2
\end{aligned}
$$

3 Optimization Problem Inspector Features

OPI is a web application, organized into five functional sections and a help section, providing guidance to the user. OPI expects the user to provide the problem specification and its data—evaluated problem solutions. Then, it generates and visualizes comparisons to artificial reference problems and visualizes the provided data.

Next, we will describe the main features of OPI through its five content sections: problem specification, sample generation, data, comparison to reference problems, and data visualization.

3.1 Problem Specification

In the first OPI section, the user can provide the specification of the industrial problem to be studied. The tool needs this information to properly generate the samples, described in the Section 3.2, and setup the visualisations.

The problem specification must be given in the `yaml` file format and needs to contain some basic information about problem parameters (variables, objectives, constraints) to be included in the analysis. OPI can handle one or more objectives and zero or more constraints. In addition to variables, objectives and constraints, the user can specify any number of other parameters that they want analyzed and visualized, for example, the name of the algorithm that found a solution or the time required to evaluate a solution.

For each of the parameters, the user needs to specify its name and its grouping (whether it is a variable, objective, constraint or something else). For variables, their type (continuous, integer or categorical) and the upper and lower bounds (for non-categorical types) are also required. An example `yaml` file, specifying a constrained multiobjective problem with several variables, is already provided within the tool to guide the user.

For the pressure vessel design problem, we can input four variables (first two are integer and last two are continuous), two objectives and three constraints. Alternatively, we can decide to skip the individual constraints and only use the total constraint violation instead.

3.2 Sample Generation

In OPI, a sample is a set of x-values, corresponding to the variables set in the problem specification section. In other words, a sample is a set of non-evaluated solutions.

If needed, the sample can be generated by the tool itself, based on the variable information provided in the problem specification step. However, this is not a required step in using OPI. A user that already has a set of (evaluated) solutions to work with can skip it and input the data directly (see Section 3.3).

Sample generation requires one to choose the number of desired samples, set to a default of 100, and the sample generation method. Three sample generation methods are supported: random, Sobol and Latin Hypercube, with random sampling being the default. The user may alter the settings of these sampling methods, such as the random generator seed. Selecting the button to generate and download the sample will download it in a `csv`-formatted file.

In the pressure vessel use case, OPI warns the user that not all sample generation methods are appropriate. In fact, the Sobol sampler and the Latin Hypercube Sampler are not compatible with non-continuous parameters. If used nevertheless, they may produce unexpected results.

3.3 Data

In OPI, the data is essentially a set of evaluated solutions, where each solution must contain a value for all objectives, constraints and other parameters included in the problem specification. The evaluation is conducted externally to the tool.

The data needs to be uploaded in a file in `csv` format. If any parameters from the problem specification are missing from the data, the tool will display a warning message. Any data parameters that are not included in the problem specification, are ignored without raising any warnings. When correctly input, the user will be able to view the data they have input, inspecting it in tabular format.

Inputting the data completes the setup stage of the process. The user may then begin generating visualisations to assist them in understanding their problem.

3.4 Comparison to Reference Problems

The first visualization mechanism provided by OPI visually compares the problem to a set of artificial reference problems with known properties. This is conducted by displaying the landscape features of the user-defined problem alongside the same features of each of the reference problems in a parallel coordinates plot. The plot is interactive—the user can highlight some of the problems by brushing along one of the parallel axes. In addition, the feature values can be viewed in a table and downloaded to a file in `csv` format.

The reference problems can be set by the user, however, confined within the collection labelled here as GBBOB, i.e., generalised BBOB, where BBOB stands for the well-known suite of 24 Black-Box Optimization Benchmarking problems with diverse properties [9]. OPI provides a generator of GBBOB problems that match the analyzed problem in terms of the number of variables and objectives and the presence or absence of constraints. For objectives and (optionally) the constraint, any single-objective BBOB problem instance can be used. The user can specify the desired GBBOB problems in the `yaml` format. OPI already contains five GBBOB problems to start.

A problem can be characterized by a large number of features, most hard to interpret by a human. In OPI, we included the following problem landscape features that are understandable to an expert user [1, 11, 13, 14]: `CorrObj`, `MinCV`, `FR`, `constr_obj_corr`, `H_MAX`, `UPO_N`, `PO_N` and a set of neighborhood features. `CorrObj`

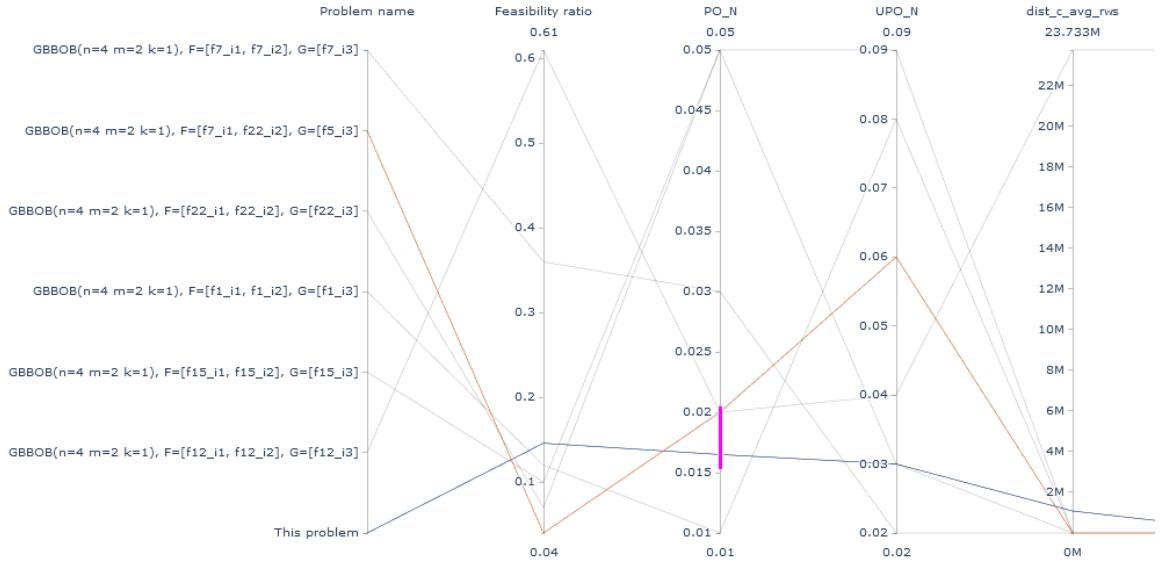

Figure 2: The initial part of the parallel coordinate plot visualizing feature values for the analyzed problem and the chosen set of artificial test problems.

is a feature that shows the correlation between the objectives. `MinCV` represents the minimum constraint violation among all solutions in the population. `FR` represents the proportion of feasible solutions in the population. `constr_obj_corr` presents the maximum correlation between the constraints and all the problem objectives. `H_MAX` is the maximum information content among all objectives. `UPO_N` is the proportion of unconstrained non-dominated solutions, while `PO_N` is the proportion of the constrained non-dominated solutions. The neighbourhood features denoted by `neighbourhood_feats` are a collection of features explaining the neighborhood of solutions, e.g., how many neighbors of a solution dominate the solution, how many neighbors are dominated by the solution, how many are incomparable to the solution, how close the neighboring solutions are, etc. OPI offers a total of 16 features, but the user can choose which to compute and visualize.

Figure 2 shows the initial part of the parallel coordinates plot (as the entire plot would not fit the paper) for the pressure vessel problem. In the comparison, we use the default five GBBOB reference problems as well as a custom created one. We notice that the pressure vessel problem is most similar to the custom GBBOB problem with the first objective equal to the step ellipsoid function f_7, the second to the multimodal peaks function f_{22}, and the linear constraint f_5. This similarity might be due to our mixed-integer problem containing plateaus in the continuous landscape space in which the features are computed, which is similar to the step ellipsoid function, and having linear constraints.

3.5 Data Visualization

In the data visualization section of the web application, the supplied data can be visualized using either a scatter plot matrix or a parallel plot. In both cases, the user can choose which problem parameters to visualize among all those listed in problem specification. Additionally, a simple data filtering that limits any variable between the desired minimum and maximum values is also supported and can be manipulated via the OPI interface in `yaml` format. The parameter used for coloring the solutions, as well as the color map, can also be specified by the user. Both visualizations support interaction and can be downloaded in `html` or `png` format.

3.5.1 Scatter Plot Matrix. The scatter plot matrix consists of n^2 plots for n chosen problem parameters as it contains 2-D scatter plots for all possible parameter pairs. In OPI, the user can apply brushing and linking to select the desired solutions in one or more of the scatter plots. These are then highlighted in all scatter plots in the matrix.

Figure 3 shows such a scatter plot for our pressure vessel problem. This visualization includes data from two sources. The first comes from a random sampling of the search space (shown in light blue) and the second from running the NSGA-II algorithm [6] on this problem for $2 \cdot 10^6$ function evaluations to achieve a good approximation of the Pareto front (shown in black). The two sources are set apart by a custom parameter that is then used for coloring the solutions. Some solutions from Figure 3 are highlighted – see the rectangle in the (x_3, x_1) scatter plot (third from the left in the top row).

These plots clearly show the linear relationship of the near-optimal solutions between x_1 and x_2 as well as x_1 and x_3. When only f_1 and f_2 are chosen, it is distinctively visible that the Pareto set approximation is piece-wise linear and disconnected.

3.5.2 Parallel Coordinates Plot. The parallel coordinates plot shows all chosen parameters as parallel coordinates and solutions as lines in the plot. Similarly as with the scatter plot matrix, interaction via brushing and linking is supported to select solutions that fit the desired values.

4 Conclusions

This work presented the features of Optimization Problem Inspector – a web application to support problem experts and algorithm designers in gaining a better understanding of industrial optimization problems. The tool provides comparisons to well-understood reference problems and interactive and highly-customizable visualizations, which can be exported in `html` and `png` formats.

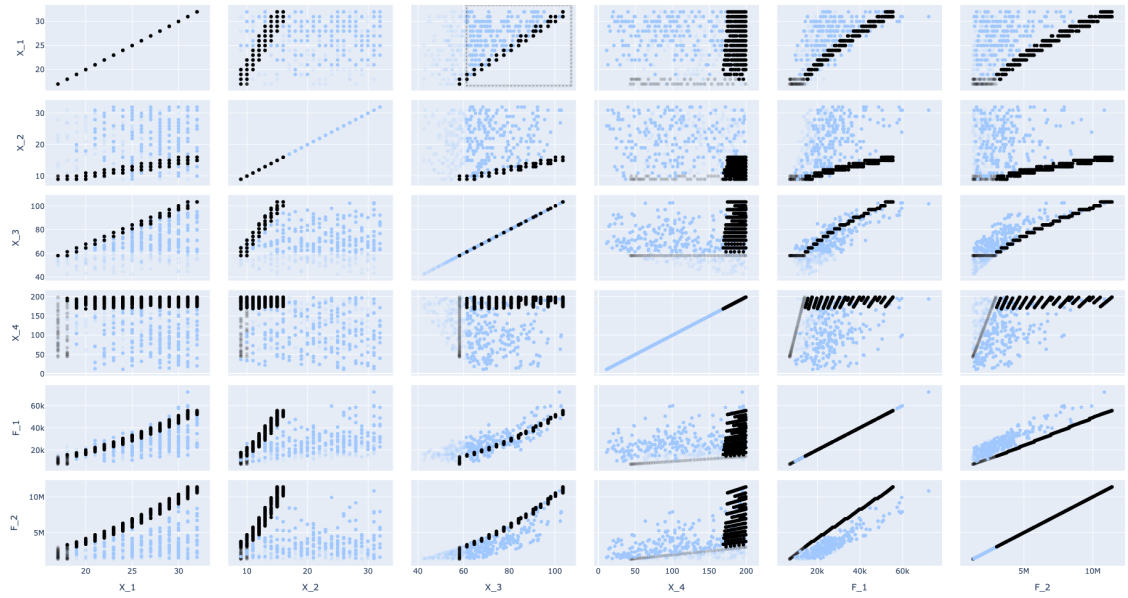

Figure 3: Random (light blue) and near-optimal (black) solutions of the pressure vessel design problem visualized in OPI with a scatter plot matrix containing variables x_1 to x_4 and objectives f_1 and f_2.

Samples can be exported and solutions imported using the standard `csv` format, which makes the data exchange between OPI and various optimization software easy to do. OPI functionality is made to be simple and at the same time flexible. Therefore, it is utilisable by non-experts and experts, alike, providing a wide range of angles from which to view the problems.

Acknowledgements

Abstract

This paper presents a multi-agent system (MAS) for autonomous table football, developed for the FuzbAI competition at the University of Ljubljana. Our system consists of four independent agents, each dynamically assigned specific roles—Goalkeeper, Defender, Midfielder, and Attacker—based on real-time game analysis. This role-based architecture enabled seamless coordination between offensive and defensive strategies, allowing our team to secure first place. We describe the simulation framework used, the processing of sensor data, and the control strategies that allowed the agents to execute precise actions in a dynamic environment. The results highlight the effectiveness of adaptive, role-based decision-making, demonstrating the potential of MAS in real-time, competitive settings.

Keywords

multi-agent system, autonomous table football, role-based strategy, real-time decision making, AI in robotics

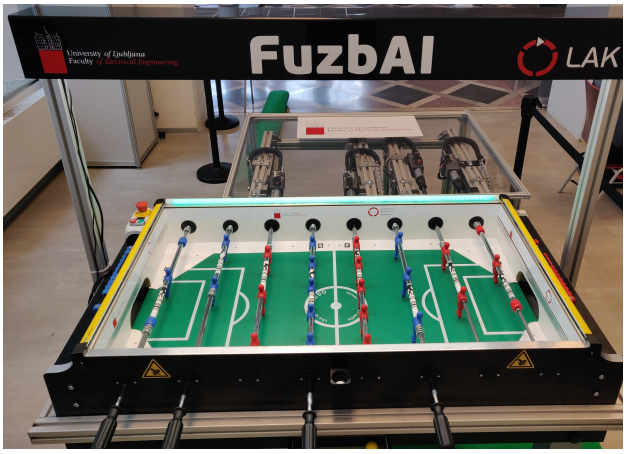

Figure 1: Table setup for the FuzbAI autonomous football competition.

1 Introduction

The FuzbAI competition, held as part of the "Dnevi Avtomatike" event at the Faculty of Electrical Engineering, University of Ljubljana, is a premier contest for students specializing in automation and artificial intelligence [11]. This event challenges participants to develop intelligent autonomous agents capable of playing table football without human intervention. The competition not only serves as a platform for demonstrating technical skills but also fosters innovation in the application of AI and machine learning techniques in real-time environments. Figure 1 illustrates the table setup used in the competition.

The FuzbAI competition is structured in a way that teams must design and implement a fully autonomous system capable of effectively competing against other AI-driven systems. Each match is a test of the participants' ability to integrate advanced algorithms and robotics, simulating the dynamics of a real football game on a miniature scale. The competitive format includes both qualification rounds and knockout stages, ensuring that only the most capable and innovative solutions advance to the final stages.

Our entry into the FuzbAI competition focused on the development of a multi-agent system (MAS), where each of our four rods functioned as an independent agent. These agents were designed to collaborate through a streamlined decision-making process, selecting roles that dictated their actions during gameplay. This strategic approach enabled our team to outperform competitors and ultimately secure first place in the competition.

This paper delves into the development and implementation of our multi-agent system. We will explore the architectural choices, the role-based decision-making strategies employed by each agent, and the overall system's performance in the context of the FuzbAI competition.

2 Competition Setup and System Description

The FuzbAI competition required all participants to develop programs capable of playing table football autonomously. To facilitate this, the competition provided a standardized simulation environment and a set of initial tools that every team used as the foundation for their development. This section describes the simulation framework, the types of data available from the system, and the means by which agents could interact with both the simulated and real game environments.

2.1 Simulation Framework

Participants were provided with a Python-based simulation framework designed to emulate a real table football match, as shown in figure 2. This simulator accurately replicated the physics of the game, including the movement of the ball and rods, and managed the interactions between the environment and the agents controlling the rods. The framework included fundamental functionalities such as ball tracking, rod positioning, and interaction rules, allowing all teams to concentrate on AI development without needing to construct the simulation infrastructure themselves.

One of the key features of the competition setup was that the interaction protocols for the simulator and the physical table were identical. The same signals and commands used to control

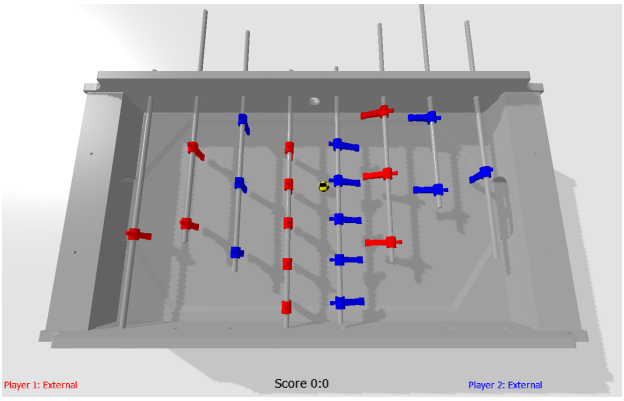

Figure 2: Simulator interface.

the actuators in the simulator were also used for the real table without any modification. This feature ensured that teams could seamlessly transition their algorithms from the simulated environment to the physical table setup, which was used in the final rounds of the competition. As a result, the simulation provided a consistent testing ground that mirrored the actual physical setup, enabling teams to develop and refine their strategies under uniform conditions.

2.2 Sensor Data

Both the simulation environment and the real table provided each team with data from two cameras, one placed on each side of the table. Each camera captured different views of the game, and teams had to decide how to combine the information from both cameras. The data provided by each camera included:

- Ball position: The coordinates of the ball on the 2D plane of the table.
- Ball speed: Velocity of the ball.
- Ball size: Area of the ball in the captured image (in pixels).
- Rod positions: Calibrated position of all rods (in the interval $[0, 1]$).
- Rod angles: Calibrated angle of all rods (in the interval $[-32, +32]$).

This camera data was streamed continuously, requiring teams to process and merge the inputs from both cameras to accurately interpret the game's state. The accuracy and frequency of the data were sufficient to enable real-time decision-making by the autonomous agents, whether interacting with the simulator or the physical table.

2.3 Actuator Outputs

To interact with the environment, each agent could send commands to the actuators that controlled the rods. The system allowed for two primary types of commands:

- Translatory movement: Moving the rod left or right across the table.
- Rotational movement: Rotating the rod to control the angle at which the players struck the ball.

Precise and timely commands were crucial for effective game control, as they enabled the agents to optimally position their figures, strike the ball accurately, and execute defensive or offensive strategies effectively.

3 Related Work

Research on multi-agent systems (MAS) and their application in robotic football has been extensively explored. This section reviews some contributions that have informed the development of autonomous systems for table football and real football.

Moos et al. (2024) [5] developed an automated football table as a research platform for reinforcement learning, highlighting the challenges of transferring learned behaviors from simulation to real-world environments and the need for robust algorithms to handle uncertainties. While reinforcement learning is a common approach in such studies, we did not achieve satisfactory results with it. Therefore, we decided to use multi-agent systems instead. Klančar et al. (2002) [4] investigated cooperative control in robot football (real football) using multi-agent systems, focusing on behavior-based control and dynamic role assignment among robots to optimize performance. Their approach emphasized effective communication for coordination in multi-agent settings. This work particularly inspired our approach to multi-agent systems, where we focused on behavior-based control and dynamic role assignment. Ribeiro et al. (2024) [6] proposed a probability-based strategy (PBS) for robotic football (real football), utilizing real-time data for centralized decision-making without relying heavily on pre-defined plays. Their approach demonstrated flexibility across different environments. Smit et al. (2023) [8] explored scaling multi-agent reinforcement learning (MARL) to a full 11v11 simulated football environment (real football), focusing on computational efficiency and the use of attention mechanisms to enhance scalability in large-scale multi-agent settings. Song et al. (2024) [9] conducted an empirical study on the Google Research Football platform (real football), introducing a population-based MARL training pipeline to quickly develop competitive AI players, highlighting the importance of scalable training frameworks. Scott et al. (2022) [7] examined end-to-end learning in RoboCup simulations (real football), optimizing both low-level skills and high-level strategies through competitive self-play, providing a comprehensive approach to multi-agent training in competitive environments.

4 MAS Approach to Autonomous Table Football Control

In this section, we describe the the methodology of our approach. We describe agent architecture, different agent roles and outline the actions they can take. Then, we discuss the conditions and priorities for role assignment during the game and evaluate the behavior of the system as a whole.

4.1 Agent Architecture

There exist several agent architectures, commonly used in MAS. Approaches, such as [4, 10, 12, 13], use role-based approach for interaction between agents and with the environment. In role-based approach, based on the concepts from role theory [1], the agents are assigned roles which affect their behavior. While the overall long-term goal of the system is typically predefined and does not change, e.g. win a table football match, the current role of an individual agent defines agent's short-term goals, which influences agent behavior, their decision-making process, and how they interact with the rest of the system. Furthermore, separation of agent functionality into independent roles can provide simplification and decoupling of individual tasks, leading to a more modular system, which can simplify and improve the extensibility of the implementation [3].

There exist several approaches to role and behavior implementation in MAS, such as merging different roles, role models and class members [2, 3, 4]. In our implementation, we simplify the architecture by allowing an agent to occupy only a single role at a time, and defining the roles in a way that allows reassigning between iterations of the algorithm without regard to the previous role or state of the agent.

Each role defines a set of possible actions an agent can take. The agents decide which action to take based on their priority and the current environment. More complex roles can be implemented in a stateful manner, meaning the decision on which action to take is dependent on previous actions as well. An agent can only be assigned a single role at a time, but can switch between roles throughout iterations regardless if the particular goal is fulfilled, when appropriate conditions arise. Additionally, every agent must have a role assigned at all times.

An action is a discrete, autonomous task that an agent can take on by making appropriate decisions and acting onto the environment, e.g. by sending commands to the actuators. This advances the agent toward the goal imposed by the current role. An agent can only execute a single action at a time. Additionally, every agent must be actively executing an action at all times.

These concepts were implemented using an Object Oriented approach, as suggested by the authors of the competition. In our implementation, each agent repeatedly executes a fast processing routine. Every iteration, the environment data is updated and role selection for the agent is performed. Then, as the agent decides on a role for that iteration, the appropriate role processing function is called, executing individual actions.

4.2 Role Description

A typical table football setup consists of four rods per player, each with a number of mounted figures. In this implementation, each rod is considered an agent, resulting in a system with four agents for which we define the following roles, typically associated with table football games.

Goalkeeper is the final line of defense, primarily responsible for intercepting the ball before it reaches the goal. Typically the left-most rod, which is nearest to the goal and has a single figure, the goalkeeper follows the ball position using two possible actions: *follow* and *misaligned follow*. The *follow* action simply tries to align the figure on the rod with the current ball position. However, if the velocity of the ball exceeds a predefined threshold, the agent instead attempts to estimate the ball trajectory based on its velocity vector. This estimation is simplified by assuming that the ball maintains a straight-line path. The figure is therefore positioned at the intersection of the rod and the estimated trajectory in an attempt to intercept a fast-moving ball.

The *misaligned follow* action is an augmented variant of the former action, designed to increase the overall defense surface of the defending agents. A common scenario in table football occurs when an attacker attempts to bypass the defenses by slightly pushing the ball parallel to the rod and striking it immediately after. Even though a human player might react fast enough to block such an attack, actuator response times are often insufficient. A defense strategy against such attacks is is to misalign the goalkeeper and defender figures, increasing the defense surface. Here, this is implemented by the *misaligned follow* action, and is activated whenever the ball is relatively slow, in the possession of the opponent and another agent in front of the Goalkeeper is currently in a Defender role. This decreases the chances of the opponent scoring even if the actuators fail to respond fast enough to block this style of attack. Here, communication between the two agents is performed implicitly, as each agent perceives the roles of other agents as a part of the overall environmental state.

Defender is an agent tasked with blocking opponent attacks by intercepting the ball when it is in the opponent's possession or moving towards the goal. This role utilizes a single *follow* action, similar to the Goalkeeper's *follow* action. Whenever the Defender role is active, the agent tracks the position and velocity of the ball, trying to match either its current coordinate or the estimated intersection with the trajectory of the ball. The agent identifies the figure closest to the intersection and attempts to move the rod using minimal amount of movement. This approach allows for faster adjustments during the game, improving defensive efficiency.

Midfielder is a an agent role with the primary task of raising the figures to allow passing the ball from behind the current agent. This role, although simple, is essential in order to avoid accidentally breaking a friendly attack by an Attacker agent behind the current rod.

Attacker is an agent with the task of kicking the ball towards the opponent goal in an attempt to score a point. Unlike other roles, the Attacker role is implemented in a stateful manner. Actions can only happen in a specified order, when the corresponding conditions are met. The role implements *follow*, *kick* and *prevent back-kick* actions.

Whenever the agent is assigned this role, the *follow* action is executed first. During the *follow* action, the agent slightly raises the figures in order to prepare for a kick. The figure closest to the ball is selected and rod offset is adjusted in order to align the figure with the ball. Whenever the agent determines that the alignment with the ball is sufficient, the agent moves onto the next state, the *kick* action. Here, the rod is rotated in order to strike the ball. During this state, it is still necessary to track the position of the ball, as the ball can move significantly within a few iterations of the algorithm. As the rod completes the forward rotation, the agent monitors the position of the ball and assesses if the figure successfully hit the ball. In that case, the next action is set back to *follow*, and the agent is usually assigned a new role according to the environment. However, if the figure missed the ball during the kick, the agent moves onto the *prevent back-kick* action. This final action is meant to prevent an accidental kick in the opposite of the intended direction. The rod is translated sideways and slowly rotated into a neutral position, in order to circumvent the ball. While executing this action, role switching for the current agent is disabled as well.

During execution, the agent aligns the rod position with the ball; however, a perfectly aligned figure results in a straight shot, which is easily defended by maintaining alignment with the ball. A more effective strategy involves kicking at an angle to aim for the goal or create a rebound off the wall, which is harder to defend. This role achieves this by slightly misaligning the figure before and during the kick. The agent computes the angle between the ball's current position and the selected target, with the figure's required misalignment set proportionally to this angle and adjusted by a tunable parameter for fine-tuning. This attack strategy significantly increases the performance of the Attacker role.

4.3 Role Assignment

Individual roles are assigned to agents according to defined assignment conditions and rules. Some approaches use an objective function in order to select a role, often taking role priority into account [4]. In this approach, we instead define a simple set of conditions which, along with role priority, decide on the most appropriate role for a particular agent based on the current state of the environment.

If in a particular instant, more roles fulfill the assignment conditions for a particular agent, the role with higher priority is selected. In this implementation, the highest priority belongs to the Attacker role, followed by the Goalkeeper, Defender and finally the Midfielder with the lowest priority. This ordering is based on the strictness of assignment conditions for each role, and the importance of that particular role. For example, the Attacker role has the strictest selection conditions among all roles, and therefore is assigned the highest priority, while the Midfielder role has a very broad assignment condition and is not as important compared to an Attack agent.

We define the role selection conditions as follows. The Attacker role is selected whenever the ball speed drops below a specified threshold, and the ball is within kicking clearance of the rod. The Goalkeeper role is selected if that particular agent belongs to the left-most rod, closest to the player's goal. The Defender role is selected whenever the ball is in front of the rod. Lastly, the Midfielder role is selected whenever the ball is behind the rod, as the role's only task is to raise the figures to allow the ball to pass forward.

This set of conditions combined with the defined role priority, allow the agents to switch between roles effectively and covers the main functionality required to play the game. Role priority ensures that the agent works toward a correct goal based on the circumstances. For example, any rod, even the Goalkeeper, should attempt to kick the ball if it is close and slow enough, while only the left-most rod should attempt to be the goalkeeper.

4.4 Behavior of the System as a Whole

The system's primary offensive strategy is for the Attacker agents to advance the ball as far forward as possible, ultimately aiming for the goal, while Midfielder agents ensure that they do not obstruct forward passes. During opponent attacks, the systems primary defensive strategy is for the Defender and Goalkeeper roles to intercept the ball. In certain situations, they collaborate to expand the defense surface, compensating for the limitations posed by actuator response times. Once the opponent's attack ends, agents detect the change in the environment and the roles are reassigned to shift the game towards offensive play.

The system's game strategy can be adjusted by modifying parameters such as role priority, assignment rules, or individual actions. For instance, a more defensive strategy can be achieved by tightening the conditions for assigning the Attacker role.

Overall, the implemented algorithm performs well, with the combination of discrete roles resulting in a competent gameplay. However, delays and noise present in measurements, and delays due to actuator response times, sometimes cause the system to miss, e.g. during attacks. The *prevent back-kick* action of the Attacker role proves essential in such situations, performing careful repositioning. Another surprisingly successful strategy is aiming at the goal or the wall during the *attack* action. Even if the ball does not follow the intended trajectory due to measurement noise and system delays, it still considerably increases the attack success rate. Additionally, even though there are no explicit, intentional passes between agents, the strategy of simply passing the ball as far forward as possible is enough for a successful gameplay.

The system overall is sensitive to changes in parameters and requires precise tuning. The simulator, although effective, does not perfectly simulate the physical table, and additional parameter tuning is required when transitioning from the simulator to real-world application.

5 Conclusion

This paper presented a multi-agent system (MAS) for autonomous table football, developed for the FuzbAI competition. Our role-based design allowed each rod to act as an independent agent, dynamically adapting to the game state. This approach enabled effective coordination between offense and defense, contributing to our system's first-place win.

The results demonstrate the effectiveness of a modular, adaptive architecture in dynamic environments, highlighting the importance of robust decision-making and quick role-switching. Future work could include machine learning to predict opponent behavior and optimize strategies, as well as expanding the system to more complex environments. Overall, our MAS showed strong performance in a competitive setting, offering valuable insights for future developments in autonomous systems.

Abstract

Project planning typically refers to the project management step in which project assets, timelines, budgets, milestones, subcontractors, etc., are determined before the new project starts. In this paper, we address infrastructure design projects in the context of a specific company (Elea iC) and explore the idea of using data about past-finished projects to help project managers and project leaders in project planning. A crucial requirement in this context is the ability to evaluate/assess the success of finished/new projects. This paper proposes a solution using a multi-criteria model to evaluate finished projects. This way, we add project success information to the finished projects database, which we shall use in the decision support system being designed to extract knowledge for the new project plan.

Keywords

Project success evaluation, multi-criteria model, decision support systems, data analysis, data mining, project management, project leading tools.

1 Introduction

Infrastructure, such as tunnels, bridges, schools, houses, sewage systems, roads, etc., and its design discipline play a vital role in society. Thus, infrastructure design must have properly and thoroughly defined requirements, objectives, scope and constraints concerning many expert fields such as civil engineering, architecture, geology, geotechnics, environmental engineering, urban planning, and other expert fields [1], [2], [3]. The term design is connected to the process that ends with technical documentation, technical approvals, models, and other deliverables prepared at the end of the design process. Each such process is referred to as the project [4]. The projects are expected to have clearly defined:

- *Goals* defining the project's desired result, e.g., a building permit for a bridge, static analysis of a retaining wall, architectural design for a subway station, geotechnical exploration for a tunnel, etc. [4].
- *Objectives* that support project goals include concrete and measurable project characteristics such as deliverables, milestones, and other steps and strategies to achieve the goals [7].
- *Scope and requirements* concerning project boundaries, e.g., the need for experts, potential subcontractors, technical equipment and other requirements to finish the project.
- *Constraints and limitations* concerning project deadlines, costs, etc. [8].

Besides that, each project should finish with the client's and stakeholders' satisfaction [8].

To achieve the above for the new project, project planning is vital at the beginning of each new project [6], [8]. It is the project management and project leaders' task to recognize and include all these in the project plan so that the work and processes lead to successful project completion.

This study aims to support this process in the context of Elea iC company, an interdisciplinary provider of engineering services and projects in Slovenia [5]. We wanted to include the knowledge obtained from past–finished projects in the project planning process for the new projects. The company collected this data from 2001. The assumptions are as follows:

1. The finished projects in the database offer valuable information for the new project planning phase.
2. The project workflows established in the company and requirements remained similar over the years.

The main challenge related to this question is the new project success assessment and its consideration in light of the available finished project data [7]. Unfortunately, the actual finished projects database does not contain much information about the finished projects' success. To bridge this, we had to construct a project success evaluation model, evaluate finished projects in the database and add this information to the database. The expected result of those steps is a database suitable for applying data-analysis and knowledge extraction methods, such as hierarchical clustering and machine learning [20].

This paper describes the finished project success evaluation component (hereafter called FPSE), which is part of the future decision support system (DSS, [12], [13], [14]) for project planning (hereafter called E-DSS). First, we present the general architecture of the E-DSS, explaining the role and integration of FPSE in its context. In section 3, we present the database of finished projects and its preparation for supporting the configuration of new projects. The evaluation model used and the experimental evaluation of FPSE are presented in sections 4 and 5, respectively. Section 6 concludes the paper.

2 E-DSS Architecture

E-DSS is a DSS under construction to support the project management and project leaders in the Elea iC company (hereafter called "the user") in configuring the new project plan parameters when a new project starts.

The user is expected to define the E-DSS input as shown in Figure 1: the new project objectives, requirements, desires, and expectations. Practically, this means that the user collects all the available new project data by:

- Extracting the new project data from the new project assignment and contracts containing relevant information for the project planning.
- Checking the company and potential subcontractors' state of the resources and assets needed to complete the new project.

Examples of those data include projected monetary value, project scope and goals, project start and finish date, the expert fields needed for project completion, etc.

The E-DSS output (Figure 1) consists of the new project plan configuration together with the corresponding success scores (+S). The configuration comprises the data such as the number of employees involved, the number of subcontractors, work distribution, work duration, the number of pauses, etc. Project success scores are assessed assuming this configuration settings.

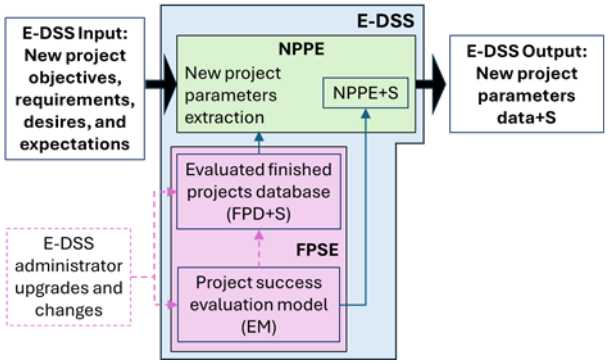

Figure 1: E-DSS architecture

Accordingly, E-DSS is composed of the following components (Figure 1):

- **NPPE** (New Project Parameters Extraction) is the component that extracts the potential new project configuration parameters and corresponding data to support the decision-making. NPPE is currently under construction and is aimed to operate interactively with the user and support: searching for similar projects in FPD+S according to a predefined range, searching the projects by desired success score, project segmentation, and project group identification—unsupervised descriptive analytics and parameter prediction by supervised machine learning methods. The component NPPE+S inside NPPE evaluates the success of the potential new project's configuration parameters obtained. The evaluation is made by EM, which is part of FPSE.
- **FPSE** (Finished Project Success Evaluation) consists of:
  - **EM** (Project success Evaluation Model) for evaluating the new project configuration (described in section 4).
  - **FPD+S** is the database of finished projects with project success evaluations (section 3).

Figure 1 also shows the element **E-DSS administrator** used to upgrade FPSE periodically by upgrading the database of the finished projects or making changes in EM according to the system's operational requirements and expected results.

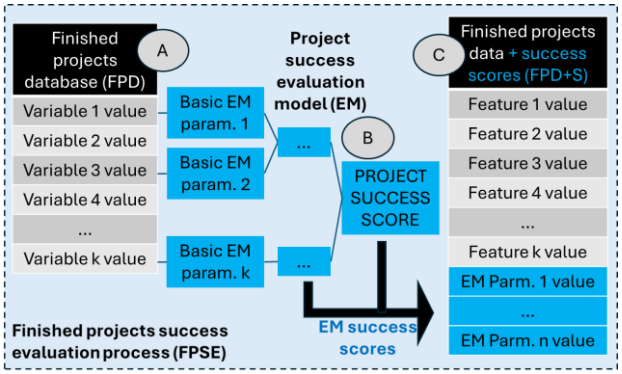

Figure 2: FPD+S development workflow

This paper focuses on the development of FPSE. The workflow is shown in Figure 2, consisting of the following steps:

Step A. Finished projects database preparation (FPD), as described in section 3.

Step B. Project success evaluation model (EM), as described in section 4.

Step C. Finished projects database with EM success scores (FPD+S): The result of the FPSE is the upgraded database of the finished projects with the finished projects' success scores (FPD+S).

3 Data Description

E-DSS is a data-driven system that operates on data from past-finished projects. This data was collected in Elea iC company from the year 2001 to 2023. At the beginning of the data collection, the number of the observed variables was relatively small, but it has grown substantially over the years. At the time of this study, the database contained data on 4704 finished projects, described by 39 numeric variables; 6 of them were date/time/year variables, and 2 categorical variables.

Data preparation (Step A, Figure 2) was carried out as follows:

1. Data cleaning: replacing "Nan" and deleting erroneous data;
2. Outlier's removal using the Interquartile range approach [18];
3. Data imputation: replacing the missing values using a descriptive statistic (e.g. mean, median, or most frequent) along each column or using a constant value [19]. We employed the mean strategy.
4. Sensitive data and information removal. For this reason, all numeric data was scaled to a range between 0 and 1.

We ended up with the database FPD containing data on 3132 finished projects described by 27 numeric variables. The variables describe the main project management characteristics, such as project financial results, workload distribution, number of employees, subcontractors, etc. Table 1 shows the list of all variables together with their basic statistics.

This way, the finished project database (FPD) was prepared for the FPSE component. FPD is the main resource for Exploratory Data Analysis for observing the data and its

properties, such as variable correlations, variable information gain, etc. These operations are invoked interactively by the user in the context of NPPE and are not discussed further in this paper.

4 Evaluation of Projects' Success

The project success evaluation model (EM), developed in Step B (Figure 2), is aimed at:

- The evaluation of the projects in FPD resulting in the FPD+S (Figure 2).
- The evaluation of potential new projects suggested through interaction between the user and NPPE+S (Figure 1).

Project success evaluation involves multiple criteria that have to be aggregated into a single evaluation score. Different criteria might be of different importance and affect the score differently, i.e., with different weights. For this purpose, we chose MAUT (Multi-Attribute Utility Theory) [11], a multi-criteria modelling approach that facilitates both hierarchical structuring of criteria and using weights for the aggregation of scores.

Considering the above requirements, available FPD data and other multi-criteria approaches to project evaluation ([15], [16], [17]), we developed the EM as presented in Figure 3.

EM consists of three components [10]: input parameters, evaluation parameters and aggregation functions.

Input parameters are variables in the leaf nodes of the model:

- *Project Work Concentration*: explains the distribution of the work on the project. If the value is closer to 0 or 1, the majority of the work is done at the beginning or at the end of the project, respectively.
- *Time Reserve*: explains if the project work ended earlier than defined in the contract.
- *Number of Pauses*: the number of times the work on the project stopped.
- *Pauses Time Share*: the ratio between the months the employees did not work and the total number of months.
- *Hour Income*: the ratio between project value and the number of work hours necessary to finish the project.

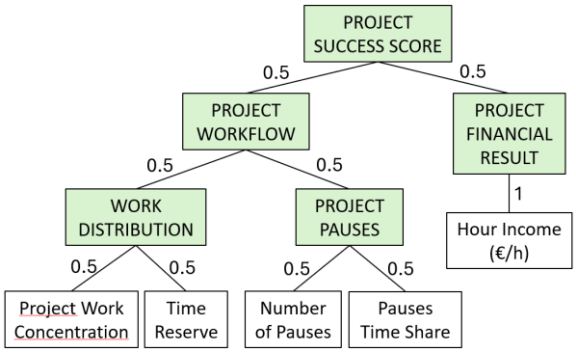

Figure 3: Multi-criteria model for the projects' success evaluation

Evaluation parameters represent outputs of the model*:*

- *WORK DISTRIBUTION*: assesses the characteristics of the work distribution in the project duration.
- *PROJECT PAUSES*: assesses the work pauses.
- *PROJECT WORKFLOW*: combines evaluation parameters WORK DISTRIBUTION and PROJECT PAUSES
- PROJECT FINANCIAL RESULT: assesses the project's success from the financial point of view.
- *PROJECT SUCCESS SCORE*: overall success score, determined by aggregation of all subordinate parameters.

Aggregation functions map subordinate EM parameters to the corresponding parent parameters. Employed is the weighted average function, using weights shown in Figure 3. Currently, weights are chosen to make all parameters equally important.

5 Experimental Evaluation of FPSE

Figure 4 shows an example of evaluating a project from FPD. Input parameters' values (terminal nodes) were obtained from the data base, while evaluation parameters' values (green nodes) were calculated by EM. The example project shows good workflow score (0.75), but has a poor financial score (0.29), both leading to an average success score (0.52) of the project. Several other projects of different types were evaluated in this way, confirming the appropriateness of EM structure and conformance with requirements of potential users. In this way, the quality of EM was assessed on a sample of past projects. Further assessment is planned in the next stages while configuring new projects, where EM's results can be confronted with opinions of project leaders actively involved in the process.

EM already enables evaluation of multiple finished projects. In Step C (Figure 2), FPD was extended by adding five variables corresponding the five Evaluation parameters of EM. All projects in FPD were evaluated by EM, resulting in FPD+S.

Basic statistics of FPD+S is presented by the distribution of the variables in Figure 5. The variables marked with red colour on the x-axis are E-DSS input parameters, the green uppercase variables are those corresponding to success scores, and the blue variables are potential new project parameters. The distribution of the final project evaluation, PROJECT_SUCCESS_SCORE,

(average = 0.52, min = 0.15, max = 0.94) indicates that it well covers the range of possible outcomes and enables the discrimination and sorting of projects.

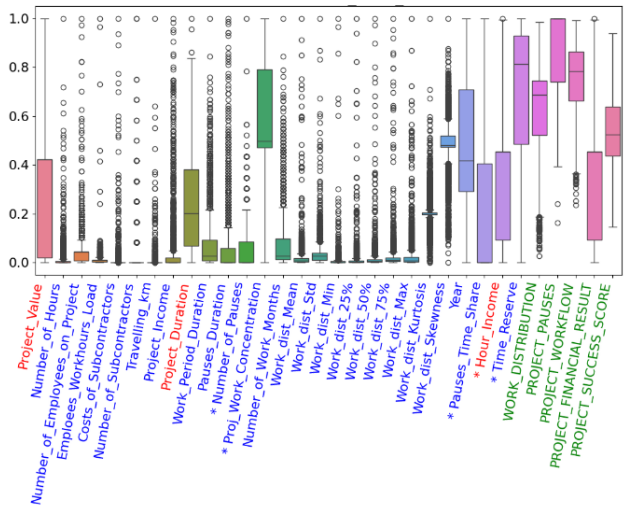

Figure 5: Distribution of the FPD+S features, including EM project success assessments

6 Conclusions

E-DSS is a DSS under construction, aimed at supporting the project management and project leaders' process in the new infrastructure project planning phase. We presented the design and development of the FPSE component, consisting of a multi-criteria project success evaluation model EM and a data base of projects, extended with success evaluation scores FPD+S.

EM has been developed using the MAUT approach and has turned out to be "fit-for-purpose". It employs the data that is available in the projects' database. It meaningfully describes aspects of the project's success and offers practical and functional model for the evaluation of multiple projects in the database.

FPSE is a key decision-support resource for E-DSS. E-DSS will allow the user to interactively search for similar past projects, to filter them according to the success score and simulate the effects of alternative project configurations, ultimately proposing the best one. Approaches based on unsupervised descriptive analytics (clustering) and supervised machine learning methods for prediction of E-DSS output parameters are foreseen for this purpose. Actually, we have already tested hierarchical clustering and decision tree classification methods on FPD+S, and first results are encouraging. We obtained meaningful clusters of past projects and created decision trees for prediction of individual output parameters that may lead to high new project success scores.

Future work will primarily continue by further data analysis and data mining of FPD+S, attempting to design effective algorithms for interactive exploration of past projects and suggesting as good as possible configurations of new projects. On this basis, we shall make a detailed functional specification of the NPPE+S component and design/implement the E-DSS.

Despite that E-DSS considered here is tailor-made for the specific business environment and is bound to the specific data base, the approach seems general enough to be applied to similar environments, projects and processes [9]. This work is a showcase of substantial efforts needed to prepare a corporate database for decision-support, which is often neglected in the literature. The main contribution is a combination of data processing with MAUT-based multi-criteria decision modelling.

Abstract

This paper presents a method for changing the energy use of consumers participating in Demand Response (DR) programs, focusing on peak balancing to improve grid stability. Multiple objectives including costs and risks are considered, and a weighted sum is used to transform them into a single objective. This results in an optimization problem that can be optimally solved. To calculate the costs, the load consumption baseline needs to be established. Since this is challenging and can be exploited, we conduct initial experiments to test whether our method to adjust the baseline can be easily manipulated. We explore an original scenario and three of its variants to examine the effects of various parameters on the optimization outcome. Our results indicate that 1) an excessive emphasis on risk results in no energy change, 2) enforcing a net zero energy change minimizes energy use while still securing the rebate, and 3) without an adjustment period, the consumer is less inclined to increase the load just before the demand period. In future work, we will reformulate some objectives to avoid exploitation and better reflect the real-world needs of DR.

Keywords

multiobjective optimization, mixed-integer linear programming, demand response, baseline consumption, electrical grid

1 Introduction

Peaks in energy demand can strain the electrical grid, leading to inefficiencies and potential failures. A widely used strategy for balancing these peaks is Demand Response (DR), in which the Distribution System Operator (DSO) forecasts future peaks and requests from consumers to adjust their energy use to reduce them. In the peak time rebate DR program [2], consumers receive a rebate if they reduce their load in the demand period. On the other hand, if they commit to respond to the demand, but fail to do so, they can be penalized. It is therefore of utmost importance to accurately assess whether and how much a consumer reduced their load to meet the demand.

The load reduction of a consumer is computed as the difference between its baseline (the amount of energy the customer would have consumed without a demand request) and its actual use [2]. The importance of establishing a baseline and the various ways of calculating it are presented in [5]. Common methods for calculating baselines include simple historical data averages, exponential moving averages and short-term load forecasting techniques. However, baselines can be exploited, e.g., when consumers artificially increase consumption before an event to inflate their baseline and maximize the awarded rebate.

Through the SEEDS project[1], we are developing a methodology for providing energy flexibility services to prosumers – participants in energy markets capable of both producing and consuming energy – in order to enhance grid stability. Machine learning is used to predict the baseline energy usage of prosumers and their flexibility, while mixed-integer linear programming (MILP) is used to optimize the operation of prosumers within their flexibility. Our approach will be tested in the Slovenian pilot, in collaboration with Petrol d.d. and Elektro Celje d.d.

Our work integrates prosumer flexibility into DR optimization, focusing on minimizing costs and risks while limiting energy fluctuations. While the goal is to eventually use this approach on real-world data from the pilot, this paper reports on some initial experiments verifying whether the current problem formulation results in solutions with desired properties. In particular, we wish to test if our adjusted consumer baseline approach can be easily exploited.

Research on prosumer flexibility, optimization techniques, and demand response optimization includes a wide range of approaches [8]. In [3], Balázs et al. quantify residential prosumer flexibility using engineering models and real-world data. Their work provides valuable insight into prosumer behavior and energy management. Capone et al. [4] optimize district energy systems by balancing costs and carbon emissions with genetic algorithms and linear programming, showing significant emission reductions at a modest cost increase. Magalhães and Antunes [7] compare thermal load models in demand response strategies using MILP, finding that discrete control formulations improve computational efficiency. Thus, our methodology is in line with related work while the actual optimization problem (its variables, objectives and constraints) differs from existing ones as it is adapted to our specific use case.

This paper is further organized as follows. In Section 2, we provide a brief overview of the optimization problem, followed by its detailed definition in terms of its variables, constraints and objectives. The optimization approach is explained in Section 3, where we discuss the scalarization technique used to transform our multi-objective problem into a single-objective MILP form and the method used to solve it. The experiments and their results are given in Section 4. Finally, conclusions and further work ideas are described in Section 5.

2 Optimization Problem

The problem formulation in this work assumes a peak time rebate DR program in which the DSO and the consumer have a contract stipulating the following conditions: 1) the consumer can chose whether to respond to a demand request, 2) if the consumer

https://doi.org/10.70314/is.2024.scai.8587

participates in DR, it receives a rebate proportional to the reduced load, 3) if the consumer participates in DR but does not reduce the load by at least 75 % of the required amount, it is penalized, 4) the load reduction is estimated using an adjusted consumer baseline, which takes into account the forecast consumer energy usage as well as its actual consumption before the demand period.

The optimization task is to set the energy consumption of all loads of a consumer participating in DR taking into account their flexibility so that consumer costs, risks and energy fluctuations are minimized. This ensures efficient grid operation while maintaining economic feasibility for the consumer.

To formally define our optimization problem, we first introduce its variables, followed by the constraints and the objective functions we aim to optimize. Finally, we provide an overview of the weighted sum approach, which serves as the scalarization technique to transform all objective values into a single one.

2.1 Variables

A solution is specified by the energy amounts $E_{c,i} \in \mathbb{R}$ for each consumer load $c \in C$ and time interval $i \in \{1, \ldots, n\}$. They correspond to the change of consumption from the forecast one. These are the only variables of this optimization problem.

From these energy amounts and the forecast timetable of energy usage, the resulting energy consumption E_i in time interval $i \in \{1, \ldots, n\}$ is computed as

$$E_i = E_i^{\mathrm{F}} + \sum_{c \in C} E_{c,i}.$$

2.2 Constraints

The energy amounts of a solution need to adhere to two kinds of constraints. The first type are the interval energy constraints:

$$E_{c,i}^{\min} \leq E_{c,i} \leq E_{c,i}^{\max},$$

for each consumer load $c \in C$ and time interval $i \in \{1, \ldots, n\}$. The second are the total energy constraints:

$$E_c^{T,\min} \leq \sum_{i=1}^{n} E_{c,i} \leq E_c^{T,\max},$$

for each consumer load $c \in C$.

2.3 Objective Functions

The three objectives to be minimized in this scenario are the costs, risks and energy fluctuations.

The first optimization objective f_1 consists of all costs associated with the solution and equals

$$f_1 = f^{\mathrm{E}} - f^{\mathrm{R}} + f^{\mathrm{P}},$$

where f^{E} represents the energy costs, f^{R} is the rebate for the recognized load reduction and f^{P} is the penalty that is charged in case the recognized load reduction does not meet the requirements.

The energy costs f^{E} equal the sum of energy costs over all time intervals $i \in \{1, \ldots, n\}$,

$$f^{\mathrm{E}} = \sum_{i=1}^{n} p_i \, E_i,$$

where p_i is the interval energy price.

The solution gains a rebate it the load is reduced in the demand period $\{t^{\mathrm{S}}, \ldots, t^{\mathrm{E}}\}$. Note that the recognized load reduction E_t^{R}, $t \in \{t^{\mathrm{S}}, \ldots, t^{\mathrm{E}}\}$, is computed from the adjusted timetable energy E_t^{A} instead of the forecast one E_t^{F}, where the adjustment is determined by the energy amounts in the adjustment period – the n^{A} intervals before the start of the demand period t^{S}. More formally, the adjusted timetable is computed as

$$E_t^{\mathrm{A}} = \begin{cases} E_t^{\mathrm{F}} - \dfrac{1}{n^{\mathrm{A}}} \displaystyle\sum_{j=t^{\mathrm{S}}-n^{\mathrm{A}}}^{t^{\mathrm{S}}-1} \left(E_j^{\mathrm{F}} - E_j\right), & \text{if } n^{\mathrm{A}} > 0; \\ E_t^{\mathrm{F}}, & \text{otherwise} \end{cases}$$

for all intervals $t \in \{t^{\mathrm{S}}, \ldots, t^{\mathrm{E}}\}$ in the demand period. Then, the recognized load reduction E_t^{R} at demand time interval $t \in \{t^{\mathrm{S}}, \ldots, t^{\mathrm{E}}\}$ is determined as

$$E_t^{\mathrm{R}} = E_t - E_t^{\mathrm{A}},$$

while the total recognized load reduction E^{R} is computed as

$$E^{\mathrm{R}} = \sum_{t=t^{\mathrm{S}}}^{t^{\mathrm{E}}} E_t^{\mathrm{R}}.$$

A rebate is awarded if E^{R} is negative (the consumption has been reduced). If the total recognized load reduction exceeds the total demanded energy reduction E^{T}, the rebate is capped, i.e.,

$$f^{\mathrm{R}} = \begin{cases} p^{\mathrm{B}} \min\left(\left|E^{\mathrm{R}}\right|, \left|E^{\mathrm{T}}\right|\right), & \text{if } E^{\mathrm{R}} < 0 \\ 0, & \text{otherwise} \end{cases}.$$

Finally, a penalty is added to the total costs if the demand has not been met, that is, the ratio between the recognized and demanded energy reduction, E^{D}, in any of the demand time intervals $t \in \{t^{\mathrm{S}}, \ldots, t^{\mathrm{E}}\}$ is lower than 75 %,

$$f^{\mathrm{P}} = \begin{cases} p^{\mathrm{P}} \left|E^{\mathrm{T}}\right|, & \text{if } \dfrac{E_t^{\mathrm{R}}}{E^{\mathrm{D}}} < 75\,\% \text{ for one or more } t \in \{t^{\mathrm{S}}, \ldots, t^{\mathrm{E}}\} \\ 0, & \text{otherwise} \end{cases}.$$

The second optimization objective f_2 represents risks. In order to penalize any changes to the timetable when the risks are high, the objective function is defined as

$$f_2 = \sum_{i=1}^{n} r_i \sum_{c \in C} \left|E_{c,i}\right|,$$

where r_i represents the risk at time interval i.

To penalize unnecessary energy fluctuations, the third objective f_3 averages the consecutive changes in energy amounts for all consumer loads, i.e.,

$$f_3 = \frac{1}{(n-1)|C|} \sum_{i=2}^{n} \sum_{c \in C} \left|E_{c,i} - E_{c,i-1}\right|.$$

2.4 Weighted Sum Approach

Since the optimal solutions to this problem appear to reside in the convex region of the objective space, we use a weighted sum approach to transform all objective values into a single one. The single objective function to be minimized thus equals

$$f = w_1 f_1 + w_2 f_2 + w_3 f_3$$

under the condition $w_1 + w_2 = 1$. The weight w_3 can be set independently of w_1 and w_2 and serves as a measure of limiting the energy fluctuations.

3 Optimization Approach

3.1 Setting Weights in the Weighted Sum

To obtain diverse solutions with the weighted sum approach, a good strategy for setting the weights is needed. While we plan to use a more sophisticated approach for this purpose in future work, these initial experiments were made by choosing equidistant values of w_1 from the interval $[0, 1]$ and defining w_2 as $1 - w_1$. In order to limit energy fluctuations, we set w_3 to 10^{-3}. Smaller weights proved insufficient in limiting the fluctuations while larger weights interfered with the first two objectives, which are more important than the third.

3.2 Linearization

Since all of the objective functions specified in Section 2.3 are either non-linear or contain non-linear parts, specific techniques are required to linearize these objectives and ensure the problem fits the MILP form. In particular, it is necessary to linearize the absolute value of a real variable, the product of a binary variable and a real variable, the minimum of two variables, along with other non-linear function conditions. We use standard approaches to achieve linearization for all these cases [9].

3.3 Tool and Solver

We use the OR-Tools Python library[2] to implement and solve the single-objective MILP problem. The library is a comprehensive tool for solving optimization problems, including linear programming, integer programming, and combinatorial optimization. Specifically, we use the SCIP (Solving Constraint Integer Programs) solver [1] integrated within OR-Tools[3] for solving MILP problem instances.

To solve a MILP problem using OR-Tools and the integrated SCIP solver, the following steps are performed: import the linear solver wrapper, declare the SCIP solver, define the variables with their respective bounds, set the constraints and the objective function and lastly, analyze and display the solution.

4 Experiments

We first conduct experiments using a basic scenario with a single consumer load. Then, we variate some parameters of this scenario to see how they affect the resulting solutions.

4.1 Experimental Setup

The basic scenario has the following parameters:

- Time is represented as 28 15-minute intervals.
- The demand period starts at $i = 13$ and ends at $i = 16$.
- The total required reduction E^{T} equals -8 kWh and the required reduction E^{D} at each interval equals -2 kWh.
- The adjustment period has a duration of four intervals.
- The load change needs to be within $[-3\,\mathrm{kWh}, 3\,\mathrm{kWh}]$ for each interval $i = 5, 6, \ldots, 24$ and is fixed to 0 kWh for the remaining intervals.
- The forecast timetable energy E_i^{F} is constant and equals 12 kWh for all time intervals.
- The total energy constraint is unbounded.
- The risk equals 0.50 for all time intervals.
- All prices are constant: $p_i = 0.25$ EUR, $p^{\mathrm{R}} = 0.50$ EUR and $p^{\mathrm{P}} = 1.00$ EUR.

[2] https://developers.google.com/optimization

[3] https://github.com/google/or-tools/blob/stable/ortools/linear_solver/samples/mip_var_array.py

The three scenario variants differ from the basic as follows. The first scenario variant has no demand. In the second and third scenario variant, the total energy change is set to 0 kWh ensuring the reduction in energy consumption in some intervals is matched with its increase in others. Additionally, the third scenario variant has no adjustment period, i.e, $n_{\mathrm{A}} = 0$.

4.2 Results and Discussion

We discuss here the results of our original scenario and its three variants. They are depicted also in plots in Figures 1 to 4, which show with a black line how the consumer load changes from its planned timetable. Consumer load flexibility at each time interval is shown in gray (there is no flexibility in the first four and last four intervals). The demand period is denoted in red and the adjustment period in blue. In most cases (unless the risk has a large weight), the consumer reduces the load in the demand period enough to meet the required demand and earn the entire available rebate while not incurring any penalty. The amount of this reduction and the energy change outside of this period differ for the various scenario variants.

4.2.1 Original Scenario. When the risk has a large weight, the load does not change outside of the demand period (see the top plot in Figure 1). However, when the impact of risk is minimal (bottom plot in Figure 1), the load is reduced everywhere except during the adjustment period. This strategy artificially increases the perceived load reduction to maximize the rebate, as dictated by the rebate calculation formula.

4.2.2 Scenario Variant #1: No Demand. If the optimization is called without a demand, the result depends on the weighting of the first two objectives. As long as the impact of risk is significant (top plot in Figure 2), the load does not change. Otherwise, the load is reduced to the maximum extent in each interval (bottom plot in Figure 2). This approach minimizes the function f_E, therefore reducing costs. This means that the consumer behavior can change when optimized even if no demand is present.

4.2.3 Scenario Variant #2: Zero Total Energy Change. Due to the zero energy constraint, the consumer makes adjustments solely within the demand and adjustment periods (see Figure 3). During the adjustment period, the user offsets the consumption from the demand period, thereby achieving a maximal rebate. To adhere to the requirement of minimizing risks and fluctuations in other intervals, no additional changes are made, as such actions would increase the objective value.

4.2.4 Scenario Variant #3: Zero Total Energy Change and No Adjustment Period. When the baseline is not adjusted, the load is increased in intervals outside of the demand period, regardless whether they occur before or after it. The specific intervals when this happens depend on the solver and are random as they lead to the same objective function value. An example of such a case in depicted in Figure 4.

The last two variants additionally confirm that the usage of the adjustment period enables exploitation – the entire rebate can be gained with a smaller load reduction in the demand period if the load is increased in the adjustment period.

5 Conclusions

This paper focuses on demand response optimization and the growing role of prosumers in energy systems. A standard MILP framework is used to set the consumer load energies within

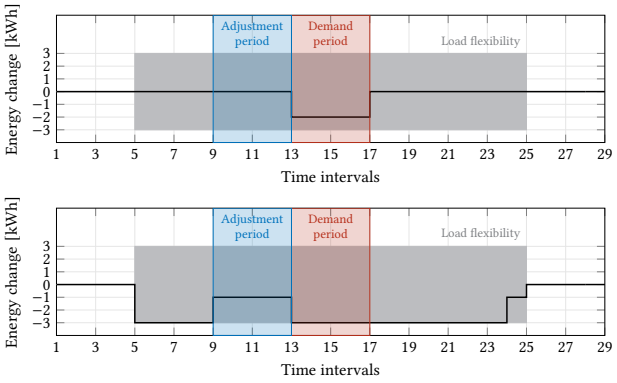

Figure 1: Results for the original scenario with $w_1 = 0.6$ and $w_2 = 0.4$ (top) and $w_1 = 0.8$ and $w_2 = 0.2$ (bottom).

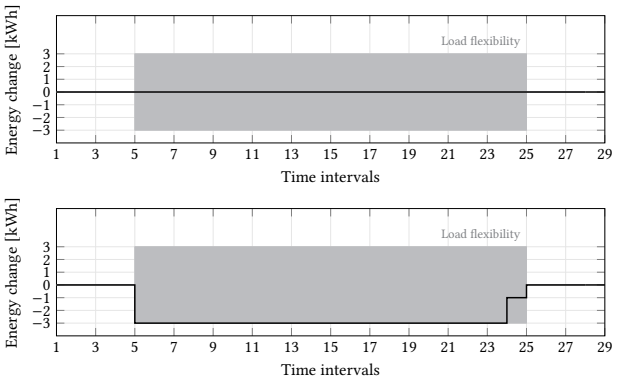

Figure 2: Results for the variant without demand with $w_1 = 0.5$ and $w_2 = 0.5$ (top) and $w_1 = 0.7$ and $w_2 = 0.3$ (bottom).

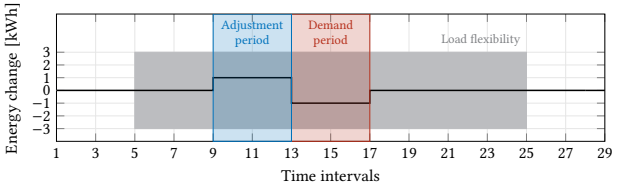

Figure 3: Results for the variant with zero total energy change with $w_1 = 0.6$ and $w_2 = 0.4$.

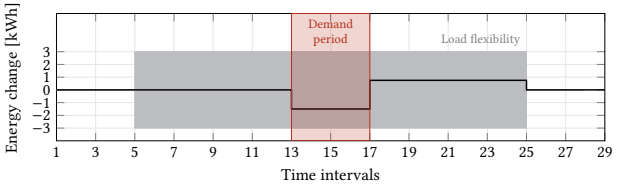

Figure 4: Results for the variant with zero total energy change and no adjustment period with $w_1 = 0.6$ and $w_2 = 0.4$.

their flexibility so that the costs, risks and energy fluctuations are all minimized. Since the objectives are scalarized with the weighted sum approach, correctly setting their weights is crucial for generating a set of diverse solutions representing various trade-offs between costs and risks.

By creating three scenario variants, we were able to explore the effect of some parameters on the optimization outcome. We observe that:

- Regardless of the variant, the optimal load schedule does not deviate from the forecast one if the importance of risk is too high, i.e., if the weight w_2 is too large. This critical value of w_2 depends on the scenario variant.
- If the consumer is obliged to a zero sum in load increase and reduction, the optimal solution uses the minimal necessary resources to earn a rebate while avoiding excessive energy changes.
- When the adjustment period is unspecified, the prosumer is less likely to increase the load just before the demand period.

Moving forward, we need to refine the objectives. The current method to assess the baseline consumption is susceptible to exploitation and should be amended. We could calculate the consumer baseline from similar consumers that do not participate in DR as suggested in [6]. We will also need to revise the penalty calculation to account for the imminent change of tariffs in the Slovenian energy market. We additionally plan to improve the calculation of risks to ensure more robust optimization and real-world applicability. Finally, we intend to develop a better strategy for setting the weights, targeting values with the most significant impact rather than evenly distributing them.

Abstract

The growing interest in hydrogen gas as a fuel drives research into environmentally friendly hydrogen production methods. One viable approach of obtaining hydrogen is the electrocatalysis of water, which includes the hydrogen evolution reaction (HER) as one of the half-reactions. In the search of highly active catalysts for the HER, machine learning can be effectively utilized to develop models for calculating hydrogen adsorption energy, a key descriptor of catalytic activity. In this study, we learned models for predicting hydrogen adsorption energy on platinum. We used various machine-learning (ML) techniques on two datasets, one for extended surfaces and the other for nanoparticles. The respective results reveal that ML models for extended surfaces are more accurate than those for nanoparticles, and that the features describing the local environment are the most significant for the predictions. For surfaces, the coordination number is the most relevant feature, while the d-band center is the most important for nanoparticles. The ML models developed in this study lack sufficient accuracy to provide reliable results, highlighting the need for further investigation with additional features or larger datasets.

Keywords

platinum, hydrogen, DFT calculations, decision trees, feature ranking

1 Introduction

A lot of scientific and societal interest is devoted to hydrogen fuel, which can generate electrical power by producing water as a byproduct. One environmentally friendly method of producing hydrogen is through the electrocatalysis of water, where hydrogen and oxygen gases are formed. This process involves two reactions: oxygen and hydrogen evolution reactions. Considerable effort is being directed towards improving catalysts for both reactions and understanding the fundamental processes involved [21, 13]. In this contribution, we will focus on the hydrogen evolution reaction (HER), for which platinum is known to be a highly active catalyst due to its near-optimal hydrogen adsorption free energy [15, 21]. However, the high cost of platinum motivates ongoing research of alternative materials.

The mechanism of HER includes adsorbed hydrogen atom (H*) as an intermediate. Consequently, the adsorption energy of hydrogen is often used as a descriptor of the catalytic activity of the material [15, 21]. The most straightforward approach to obtain the adsorption energies is with density-functional theory (DFT) calculations. However, as the size of the system and the number of different adsorption sites increase, a full DFT analysis becomes computationally unfeasible. To address this challenge, machine-learning methods can be employed to predict hydrogen adsorption energies based on DFT results, enabling the investigation of more complex systems [10]. For example, bimetallic nanoparticles were investigated by Jäger et al. [8] and Zhang et al. investigated amorphous systems [20].

This contribution focuses on the use of machine learning for predicting hydrogen adsorption energies on platinum using electronic and geometric descriptors. Two separate datasets were constructed, one for surfaces and the other for nanoparticles. By employing supervised learning and attribute ranking, we built ML models, assessed their accuracy and analyzed whether the two datasets exhibit similar correlations. The idea of the contribution is illustrated in Figure 1.

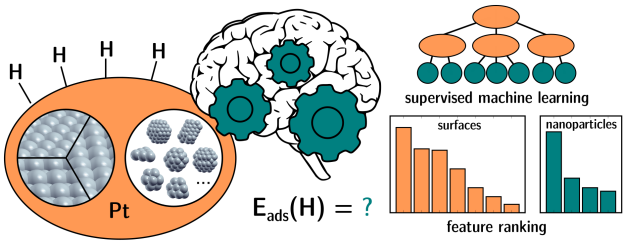

Figure 1: Supervised machine learning and feature ranking was performed for hydrogen adsorption energy on platinum catalysts modeled as surfaces and nanoparticles.

2 Materials and Methods

2.1 DFT Calculations and Datasets

We utilized DFT calculations to calculate hydrogen adsorption energies (a target variable for ML) and electronic descriptors for ML. We also utilized geometric descriptors. Two datasets were constructed, one for platinum nanoparticles and the other for platinum surfaces.

DFT calculations were performed with the Perdew-Burke-Ernzerhof (PBE) approximation [17], a plane-wave basis set, and PAW pseudopotentials [3]. Energy cutoffs were set to 50 and 575 Ry for wavefunctions and electron density,

respectively. Methfessel-Paxton smearing [12] of 0.02 eV was employed.

Pt(111), Pt(100), and Pt(110) surface slab models were constructed with the calculated lattice parameter of bulk Pt (3.97 Å). The models of Pt(111) and Pt(100) surfaces consist of 4 atomic layers, with the bottom layer fixed to bulk positions, while Pt(110) has 6 atomic layers with the bottom two layers fixed. To achieve a greater variety of adsorption sites, Pt(111) and Pt(100) were also modeled with a missing-row defect. All surface models are shown in Figure 2. Calculations accounted for the dipole correction and periodic images of slabs were separated by at least 15 Å of vacuum. Different sizes of surface supercells were used, and the k-point grid for (1×1) surface unit cells of Pt(111), Pt(100), and Pt(110) were 12×12×1, 11×11×1, and 11×8×1, respectively. For larger supercells, the number of k-points was adapted accordingly.

Calculations with nanoparticles were performed with the gamma k-point and Martyna-Tuckerman correction for isolated systems [11]. Nanoparticles were modeled with different shapes and sizes, consisting of 3 and up to 116 atoms. Their periodic images were separated by at least 15 Å of vacuum. All calculations were preformed with the Quantum ESPRESSO package [5].

The hydrogen adsorption energy was calculated as:

$$E_{\mathrm{ads}} = E_{\mathrm{H}*} - E_{*} - \frac{1}{2}E_{\mathrm{H_2}} \tag{1}$$

where $E_{\mathrm{H}*}$ is the calculated energy of optimized adsorption system, E_* is the energy of the standalone platinum system, and $E_{\mathrm{H_2}}$ is the energy of the hydrogen molecule. All performed calculations included only one adsorbed H atom per supercell or nanoparticle.

As an electronic descriptor, we used the d-band center, which is considered to be a good indicator of metal reactivity [6]. It was obtained through DFT calculations using the following equation:

$$\varepsilon_{\mathrm{d}} = \frac{\int_{-\infty}^{\infty} n_{\mathrm{d}}(E)EdE}{\int_{-\infty}^{\infty} n_{\mathrm{d}}(E)dE} \tag{2}$$

where E is the energy and n_{d} is the projected density of states on d-orbitals of the atoms forming the adsorption site.

For the geometric descriptors, we determined the average coordination number of Pt atoms forming the adsorption site, as well as the generalized coordination number (GCN) of the adsorption site [2], calculated as:

$$\mathrm{GCN}(i) = \sum_{j=1}^{N_i} \frac{\mathrm{CN}(j)}{\mathrm{CN}_{\mathrm{max}}} \tag{3}$$

where i denotes an atom or a group of atoms forming the adsorption site, N_i is the number of first nearest neighbors of i, which are denoted with j. $\mathrm{CN}(j)$ is the coordination number of atom j and $\mathrm{CN}_{\mathrm{max}}$ is the maximal coordination of a given site found in the bulk material.

In addition, the type of adsorption site was used as a descriptor. For extended surfaces, the coverage of H atoms, the surface area per H atom and surface type were also used for learning. For nanoparticles, some descriptors relevant to the size of nanoparticles were also utilized, in particular: the number of all atoms (N_{all}) in the nanoparticle, the number of surface atoms (N_{surf}), the maximal (r_{max}) and minimal (r_{min}) distances from the center of the nanoparticle to the surface atoms and the distance from the center of the nanoparticle to the adsorption site (r_{ads}). The datasets for surfaces and nanoparticles contained 46 and 85 data points, respectively.

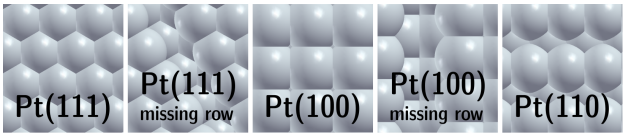

Figure 2: Models of extended surfaces used to calculate hydrogen adsorption energies.

2.2 Machine-Learning Methods

The prepared datasets were analyzed using the Weka software package [4]. The target value in both datasets is the hydrogen adsorption energy, making this a regression task. Supervised machine learning was employed to develop models for predicting the target value, which were evaluated by 10-fold cross-validation.

One of the used methods is linear regression, that computes the linear relationship between the target value and the descriptors. The relevant descriptors included in the equation were selected according to the M5 method [18]. This method iteratively removes descriptors with the smallest effect on the model until the error of the model no longer decreases.

We also used the random forest method [7, 1] with 100 trees of unlimited depth. With this method, multiple decision trees were constructed by selecting relevant features from a random subset of $\mathrm{int}(\log_2(m)+1)$ features, where m is the total number of features. The final values are the averages of the predictions from the individual trees.

To obtain an explainable ML model, we also built regression trees using the M5' method [18, 19]. In this method, trees are built by splitting the training sets according to attributes that maximize the standard deviation reduction. After the trees are constructed, they are pruned to avoid overfitting and smoothed to address discontinuities between the leaves. For our datasets, we used unpruned trees to prevent the formation of trees that are too small and give poor predictions. We also restricted tree branching to a minimum of 6 instances per leaf node for surfaces and 20 for nanoparticles to avoid overfitting the data and to ensure trees of sufficient size.

We also performed variable importance estimation and ranking for our selected descriptors with all data points used as a test set. To evaluate the importance of the descriptors with respect to hydrogen adsorption energy, we employed two methods: ReliefF [9] and correlation [16]. The ReliefF method is more sensitive to feature interactions and works by calculating the distances between training instances and identifying the 'nearest hit' and 'nearest miss'. It then adjusts the weights of the differing descriptors between the target and nearest instances. The correlation method evaluates the Pearson correlation coefficient [16]

between the features and the target variable, without accounting for interactions between features. It gives scores ranging from −1 to 1, with 1 being the highest correlation score, a score of −1 indicates anti-correlation, and 0 indicates no correlation.

3 Results and Discussion

3.1 Machine-Learning Models

Supervised machine learning was performed using linear regression, random forest, and M5' regression tree. The obtained Pearson's correlation coefficients and root mean squared errors (RMSE) between true and predicted values are shown in Table 1.

We can observe that not all ML models provide better RMSE values compared to those calculated with a simple arithmetic average, referred to as the default predictor. For surfaces, linear regression and random forest perform the best and yield similar results. The regression tree model performs the worst and has higher RMSE compared to the default predictor. For nanoparticles, all methods yield errors close to those of the default predictor and correlation coefficients bellow 0.5.

The obtained results indicate that with the selected descriptors, the hydrogen adsorption energies are more accurately predicted on surfaces, which are simpler as compared to nanoparticles. Surfaces have high symmetry and only a handful of different adsorption sites, while nanoparticles have different shapes and sizes, consist of different facets, and each nanoparticle has numerous different adsorption sites. This gives a huge variety of adsorption sites that can make the prediction of adsorption energies harder.

Considering the best models, the obtained adsorption energies have an error of ±0.13 eV for surfaces and ±0.22 eV for nanoparticles. Due to the exponential dependence of reaction rate and adsorption energy, even a small error in adsorption energy hugely affects the reaction rate. Hence, the models, particularly for nanoparticles, do not provide sufficiently accurate results for any practical use.

The selected ML models also provide insights into the relations between the considered features and the target variable. The linear regression model for nanoparticles includes only the d-band center and a factor for the hollow adsorption site, whereas the equation for surfaces is more complex. It includes adsorption site, surface type, and both coordination numbers. This indicates that for nanoparticles, the d-band center is the most relevant factor, while for surfaces, geometric factors exhibit greater predictive value.

Table 1: Pearson's correlation coefficients (CC) and root mean squared errors (RMSE) in eV units for all three used ML methods. For comparison, RMSE of the default predictor is also given.

	surfaces		Nanoparticles	
	CC	RMSE	CC	RMSE
linear regression	0.71	0.13	0.38	0.22
random forest	0.69	0.13	0.34	0.22
M5' decision tree	0.49	0.19	0.34	0.22
default predictor	/	0.18	/	0.23

The regression-tree models shown in Figure 3 have lower accuracy and, consequently, are less reliable.

The ML models could be improved by expanding the dataset or by calculating additional descriptors. For surfaces, more data can be obtained through calculations on a wider variety of surface types and by accounting for different surface defects. However, expanding the dataset for nanoparticles is limited by their size, since DFT calculations for larger particles are computationally too demanding. Therefore, a larger number of different smaller particles can be tested instead. Using more sophisticated descriptors such as atom-centered symmetry functions, smooth overlap of atomic positions and many body tensor representation could also improve the results, but would require different sampling of adsorption structures. The use of transfer learning from pre-trained models based on chemical structures could also lead to significant improvements.

3.2 Feature Ranking

Feature ranking was performed for both surfaces and nanoparticles, with the results presented in Figure 4. The ReliefF and correlation importance criteria provide different rankings of features. For surfaces, the coordination number is identified as the most relevant descriptor, followed by the generalized coordination number. In contrast, for nanoparticles, the d-band center is the most important descriptor. Features describing the size of different nanoparticles show lower relevance for predictions. The most relevant features in both data sets describe the local environment of the adsorption site, indicating the local nature of adsorption.

The importance of the d-band center is already well-documented in the literature [14], as it correlates with the reactivity of metals. As seen from the graphs, the d-band center is not so strongly correlated with the hydrogen binding energy on surfaces. This can be attributed to the fact that on a perfectly flat surface, all surface atoms have the same d-band center. In contrast, on nanoparticles, the d-band center varies for each adsorption site because the atoms are not equivalent. Therefore, the d-band center is expected to be more relevant for nanoparticles. For the ranking based on correlation, the calculated factors for the

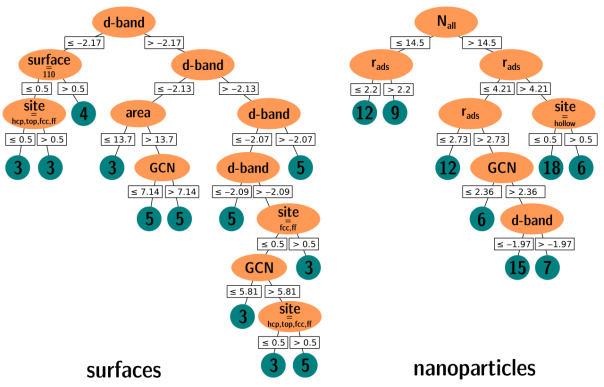

Figure 3: Schematic representation the obtained random-tree models for ideal surfaces and nanoparticles. Nodes are denoted with orange and the resulting classes are represented with turquoise circles and include the number of data points in the class.

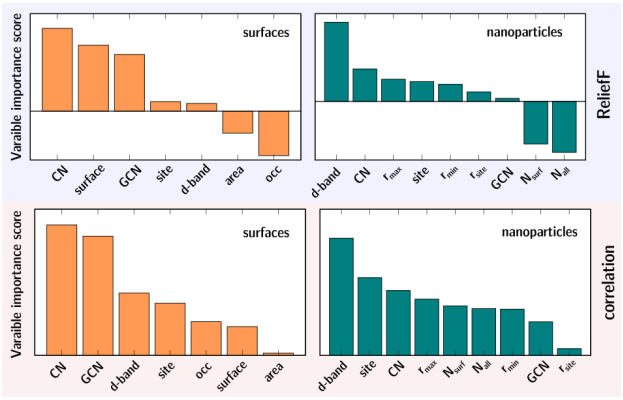

Figure 4: Variable importance scores calculated by the ReliefF and correlation criteria. Importance scores for correlation criteria are given as absolute values.

d-band center are negative. This indicates that a lower d-band center corresponds to a higher adsorption energy and consequently a less reactive site, which is physically intuitive.

It is also interesting to note that the surface type descriptor is not very relevant according to correlation, yet it becomes the second most important feature when other descriptor are considered. This can be attributed to the fact that this descriptor has the same value for all adsorption sites on the same surface. However, when combined with other descriptors, it can give additional information, as similar adsorption sites on different surfaces can yield considerably different adsorption energies.

4 Conclusion

We applied different ML techniques to predict the adsorption energy of hydrogen on platinum surfaces and nanoparticles using simple geometric and electronic descriptors. Models for predicting adsorption energy on surfaces performed better, with the linear regression and random forest methods showing the highest correlation coefficient and accuracy. In contrast, predictions for nanoparticles yielded lower correlation coefficients and accuracy similar to the one calculated by a default predictor. Therefore, the models presented in this contribution do not provide accurate estimation of hydrogen adsorption energies. Utilizing more sophisticated descriptors and larger training data sets could enhance the performance of these models.

Differences between datasets are also evident in feature ranking. For surfaces, coordination numbers are the most relevant descriptors, while for nanoparticles, the d-band center shows the highest relevance. All these relevant descriptors are related to the local environment of the adsorption site, indicating that adsorption is a local phenomenon.

Abstract

Non-communicable diseases (NCDs) have become a significant public health challenge in developed countries, driven by common risk factors such as obesity, low physical activity, and unhealthy lifestyle choices. Early childhood and adolescence are crucial for establishing healthy behaviours, and early intervention can play a crucial role in preventing or delaying the onset of NCDs later in life. However, current tools for identifying high-risk individuals are primarily designed for adults, which results in missed early detection opportunities in younger populations. The SmartCHANGE project (https://smart-change.eu/) seeks to bridge this gap by developing reliable AI tools that assess risk factors in children and adolescents as accurately as possible while promoting optimized risk reduction strategies.

In developing the risk assessment tool, we addressed the challenge of merging diverse datasets, predicting missing data to create longitudinal datasets, implementing existing validated models for diabetes (QxMD) and cardiovascular disease (SCORE2), and ultimately creating a simple online application to demonstrate the functionality of the developed risk tool.

Keywords

risk tool, dataset merge, neural networks, online application

1 Introduction

In developed countries, non-communicable chronic diseases (NCDs) have emerged as the foremost public health challenge over recent decades. According to the World Health Organization (WHO), NCDs account for more than 70% of mortality in the European region [18]. Common risk factors for NCD include obesity, poor physical fitness, and unhealthy lifestyle habits such as inadequate physical activity, sedentary behaviour, poor nutrition, insufficient sleep, smoking, and excessive alcohol consumption. Embracing a healthy lifestyle can improve physical, social, and mental well-being, especially among youth, while mitigating the risks of NCD-related morbidity and mortality [15], [14], [5].

Traditionally, clinical prevention strategies for NCDs have been directed at adults, as the risk factors typically become evident in adulthood. However, recent evidence suggests that focusing interventions on children and adolescents can be a more effective strategy for reducing NCD risk through behaviour modification [13]. While NCDs may not appear in childhood or adolescence, early signs can alreadexistnt. Tackling risk factors and promoting healthy habits during these stages can prevent or delay NCDs later in life [12]. Childhood and youth are also crucial periods for establishing healthy lifestyle habits. Since risk factors for NCDs often persist from childhood into adulthood [9], early risk assessment and reduction of risk factors can potentially lower the incidence of NCD. Lastly, NCDs in youth are a significant global health challenge, with nearly one in five adolescents worldwide being overweight or obese [1].

Identifying high-risk individuals for future health problems is essential for targeted preventive interventions. Existing tools focus mainly on adults [6], for instance predicting 10-year risk of developing cardiovascular disseased [17] or diabetes [8], missing the opportunity to identify high-risk individuals during childhood and adolescence, a critical period for forming lifestyle habits. However, recognition of health risks is not a trivial task. For instance, only 35% of doctors in the UK are aware of the recommendations for physical activity, and only 13% can specify the recommended weekly duration. Moreover, more than 80% of parents of inactive children incorrectly believe that their children are sufficiently active [4]. Developing risk prediction tools for children and youth would significantly improve NCD prevention and promote cost-effective strategies.

This paper presents the development of an initial demo application of a risk assessment tool designed for children and adolescents in the SmartCHANGE project [3] - merging datasets, predicting missing data to build longitudinal datasets, and implementing existing validated models for diabetes (QxMD) and cardiovascular disease (SCORE2) and finally, the application development.

Table 1: Overview of Selected Datasets

Dataset Name	SLOfit	LGS	YFS	AFINA-TE
Country of Origin	SI	BE	FI	PT
Age Range	5 - 20	5 - 25	0 - 60	5 - 25
Longitudinal Study	Yes	Yes	Yes	No
# of Participants	280,165	17,991	3,596	1,632
# of Measurements	3,121,399	31,127	32,364	1,632
# of Variables	13	80	24	59
% of Missing Values	2.55%	16.25%	39.49%	33.53%

2 Methodology

2.1 Datasets

To estimate the risk of non-communicable diseases in children, ideally, one would need a dataset that tracks risk factors from a young age (when the prediction is made) to an older age (when these diseases typically emerge). Such comprehensive longitudinal datasets would allow for accurate predictions of an individual's likelihood of developing a disease later in life based on their early risk factors. However, such datasets are currently unavailable, so we must rely on a collection of partial and often heterogeneous datasets.

In our study, we have chosen 16 types of variables that are used by risk models SCORE2 [17] and QxMD [8]. The datasets we were using are described in Table 1. The SLOfit program is a school fitness monitoring initiative in Slovenia [11]. The Leuven Growth Study (LGS)[2, 16] is a longitudinal study initiated in 1969 that evaluates physical fitness. The Cardiovascular Risk in Young Finns Study (YFS)[10], started in the late 1970s, focuses on early cardiovascular disease risk factors. The AFINA-TE dataset [7] is part of an intervention program in Portugal designed to enhance physical fitness, activity, and nutritional knowledge among children and adolescents.

2.2 Data Imputation Through Datasets

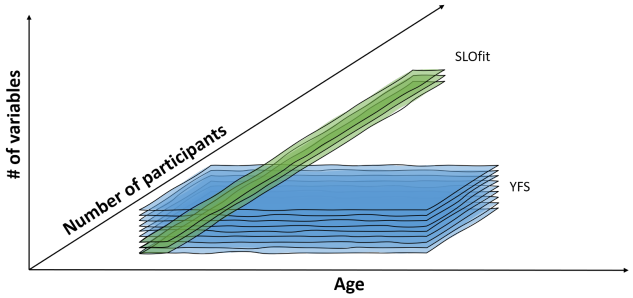
The first step involved imputing missing values within each dataset (see Figure 1 for representation). To guide this process, we calculated the coverage for each variable. Initially, we used only fully observed variables—such as height, weight, and sex—as features in models to impute missing values for other variables. The variables were imputed based on their coverage using machine learning on existing features. After this initial imputation sweep, we had a complete, though potentially imperfect, dataset. In the second sweep, we treated all columns as complete, incorporating the newly imputed values from the first sweep. This allowed us to train models with a more comprehensive dataset, improving the accuracy of the imputation.

2.3 Longitudinal Data Imputation

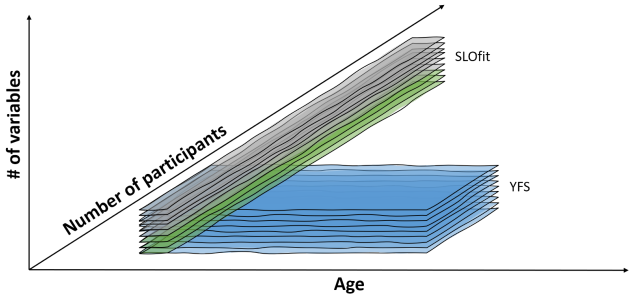
In the second step, we employed a similar approach but focused on merging the datasets to fill the new merged dataset longitudinally (see Figure 2 for representation). To maximize their overlap, we treated certain variables as equivalent—such as vertical jump from the LGS dataset and standing long jump from the SLOfit dataset.

Since the raw values of these variables differ, we standardized them by converting them to z-scores, which were calculated as follows:

$$z_score = \frac{variable - mean}{standard_deviation}.$$



(a) Example of the datasets pre-imputation.



(b) Example of the datasets post-imputation.

Figure 1: The YFS dataset (blue) covers a broad range of variables across a wide age span but includes a relatively small number of participants. In contrast, the SLOfit dataset (green) has many participants but includes fewer variables over a shorter age span. In the first step, we imputed the missing variables across the datasets (grey).

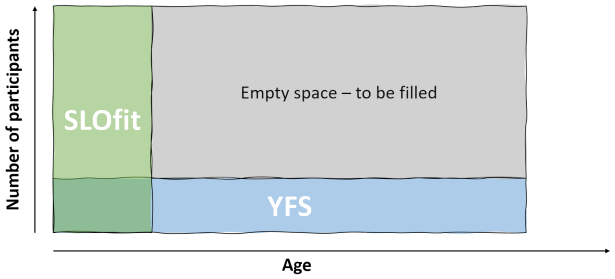


Figure 2: Longitudinal filling of the datasets.

For instance, a vertical jump one standard deviation above the mean in the LGS dataset was considered equivalent to a standing long jump one standard deviation above the mean in the SLOfit dataset. After matching and standardizing the columns across datasets, we merged the individual datasets into a single, comprehensive dataset and repeated the imputation process.

With a merged dataset free of missing values, we built models to predict attribute values at age 55—the oldest age supported by our data—using values from age 14. Due to the lack of data covering the entire age range from 14 to 55, we approached this in two stages: predicting from age 14 to 18 and then from 18 to

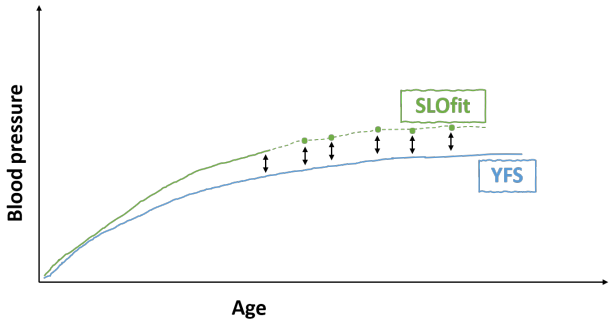

Figure 3: Population-based approach using z-scores.

55. The models used were simple neural networks with a single hidden layer.

This individual forecasting approach required available data for the same person from the start to the end age. However, since we had more data available for different people of various ages, we also explored a population-based approach to forecast the typical evolution of each variable. While this method is less personalized, it is also less prone to anomalies caused by atypical individuals. In the population-based approach, we again used z-scores, assuming that each person's z-score remains constant. For example, if someone's blood pressure is one standard deviation below the mean at age 14, it is assumed to stay one standard deviation below the mean at age 55 (see Figure 3).

2.4 Risk Models

The SCORE2 and QxMD models were used in the application to assess cardiovascular disease and type 2 diabetes risk. These models were chosen for their validity, robustness and effectiveness in predicting these chronic conditions. By incorporating both, healthcare practitioners can comprehensively evaluate cardiometabolic risk factors, aiding in well-informed patient management and intervention decisions.

The SCORE2 model, developed by the European Society of Cardiology, estimates the risk of cardiovascular events over ten years. It calculates the risk score by incorporating variables such as age, sex, smoking status, blood pressure, and lipid profile. Additionally, SCORE2 considers regional variations in risk factors, providing more accurate predictions tailored to specific populations [17].

The QxMD Diabetes Risk Calculator, a comprehensive clinical decision support tool, is employed to evaluate the risk of developing type 2 diabetes mellitus. This model integrates risk factors, including age, BMI, family history, physical activity level, and dietary habits, to estimate an individual's diabetes risk [8].

3 Evaluation

Table 2 presents the cross-validated evaluation results of our forecasting models. As anticipated, the errors in the first stage of individual forecasting are shallow due to the relatively short period. The emistakesin the second stage are higher but still considered acceptable, with the notable exceptions of weight and smoking. We hypothesize that the high variability during puberty, which many adolescents experience around age 14, complicates accurate weight forecasting. In population forecasting, the errors are generally more significant, which aligns with the less personalized nature of this method. However, weight is forecasted

	Ind. 18	Ind. 55	Pop.
Height [cm]	3.11	3.47	1.62
Weight [kg]	4.79	13.60	10.58
SBP [mmHg]	1.46	2.39	10.91
Total cholesterol [mmol/L]	0.05	0.10	0.64
HDL [mmol/L]	0.02	0.08	0.21
LDL [mmol/L]	0.05	0.17	0.51
Smoking [1-9]	1.01	1.72	2.26

Table 2: Mean absolute error for individual forecasting to ages 18 and 55, and for population forecasting.

with greater accuracy in this approach. In the future, we may explore combining both methods or select the more accurate one depending on the variable.

4 Demo Application

To show the general idea of the project, we constructed a demo application implemented with Python in the Dash framework. In the app, a user can specify the inputs (some inputs, such as steroid use, were fixed to make the app more concise) to the models, which in turn yielded two plots which showed how the cardiovascular and diabetes risk evolved from the currently selected age up to an age of an older adult, at age 55. In a different plot, we also showed how a risk factor chosen changes over time.

4.1 Risk Prediction using Demo Application

The developed demo application interface offers a dynamic tool for visualizing health risks based on various user-input parameters used in risk models (Figure 4). By allowing users to adjust these parameters, the dashboard generates real-time projections of two key risk metrics: a 10-year cardiovascular risk score and a 10-year risk of developing diabetes. These risks are shown in two line graphs, illustrating how these conditions' probability evolves with age. Additionally, the dashboard includes a feature that tracks the progression of a selected health parameter (BMI, systolic blood pressure, total cholesterol, HDL) over time, providing insight into how this factor might change as the individual ages. The developed tool intuitively explains how lifestyle and physiological factors contribute to long-term health risks, offering valuable insights for clinical decision-making and personal health management.

4.2 Further Development of the Application

The current version of the demo application is developed based on the data and models currently available. However, there remains an open question regarding the specific needs and preferences of the medical experts who will ultimately use the final application. To address this, we plan to present the current version to these experts and, based on their feedback, refine and enhance the application in subsequent iterations.

5 Conclusion

The SmartCHANGE project represents a significant step toward improving the early detection and prevention of non-communicable diseases (NCDs) in children and youth. While the tool presented in this paper is a demo version demonstrating some basic functionalities, our future work will focus on developing a more comprehensive web application for medical professionals and a mobile application for families. We also plan to enhance the tool

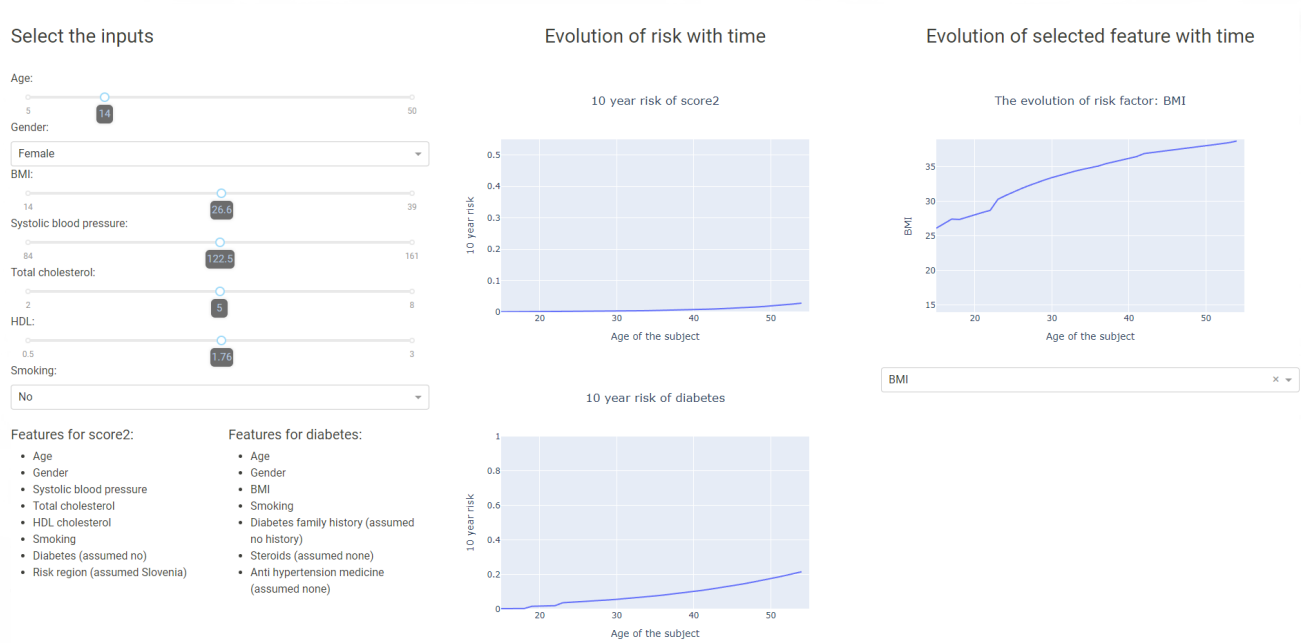

Figure 4: The figure is a dashboard interface that allows users to input various health-related parameters and observe the evolution of associated risks over time.

by replacing the current SCORE2 and QxMD risk models with more advanced models—Test2Prevent for diabetes and Healthy Heart Score for cardiovascular disease—incorporating features related to diet and physical activity. Additionally, the application will be updated to meet medical experts' needs based on their feedback.

Abstract

Empathy is a multifaceted concept with both cognitive and emotional components that plays a crucial role in social interactions, prosocial behavior, and mental health. In our study, empathy and general arousal were induced via VR, with physiological signals measured and ground truth collected through questionnaires. Data from over 100 participants were collected and analyzed using multiple machine learning models and classification algorithms to predict empathy based on physiological responses. We explored different data balancing techniques and labeled data in multiple ways to enhance model performance. Our results show that they are effective in detecting general arousal, empathy, and differentiating between non-empathic and empathic arousal, but the models encountered difficulties with precise emotion detection. The dataset extracted at 5-second intervals and models using Random Forest and Extreme Gradient Boosting showed the best performance. Future work will focus on refining emotion detection through advanced modeling techniques and investigating gender differences in empathy.

Keywords

VR, mental states, machine learning, sensor data

1 Introduction

Empathy is a multifaceted concept explored across various fields, including psychology, neuroscience, and sociology. Though no universal definition exists, empathy is generally understood to include both cognitive (understanding another's perspective) and emotional (experiencing another's feelings) components [8]. Our research defines empathy as the ability to model others' emotional states and respond sensitively while recognizing the self-other distinction [14].

There is no "golden standard" for measuring empathy [10], with methods varying from self-report questionnaires to psychophysiological measures like heart rate and skin conductance. Each method has its pros and cons, often leading to a combination of approaches for a comprehensive assessment. Psychophysiological measures offer objective data but face challenges due to individual variability and non-empathetic factors. Our study addresses these issues by using machine learning to directly measure empathy from physiological signals, offering a novel approach.

VR creates an immersive environment that enhances empathy by allowing users to experience different perspectives and engage emotionally. VR is effective for empathy training and is referred to as 'the ultimate empathy machine' [1, 11] for various reasons: 1) Immersive Experience: Provides a strong sense of presence, helping users adopt new viewpoints [15]. 2) Perspective-Taking and Emotional Engagement: Simulates realistic scenarios to provoke emotional responses and understanding [19]. 3) Empathy Training: Effective in healthcare, education, and diversity training by challenging preconceptions and deepening emotional insights [16]. 4) Ethical Considerations: Ensures respectful use of VR, balancing immersive experiences with participants' well-being [2].

The objective of this study was to examine how participants' empathy correlates with changes in their physiological metrics, measured using sensors such as inertial measurement unit (IMU), photoplethysmograph (PPG), and electromyography (EMG). Participants were immersed in 360° VR videos featuring actors displaying various emotions (sadness, happiness, anger, and anxiety) and reported their empathetic experiences via brief questionnaires. Using data from these sensors and questionnaires, machine learning models were developed to predict empathy scores based on physiological responses during the VR sessions [9].

2 Materials and Data Collection Process

2.1 Materials and Setup for Empathy Elicitation in VR

To elicit empathy, we immersed participants in a 360° and 3D virtual environment, as VR has proven more effective than methods like 2D videos, workshops, or text-based exercises [8, 13, 17, 20]. We used videos featuring actors expressing four emotions—happiness, sadness, anger, and anxiousness—without additional content to avoid confounding factors [2]. Recognizing the impact of understanding emotional context, an audio narrative version was also created, followed by a corresponding video (50-120 seconds). To ensure gender balance, we recorded videos with two male and two female actors. Five versions were developed: four with narratives (two male, two female) and one non-narrative, where all emotions are portrayed by all actors without accompanying narratives. The non-narrative version allows gradual transitions between emotions, making it suitable for participants of all linguistic backgrounds.

Additionally, a 2-minute forest video ("The Amsterdam Forest in Springtime") was included at the start to establish a relaxed baseline and a roller coaster video ("Official 360 POV - Yukon Striker - Canada's Wonderland") at the end to control for non-empathic arousal. Both videos were sourced from YouTube.

Participants completed trait empathy questionnaires (QCAE) [14] and, after each emotion-specific video, provided feedback

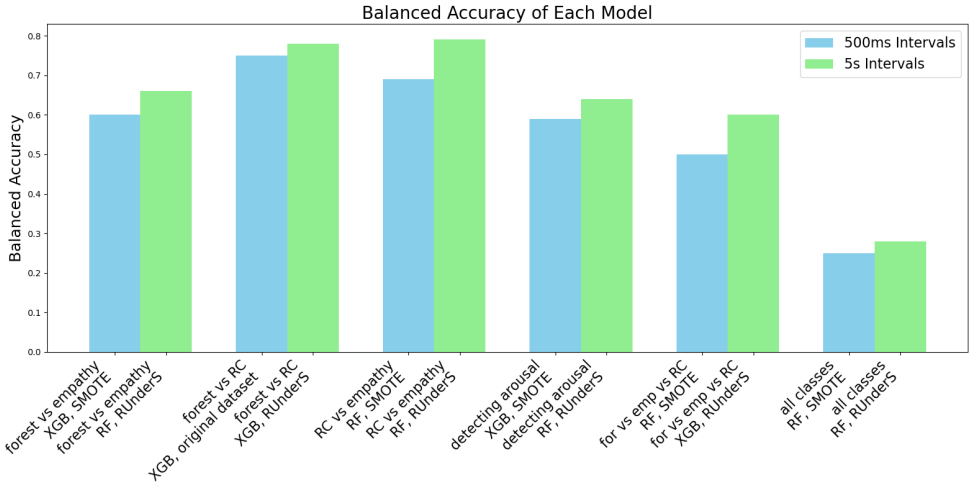

Figure 1: The best accuracies for each group of models, developed using datasets extracted at two different frequencies and various data balancing techniques, presented for all the labeling schemes

on their empathic state (State Empathy Scale) [18], arousal and valence levels (SAM) [3], and personal distress (IRI) [5]. Each VR session lasted around 20 minutes to minimize VR sickness, with participants viewing one of five versions.

Sensor data were collected using the emteqPRO system attached to the Pico Neo 3 Pro Eye VR headset, including EMG for facial muscle activation, PPG for heart rate, and IMU for head motion tracking. The device uses an internal clock as well [12].

2.2 Dataset Description

In this research, we used convenience sampling to recruit participants from the general public without a specific selection pattern. Participants were invited from various sources, including Jožef Stefan Institute employees, university students, and the general public. Invitations were sent verbally or in writing. Data collection concluded with 105 participants, averaging 22.43 ± 5.31 years (range 19–45), with 75.24% identifying as female. Participants had diverse educational and professional backgrounds. Additionally, ethical clearance for this study was obtained from the Research Ethics Committee at the Faculty of Arts, University of Maribor, Slovenia (No. 038-11-146/2023/13FFUM). Furthermore, written informed consent was obtained from the actors prior to recording.

The EmteqPRO system not only provides raw sensor data but also generates derived variables through the Emteq Emotion AI Engine, which utilizes data-fusion and machine learning to analyze multimodal sensor data and assess the user's emotional state. This system provides a file with 29 derived features, called affective insights for each recording: 7 features for heart-rate variability (HRV) and 3 for breathing rate; 2 features for facial expressions; 4 features for arousal and 4 for valence; 1 feature for facial activation; and 1 feature for facial valence. Additionally, head activity is tracked, reflecting the percentage of the session with head movement. Dry EMG electrodes on facial muscles such as the zygomatic, corrugator, frontalis, and orbicularis provide four more features, each representing muscle activation as a percentage of maximum activation observed during calibration. The data also includes the time elapsed since the start of the recording and the row index.

3 Methodology

3.1 Preprocessing

Since all the features or insights are numeric, except for the feature "Expression/Type," which has three values—smile, frown, and neutral—we applied one-hot encoding, a technique used in data preprocessing where categorical (non-numeric) variables are transformed into a numerical format. Each unique value in the original non-numeric feature is transformed into a separate binary (0 or 1) feature.

Next, because missing values represent less than 1% of the total data for each participant, they were filled in using the average of each feature's values. Scaling the values in the descriptive features between 0 and 1 was the final step in the preprocessing process.

3.2 Feature Engineering

Since features were provided at intervals ranging from 1 second to 500 milliseconds, we divided the data into two windows: one of 5 seconds and one of 500 milliseconds. For each window, we computed features from the 22 insights across the seven modules, as well as from the features for head activity and facial muscle electrodes, deriving a total of 108 new features, including minimum, maximum, average, and standard deviation for each original feature or insight. Additionally, the features for head activity and facial muscle electrodes were used to define 'Expression/Type,' and the time and row index were used as provided. However, the row index was disregarded further in the study.

We labeled the dataset in six different ways: 1) as a binary classification aiming to detect empathic arousal, comparing empathic parts with the forest part of the video, while excluding the non-empathic content of the roller coaster video; 2) as a binary classification using the forest and roller coaster, aiming to detect non-empathic arousal; 3) again, as a binary classification, but including only empathic parts and the roller coaster, aiming to distinguish between empathic and non-empathic arousal, and examining the differences in physiological responses between empathic content and non-empathic arousal-inducing content, such as the roller coaster video; 4) aiming to detect arousal in

general, regardless of whether it is empathic or non-empathic, by splitting the entire dataset into two classes: the forest and everything else, including empathic parts and the roller coaster; 5) into three classes: treating the chunks of the roller coaster and forest as separate classes and grouping all the empathic parts into one class, without differentiating between the different emotions. The goal is to distinguish among no-arousal, empathic arousal, and non-empathic arousal; 6) with the average of participants' answers to the state empathy questions for each part of the video, with each part of the empathic content considered a separate chunk. Additionally, there are two other classes: the forest and the roller coaster. The aim is to detect the level of empathy participants experience during the session. We also included each participant's ID, intending to later use it for model evaluation with the 'leave-one-subject-out' technique.

4 Experiments and Results

4.1 Experimental setup

To build models for predicting a participant's state empathy during the VR session, we used six different classification algorithms: Gaussian Naive Bayes, Stochastic Gradient Descent Classifier, K-Nearest Neighbors Classifier, Decision Tree Classifier, Random Forest Classifier, and Extreme Gradient Boosting Classifier. The balanced accuracy score was used as an evaluation metric to assess the classification models for predicting participants' state empathy. This metric evaluates the overall balanced accuracy of the model by calculating the average of recall obtained on each class. Additionally, we used a confusion matrices to evaluate the performance of the classification models by comparing the actual and predicted labels.

For model evaluation, we used a Leave-One-Subject-Out cross-validation setup, where each subject is a unique participant identified by their ID.

Because the labeling schemes 2, 3, 5, and 6 are not balanced (with the 80% of the majority class), we conducted four experiments for each developed model: 1) applying the Synthetic Minority Over-sampling Technique (SMOTE) to create synthetic samples for the minority class to balance the dataset; 2) using the RandomUnderSampler (RUnderS) method to randomly select samples from the majority class, thereby reducing their count and balancing the dataset; 3) using SMOTETomek, a combination of SMOTE for oversampling and Tomek links for undersampling, which targets both the minority and majority classes; and 4) using the dataset as it is, without any undersampling or oversampling.

4.2 Results

Including models developed by six different classification algorithms on two distinct datasets—with two different window sizes—and utilizing four different data balancing techniques: undersampling, oversampling, combination techniques, and the dataset in its original form, along with six different labeling schemes, we obtained 288 unique confusion matrices and corresponding accuracies for each combination.

We ran a correlation matrix, which revealed that the highest correlation with the state empathy feature was found with the derived maximum and minimum values from the mean heart rate, the derived maximum and minimum values from the arousal class feature, and the average of the arousal class — the insight, which can be -1 (low), 0 (medium), or 1 (high). The derived standard deviation, maximum, and minimum values from the activation—expressed as a percentage of the maximum activation of particular muscles from the calibration session, especially the zygomaticus and orbicularis muscles—were also highly correlated.

Regarding the labeling schemes, we can conclude the following: 1) We can detect empathic arousal with confusion matrices that show a relatively good distribution of correct predictions across both classes and high accuracies for most of the developed models; 2) We can detect non-empathic arousal, with almost every developed model achieving a balanced accuracy higher than 60%, reaching up to 78%, and a reasonable balance between classes, indicating satisfactory classification performance; 3) We can even distinguish between empathic and non-empathic arousal with balanced accuracy of 79%; 4) We can detect arousal in general, again with high accuracies and balanced classes; 5) We can distinguish to some extent among no-arousal, empathic arousal, and non-empathic arousal; 6) However, it is currently very challenging to detect the precise level of empathy participants are feeling during the session using these methods, and to determine whether they are empathizing by mirroring emotions or experiencing something different while observing specific emotions. The best we can detect in this regard is up to 28% balanced accuracy, with confusion matrices showing a relatively balanced performance across multiple classes, with a good number of correct classifications, particularly in the more frequent classes.

Regarding the two window sizes, both models showed similar class balance and balanced accuracy scores. However, the dataset extracted at 5-second intervals performed slightly better. Using this dataset, false positives and false negatives were reduced more effectively. This led to more reliable classification performance, especially in terms of precision and recall, despite the smaller scale. Thus, the models developed using the 5-second interval dataset generally performed better, showing more effective classification and fewer errors. The simpler confusion matrix and potentially better handling of fewer classes suggest that it performs better in practical terms (Figure 2, Figure 1).

Regarding the data balancing techniques, the undersampling technique never produced the best results. For the dataset extracted at 500 ms intervals, using the SMOTE oversampling technique and SMOTETomek yielded the best results. For the dataset extracted at 5-second intervals, using the entire dataset yielded the best results, although models developed using SMOTETomek yielded slightly lower results in each combination of different labeling schemes.

Regarding the classification algorithms, Gaussian Naive Bayes performed the worst in terms of balanced confusion matrices, while Random Forest Classifier and Extreme Gradient Boosting performed the best across all combinations, with Random Forest Classifier showing slightly better results for most combinations (Figure 2, Figure 1).

4.3 Conclusion

In this study, we define the entire plan for developing materials, methods, and environments to evoke and measure the level of empathy. We started by defining the videos and the session, creating or selecting questionnaires for later use as ground truth, writing the narratives, recording the VR videos, and then editing and preparing them for use. Additionally, we collected a dataset from over 100 participants, which we filtered, preprocessed, and prepared for feature engineering and analysis.

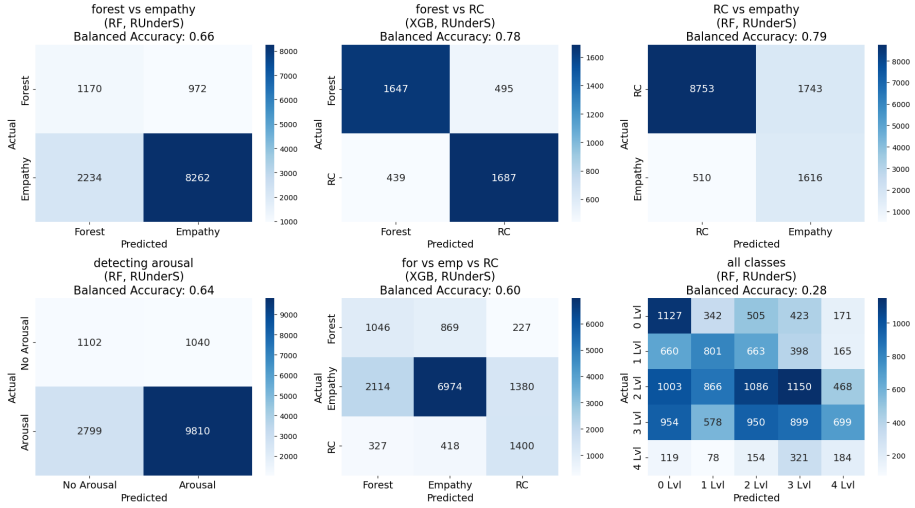

Figure 2: The best confusion matrices for each group of models, developed using dataset extracted at a 5s window size and various data balancing techniques, shown for all labeling schemes

We conducted and analysed four groups of experiments, totaling 288 combinations, where we developed models using two different window sizes, six classification algorithms, and three resampling techniques, with six different labeling schemes aimed at detecting various aspects of the dataset chunks: four empathetic parts, forest, and roller coaster.

The main conclusion is that we can detect arousal in general, non-empathic arousal, empathy, and differentiate between non-empathic and empathic arousal, as well as between relaxed states and arousal. However, we face difficulties in detecting and distinguishing between the precise levels of empathy during VR sessions using these methods and approaches.

Our next steps involve refining the detection of empathy levels during VR sessions by applying detailed data filtering and transforming it into a stationary format. Furthermore, we will develop models such as Autoregressive, Moving Average, and Extended Recurrent Moving Average, and use clustering techniques like DBSCAN and HDBSCAN. Additionally, we will extract more features from the raw data or use end-to-end neural networks. We plan to analyze gender differences in empathy with a t-test [7], and explore the impact of narrative context and emotions on empathic responses using ANOVA and MANOVA [4, 6].

Abstract

Microsatellite instability (MSI) is a crucial biomarker in colorectal cancer, guiding personalised treatment strategies. The focus of our paper is on evaluating how different state-of-the-art pretrained artificial intelligence models perform in extracting features on molecular and cellular oncology (MCO) study dataset to predict biomarkers. In this study, we present an advanced approach for MSI prediction using multiple instance learning on whole slide images. Our process begins with comprehensive preprocessing of WSIs, followed by tessellation, which breaks down large images into manageable tiles. State-of-the-art feature extraction techniques are utilised on these selected tiles, employing pretrained models to capture rich, discriminative features. Various aggregation methods are applied to combine these features, leading to the prediction of MSI status across the entire slide. We assess the performance of different pretrained models within this framework, demonstrating their effectiveness in accurately predicting MSI, with results showing an AUROC of 0.91 on the MCO dataset. Our findings underscore the potential of multiple instance learning-based approaches in enhancing biomarker prediction in colorectal cancer, contributing to more targeted and effective treatment strategies.

Keywords

multiple instance learning, whole slide images, colorectal cancer, biomarker prediction

1 Introduction

MSI is a crucial biomarker in colorectal cancer (CRC) that indicates defects in the DNA mismatch repair system, leading to a high mutation rate within tumor cells. MSI status has significant clinical implications, influencing treatment decisions, particularly the use of immunotherapy, and providing prognostic information. Traditionally, MSI is determined through laboratory tests such as PCR-based assays or immunohistochemistry (IHC) on tumor tissue samples, which require invasive biopsy procedures. However, these methods can be time-consuming, costly, and dependent on the availability of sufficient tissue samples.

Deep learning methods have emerged as a promising non-invasive alternative for MSI prediction by analysing whole slide images (WSIs) of histopathological samples. These models can detect patterns linked to MSI, eliminating the need for genetic testing. WSIs provide a comprehensive view of tumor histology, offering a faster, less invasive, and more accessible means of diagnosis.

Integrating deep learning into clinical practice can improve early MSI detection, personalise treatment, and reduce invasive procedures. WSI-based methods streamline diagnostics and enhance cancer care with accessible predictive analytics.

To manage these challenges, WSIs are often divided into smaller regions or patches. A common method to address these issues is Multiple Instance Learning (MIL) [3, 8]. Due to the vast size of WSIs, computational resources can be easily overwhelmed, making MIL an essential approach. MIL is a machine learning technique that operates on sets or "bags" of instances, where the label is assigned to the entire bag rather than individual instances. This is particularly advantageous in WSI analysis, where labels such as MSI status apply to the entire slide, which is composed of numerous smaller regions or patches.

In this context, [4] demonstrates state-of-the-art (SOTA) results in predicting MSI in colorectal cancer. Their workflow utilizes the Swin-T model on small datasets to predict MSI. First, a pretrained tissue classification model is employed to filter out non-tissue patches, followed by fine-tuning a pretrained model to classify the remaining patches. Both intra-cohort and external validation are performed. When trained on the MCO dataset (N=1065), the model achieved a mean AUROC of 0.92 ± 0.05 for MSI prediction. Similarly, [11] employs a transformer-based approach for large-scale multi-cohort evaluation, involving over 13,000 patients for biomarker prediction, achieving a negative predictive value of over 0.99 for MSI prediction. When trained and tested only on a single cohort (MCO), the model achieved an AUROC of 0.85. While [4] achieved promising results on the MCO dataset using an additional tissue classifier, we obtained comparable performance without the need for tissue classification. On the other hand, [11] used a multicentric cohort, which demands additional computational resources. In comparison to their results on the MCO dataset, we achieved a 6% improvement using a smaller dataset.

In this study, we leverage MIL to process WSIs for the prediction of MSI in CRC. By testing SOTA models on the MCO dataset, we aim to assess their performance in MSI prediction using MIL. This approach not only highlights the potential of MIL in processing complex, unannotated WSIs but also contributes

to the broader goal of improving biomarker prediction in CRC, ultimately supporting more personalized and effective treatment strategies.

The paper is organised as follows: Section 2 outlines the methods used in the pipeline, Section 3 provides a description of the data, Section 4 presents the results, and Section 5 discusses the findings and potential directions for future work.

2 Methods

This section outlines the pipeline for MSI prediction, as illustrated in Figure 1. The process begins with the preprocessing of WSIs, including tessellation into smaller patches. Next, SOTA pretrained models are employed to extract features from these patches. These models, trained on large and diverse datasets, capture rich and discriminative features crucial for accurate MSI prediction. Finally, aggregation techniques are applied to combine the information from the patches, enabling precise MSI status prediction for the entire slide. Each subsection provides a concise explanation of these individual processes.

2.1 Preprocessing

WSIs are first tessellated into smaller, more manageable patches to facilitate further processing. This step involves dividing the large images into smaller regions using the tiatoolbox presented in [9]. Non-informative tissue patches are removed to ensure the analysis focuses solely on relevant tissue areas.

Specifically, patches that are out of bounds—where only a portion contains actual image data and the remainder consists of padding—are discarded. Patches that consist entirely of tissue are retained for subsequent analysis. This preprocessing step ensures that only informative and relevant patches are used for feature extraction and MSI prediction.

2.2 Feature Extraction Methods

Since only WSI-level annotations are available, several pretrained feature extraction models - UNI [1], ProvGigaPath [13], Phikon [2] and CTransPath [12] - are applied to patches, removing the need for detailed patch-level labeling. These SOTA models, trained on large datasets, can capture complex and discriminative features essential for accurate biomarker prediction. The extracted feature embeddings are then used as input for the aggregation and classification stages, laying the foundation for precise MSI status prediction. For technical details about these models, see Table 1.

2.3 Aggregation Methods

After feature extraction, we apply aggregation techniques to combine patch-level features into a slide-level representation. Traditional pooling methods like max-pooling and mean-pooling provide straightforward approaches.

However, these methods are limited by their lack of trainability. In recent years, attention-based pooling or ABMIL became a popular technique that adresses this issue [6]. ABMIL assigns a weight α_i to each patch's feature vector, reflecting its importance:

$$F = \sum_{i \in P} \alpha_i f_i$$

The attention scores α_i are computed as:

$$\alpha_i = \frac{\exp(w^\top \tanh(V f_i))}{\sum_{k \in P} \exp(w^\top \tanh(V f_k))}$$

where w and V are trainable parameters.

This approach allows the model to dynamically focus on the most relevant patches, leading to more accurate MSI predictions.

Another technique similiar to attention is DSMIL [7] or a dual stream aggregator, consisting of two branches, employing both an instance classifier and a bag classifier. Let $h_i \in \mathbb{R}^{L \times 1}$ be a feature embedding, and $B = \{h_0, ..., h_n\}$ a bag of embeddings. The first stream uses an instance classifier, followed by a max-pooling operation to obtain a score $c_m(B)$ and the critical embedding h_m. The second stream aggregates the embeddings into a single bag embedding which is then passed through a bag classifier:

$$c_b(B) = W_b \sum_{i}^{n-1} U(h_i, h_m) v_i$$

Where W_b is a weight vector for classification, v_i an information vector and U is a distance measurement between an arbitrary embedding and the critical embedding:

$$U(h_i, h_m) = \frac{\exp(\langle q_i, q_m \rangle)}{\sum_{k=0}^{n=1} \exp(\langle q_k, q_m \rangle)}$$

where is a query vector. Both q_i and v_i are calculated by:

$$q_i = W_q h_i, \quad v_i = W_v h_i, \quad i = 0, ..., n-1$$

where W_q and W_v are weight matrices. The final prediction is given by:

$$c(B) = \frac{1}{2}(c_m(B) + c_b(B))$$

The last approach for feature aggregation reviewed in this paper is TransMIL, as proposed in [10], a Transformer based aggregation method, which unlike the afore-mentioned methods, takes into account spatial information as well. By treating a bag of embeddings as a sequence of tokens, TransMIL uses a novel TPT module made up of two Transformer layers and a position encoding layer, where Transformer layers are designed for aggregating morphological information and Pyramid Position Encoding Generator (PPEG) which encodes spatial information, followed by a multi-layer perceptron (MLP) which classifies the bag.

2.4 MSI Classification

The aggregation step produces a single feature vector F, which encapsulates the most informative characteristics of the entire slide. This aggregated feature vector F is then passed through one or more fully connected (dense) layers. These layers apply learned weights and biases to the features to transform them into a form that is more suitable for classification. The output of the fully connected layer is often passed through an activation function, such as a sigmoid or softmax, depending on whether the classification task is binary (microsatellite instability MSI vs. microsatellite stability MSS) or multi-class. For MSI prediction, a sigmoid function is typically used, outputting a probability value between 0 and 1. The final output of the model is a single probability value indicating the likelihood of the slide being MSI. A threshold (e.g., 0.5) is applied to this probability to make a binary decision.

3 Data

For this paper the MCO study [5] was used for training and testing. The MCO study collection contains 1,500 digitized whole slide images (WSIs) of colorectal cancer tissues. Conducted by the Molecular and Cellular Oncology (MCO) Study group from 1994 to 2010, this study systematically gathered tissue samples

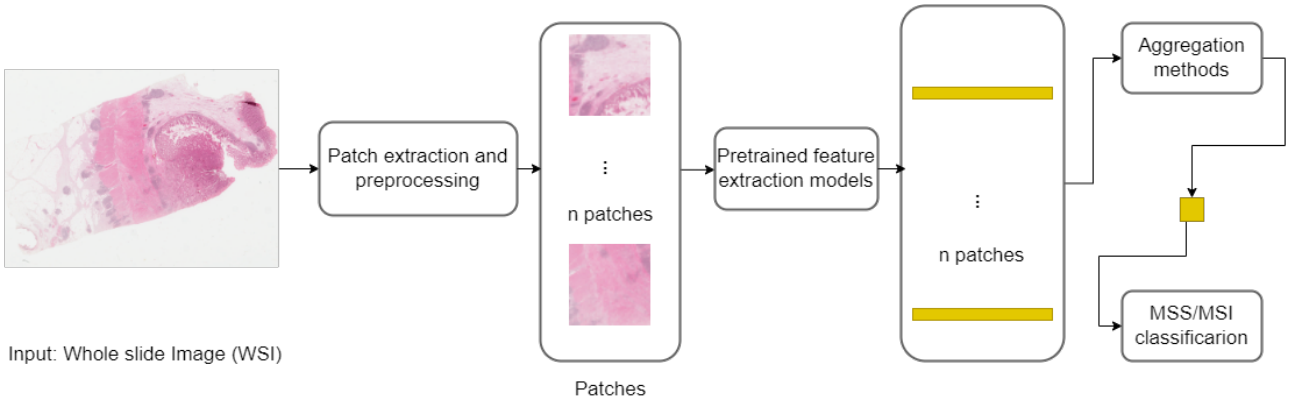

Figure 1: General architecture: multiple-instance learning approach.

feature extractor	architecture	dataset	embedding size
UNI [1]	ViT-large, DINOv2, 16 heads	Mass-100k: in-house histopathology slides from MGH and BWH, and external slides from the GTEx consortium containing >100M images, derived from >100,000 WSIs across 20 major tissue types	1024
ProvGigaPath [13]	ViT-large, DINOv2, 24 heads	Prov-Path: dataset from Providence, a large US health network comprising 28 cancer centres, consisting of 1,3B images from 171,189 WSIs	1536
Phikon [2]	ViT-large, iBOT combining MIM and CL	PanCancer40M: dataset from TCGA, covering 13 anatomic sites and 16 cancer subtypes, consisting of 43,4M images from 6,093 WSIs	768
CTransPath [12]	CNN with multi-scale Swin Transformer	dataset from TCGA and PAIP, consisting of 15M images from 32,220 WSIs	768

Table 1: Technical details about the pretrained feature extraction models.

and clinical data from over 1,500 patients who underwent colorectal cancer surgery. Each slide, representing a typical tumor section, is stained with Hematoxylin and eosin and scanned at a 40x objective, achieving a resolution of 0.25 mpp comparable to an optical microscope (~100,000 dpi). The total data size is approximately 3 Terabytes, and the collection is available on the Intersect Australia RDSI Node.

4 Results

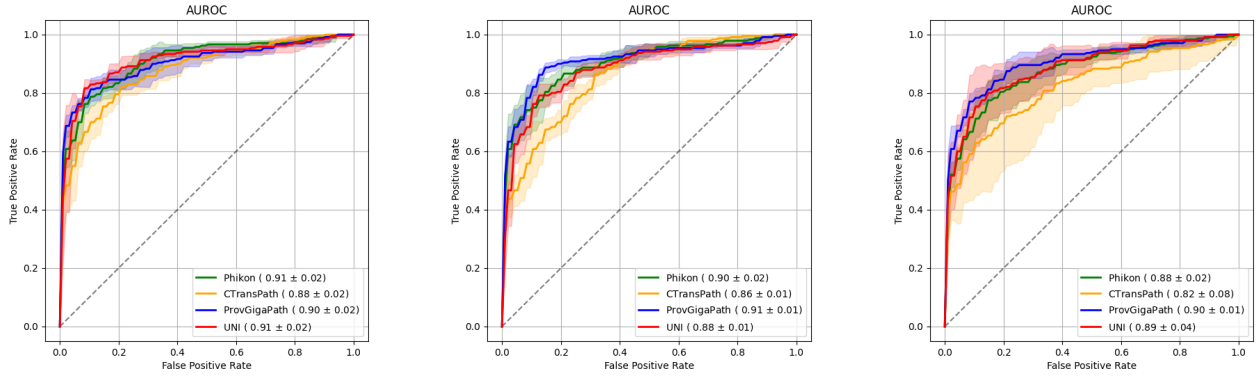
The dataset used in this study comprised 996 whole slide images (WSIs), with 242 labeled as MSI and 754 as MSS. To evaluate the performance of various aggregation methods, models were trained using 5-fold cross-validation, which ensured robust training and validation. To create a balanced testing set of 96 samples, 20% of positive (MSI) samples and an equal number of negative (MSS) samples were randomly excluded. The remaining data was split into five equally balanced parts for cross-validation, with each fold consisting of 180 samples in the validation set and 720 samples in the training set.

WSIs were then preprocessed into bags, each containing approximately 2,000 to 4,000 patches. Each patch was then converted into feature embeddings using four different feature extraction methods: Phikon, CTransPath, ProvGigaPath, and UNI. Specifically, CTransPath and Phikon produced embeddings with 768 features, UNI with 1024 features, and ProvGigaPath with 1536 features.

Three feature aggregation methods—ABMIL, DSMIL, and TransMIL—were applied to the extracted features to generate a single representative feature for each WSI. Following aggregation, a simple neural network with a sigmoid activation function and a threshold of 0.5 was used to classify MSI and MSS.

Each aggregation model was then trained for each feature extraction method on each fold, with training being conducted over 50 epochs using the AdamW optimiser and the 1-cycle learning rate scheduler to adjust the learning rate as models approached convergence. Binary cross-entropy (BCE) was used as the loss function. After each epoch, model performance was evaluated on the validation set using the AUROC metric to select the best checkpoint, as most models tended to overfit toward the end of training. The selected checkpoints were then tested to calculate the mean AUROC across all folds.

Results are presented in Figure 2a. The best performance was achieved using the DSMIL aggregation method with the ProvGigaPath feature extractor, yielding an AUROC of 0.91 ± 0.01. The ABMIL method performed best with the Phikon and UNI extractors, achieving AUROCs of 0.91 ± 0.02. Finally, the TransMIL method combined with ProvGigaPath resulted in an AUROC of 0.90 ± 0.01. Additionally, statistical analysis was performed, specifically, the Wilcoxon signed-rank test, which yielded an average p-value of 0.446, showing a relatively insignificant difference in performance of different feature extraction methods, as expected.



(a) ABMIL **(b) DSMIL** **(c) TransMIL**

Figure 2: Predictive performance of 5-fold cross-validation of different feature extractors and aggregation methods. AUROC plots for prediction of MSI/MSS status. The true positive rate represents sensitivity and the false negative rate represents 1-specificity. The shaded areas represent the standard deviation (SD). The value of the lower right each plot represents mean AUROC ± SD.

5 Discussion and Conclusion

n this study, we explored the potential of MIL combined with SOTA pretrained models for predicting MSI in colorectal cancer. Our results indicate that the approach is highly effective, achieving an AUROC of 0.913 on the MCO dataset. This is a notable achievement, particularly when compared to previous studies, such as [4] and[11], which reported AUROCs of 0.92 and 0.85, respectively, on the same dataset. Our results not only validate the effectiveness of our approach but also suggest that the careful selection and combination of feature extraction and aggregation methods can yield improvements in predictive accuracy.

The positive and negative rates observed in our results reflect the model's ability to correctly classify MSI and MSS cases. A high true positive rate (sensitivity) indicates the model's proficiency in identifying MSI-positive cases, which is crucial for ensuring that patients who could benefit from MSI-targeted therapies are accurately identified. Conversely, a high true negative rate (specificity) shows the model's effectiveness in correctly classifying MSS cases, thereby minimising false positives. To further enhance the accuracy and reliability of MSI prediction, several avenues for future work are planned.

Utilisation of the Entire Dataset: We plan to leverage the full dataset to improve the robustness of our model. Training on a larger dataset may help in capturing more nuanced patterns and variations, leading to even more accurate predictions.

Fine-Tuning of Pretrained Models: While we used pretrained models without fine-tuning in this study, fine-tuning these models specifically for the task of MSI prediction could further improve their performance. Tailoring the models to our specific data distribution and task requirements may yield significant gains in accuracy.

Incorporation of a Tissue Classifier: Since MSI is typically found in tumor tissue, we plan to integrate a tissue classifier to automatically remove non-tumor tissue from the analysis. This step should enhance the model's focus on relevant tissue regions, potentially improving MSI prediction accuracy and speed up the whole process.

Development of Advanced Aggregation Methods: We also plan to explore more sophisticated aggregation techniques that can better capture the complex relationships between patches within a WSI. Advanced methods may help in refining the prediction process, leading to further improvements in model performance.

Overall, our study demonstrates the potential of MIL-based approaches in enhancing biomarker prediction in colorectal cancer, paving the way for more personalized and effective treatment strategies.

Abstract

The field of emotion recognition from eye-tracking data is well-established and offers near-real-time insights into human affective states. It is less obtrusive than some other modalities, such as electroencephalogram (EEG), electrocardiogram (ECG) and galvanic skin response (GSR), which are often used in emotion recognition tasks. This study examined the practical feasibility of emotion recognition using an eye-tracker with a lower frequency than that typically employed in similar research. Using ocular features, we explored the efficacy of classical machine learning (ML) models in classifying four emotions (anger, disgust, sadness, and tenderness) as well as neutral and "undefined" emotions. The features included gaze direction, pupil size, saccadic movements, fixations, and blink data. The data from the "emotional State Estimation based on Eye-tracking database" was preprocessed and segmented into various time windows, with 22 features extracted for model training. Feature importance analysis revealed that pupil size and fixation duration were most important for emotion classification. The efficacy of different window lengths (1 to 10 seconds) was evaluated using Leave-One-Subject-Out (LOSO) and 10-fold cross-validation (CV). The results demonstrated that accuracies of up to 0.76 could be achieved with 10-fold CV when differentiating between positive, negative, and neutral emotions. The analysis of model performance across different window lengths revealed that longer time windows generally resulted in improved model performance. When the data was split using a marginally personalised 10-fold CV within video, the Random Forest Classifier (RF) achieved an accuracy of 0.60 in differentiating between the six aforementioned emotions. Some challenges remain, particularly in regard to data granularity, model generalization across subjects and the impact of downsampling on feature dynamics.

Keywords

eye-tracking, emotion recognition, machine learning

1 Introduction

Emotion recognition is a vibrant area of research, leveraging diverse data sources such as images [11], audio [16], and also, ocular features like pupil dilation, gaze direction, blinks, and saccadic movements [3, 8, 12]. Such eye-related features provide valuable insights into emotional states, offering a less-invasive and real-time approach to understanding human affective responses. Most studies that tried to predict emotions from these eye-related features relied not only on eye-tracking data but also on EEG [8, 12]. We hypothesized that eye-tracking data is a valuable modality for multi-modal emotion recognition on its own, with potential applications in real-world scenarios like office work, driving, and psychological assessments, as well as in estimating well-being. Our motivation was to explore eye-tracker-based predictive models as an essential component in such practical applications.

The primary objective of our study was to validate existing findings on the performance of classical ML models for emotion classification from eye-tracking data, using the models – Support Vector Machine (SVM) and k-Nearest Neighbors (KNN) – and features already explored in the literature [9, 15] as well as exploring classifiers not so frequently used in this field – such as RF and XGBoost (XGB). Additionally, we aimed to explore the potential of emotion recognition at lower sampling frequencies available in most non-professional eye trackers. For the early feasibility study, we used an existing dataset, which collected data using a wearable eye-tracker but findings could possibly be extended to high-quality unobtrusive contact-free trackers. Our research also focused on understanding the impact of individual features and window lengths on model performance.

2 Related Work

In literature, various physiological signals have been employed for emotion recognition, with a particular focus on modalities such as EEG, GSR, and eye-tracking systems [1, 6, 9]. Researchers have explored both uni- and multi-modal approaches, finding that the integration of multiple modalities can significantly enhance emotion recognition accuracy. Lu et al. achieved 0.78 accuracy with eye-related features recorded with eye-tracking glasses – which are not contact-free but record at relatively low frequencies of 60 Hz or 120 Hz. They predicted positive, negative and neutral classes with SVM. Interestingly, they observed a 0.10 increase in accuracy when combining eye-related and EEG features [12]. Similarly, Guo et al. observed a more substantial gain, with accuracy improving by 0.20 when integrating EEG, eye-tracking, and eye images, as opposed to using only eye-tracking data [7].

The features derived from eye-tracking have been widely used in ML algorithms to detect emotional states [2, 7, 12, 15]. However, most studies have traditionally categorized emotions into broad groups like positive, negative, and neutral [12, 14]. Pupil size, in particular, has emerged as a valuable indicator for distinguishing between positive and negative emotions [2, 7, 12] . Recent efforts have begun to refine these broad categories, identifying more specific emotions like happiness, sadness, fear, anger, etc. [2, 7, 15]. Although current methods can effectively identify certain emotions such as sadness and fear, further research is needed to reliably differentiate between others like disgust, joy, and surprise [2].

3 Methodology

3.1 Data

In our research, we used the "emotional State Estimation based on Eye-tracking database" (eSEEd) [13]. The eSEEd comprises data from 48 participants, each of whom watched 10 carefully selected videos intended to evoke specific emotional responses. After viewing each video, participants ranked their emotions – anger, disgust, sadness, and tenderness – on a scale from 0 to 10. Tenderness, however, is not regarded as one of the basic emotions, but it has been widely utilized in emotion research in recent years [13]. Since the participants had ranked all four emotions for every video, a labelling problem emerged when multiple emotions shared the highest score, in our case, leading to "undefined" labels. In our study, emotions were mapped by applying a set of extraction rules in the following order: if the highest-ranked emotion is below four, the response is labelled as neutral; if multiple emotions share the highest rank, the label is undefined; otherwise, the emotion with the highest rank is chosen. The boundary of four was chosen because the original study on eSEEd constructed this rule and we adapted it from there [13]. Although the initial study design aimed for an even distribution of emotions, neutral responses dominate, representing about one-fourth of the labels (depending on window length).

3.1.1 Data Preprocessing. We have preprocessed the data to make it more suitable for our future research and to reduce its size. We wanted to study the performance of data with a relatively low frequency rate of 60 Hz, which is used by relatively affordable mid-tier eye-trackers, like Tobii Pro Spark. Firstly, the features that were uninformative or could be misleading (e.g. raw tracker signal and timestamps) were removed, and the following set of features was preserved: 2D screen coordinates of gaze points (for standard deviation (std) of screen gaze coordinates), 3D coordinates of gaze points (exclusively for saccade calculations), pupil sizes (a and b of the pupil ellipse), and eye IDs (each eye has its own pupil size features). Secondly, rows containing any NaN values were removed, as there were no large consecutive blocks of such rows and downsampling of the data was planned. Finally, we further downsampled the data to 60 Hz, matching the sampling frequency of a mid-tier eye-tracker. However, we acknowledge that downsampling might lead to the loss of high-frequency information, which could be important for capturing subtle dynamics in gaze behaviour and pupil responses. This is particularly relevant considering that recent studies, such as those by Collins et al. [3] and the SEED project [4, 17], have utilized data collected at much higher frequencies to preserve these subtle dynamics. Therefore, while downsampling makes the data more meaningful to our research and more computationally manageable, it is important to keep in mind the reduced temporal resolution when discussing the results.

Following the preprocessing, window segmentation was applied to the data. This step is essential for analyzing temporal patterns within the data, as it allows for the capture of trends and behaviours over specific time intervals. By segmenting the data into windows, we can improve the robustness of feature extraction and model training, enabling the detection of meaningful patterns that might be obscured in raw, unsegmented data. Additionally, with window segmentation, the number of training instances increases which is commonly better for learning more robust ML models and conducting rigorous evaluation. Hence, multiple window lengths were examined, namely: 1, 3, 5 and 10 s. We used 50% sliding window overlap. From each window, we computed 22 features, belonging to the following groups:

(1) gaze coordinates on screen: std of x and y coordinates
(2) pupil ellipse sizes of a and b for each eye: mean, std
(3) blinks: number; mean and std of duration (all 0 if no blinks)
(4) saccades: number; mean speed; mean, std, total duration
(5) fixations: number; mean, std, total duration

Saccade and, implicitly, fixation calculations were done using existing code based on the algorithm proposed by Engbert et al. [5, 10]. The algorithm calculates the velocity and acceleration of eye movements by using a velocity threshold identification method to detect saccades based on continuous 3D gaze data. In our study we define fixation (interval) as an absence of a saccade (interval), thus one fixation is declared between every two saccades (and before the first and after the last one).

As mentioned previously, our data was imbalanced in terms of class distribution, namely the distributions for anger, disgust, sadness, neutral, tenderness and undefined were 8.7%, 13.6%, 17.5%, 25.7%, 15.8% and 18.7%, respectively. Notably, for the 1 s window length, the number of windows was 67,181, whilst for the 10 s window, the number of instances decreased to 6,507.

3.2 Experiments

We initially examined feature correlation matrices to identify potential correlations between features, as well as between feature and class. Then, we compared the following classifiers from the Scikit-learn library: Random Forest (RF), Support Vector Machines (SVM), k-Nearest Neighbors (kNN), and XGBoost (XGB) from the XGBoost library, as well as an ensemble method majority vote of the aforementioned classifiers. We compared all results against a baseline majority classifier. Each model was trained and tested using its default hyperparameters. To evaluate the models' performance, we implemented multiple CV techniques.

The first CV technique was Leave-One-Subject-Out (LOSO). Secondly, we implemented a marginally personalised 10-fold CV "within video." In this approach, a standard 10-fold CV was performed where 90% of temporally sequential windows were used for training and 10% for testing. The splits were done separately for each video within every subject. All the training data from every video was combined to train a single model, and all the test data was combined to evaluate the model, ensuring that the model was exposed to data from all subjects and videos. We named the experiment "marginally" personalised because most training data does not come from any single subject and is thus not very personalised. Finally, we explored a completely personalised 10-fold CV "within subject." Here, training and testing were done only on data of one subject. In all three CV methods, the instances were never shuffled to preserve temporal and subject sequential information and to minimize overfitting.

We attempted to merge certain classes in a way to group negative emotions – anger, disgust, and sadness – under the category "negative," while labelling tenderness as "positive." The label for neutral remained unchanged, while the undefined label was changed to "negative" because it always resulted from multiple negative emotions scoring equally. Lastly, the feature importances were analysed for different combinations of data splits and models in order to identify potential consistently important features.

4 Results

The results described in the following subsections are summarised in Table 1.

4.1 Feature Correlations

The first important observation from correlation matrices was that no output class is closely correlated to any other singular feature. Secondly, we noticed some strong correlations, for example, a 1.0 correlation between a number of fixations and a number of saccades, because one simply equals the other increased by one. More importantly, we noticed little-to-no correlation between features that proved to be most important in some best-performing models, meaning each of these features brought some novel information to the model. The only exceptions of important features being correlated are the features representing the mean size of a pupil i.e., ellipse a and b axes, which are expected to be correlated. They were correlated more than 0.8. However, we decided not to remove any features because we assessed the feature count of 22 to be well-balanced in relation to the number of instances.

4.2 Leave-One-Subject-Out

With the goal of training a robust general model for our dataset, we first applied the LOSO CV technique. The best performance was achieved by RF on 10 s windows, yielding an accuracy of 0.28 ± 0.13 and an F1-score of 0.28 ± 0.16. It outperformed the majority classifier by 0.03 in accuracy and 0.13 in F1-score. In a subsequent experiment, the negative emotions were grouped. This adjustment led to an overall increase in performance. However, with such grouping the majority classifier score also increased to 0.59 accuracy, which is the same as the best-performing model.

Further analysis revealed that high accuracy mainly implied the subject predominantly reported "neutral" feelings and low accuracy implied little-to-no "neutral" labels. However, not every subject with a high "neutral" count achieved outstanding results and not every subject with a wide range of emotions yielded poor results. A comparison was made between the number of windows in the left-out subject to their performance and no correlation was found. 10 s window length performed better than the shorter windows with lengths 1-5 s. We also tested longer (60 s) windows and the resulting accuracies were higher than those from 10 s windows, but we evaluated that the number of instances was insufficient for the results to be representative.

4.3 Marginally Personalised 10-fold Cross-Validation Within Video

Given that the LOSO yielded relatively poor results, the next step was to explore 10-fold CV. Experiments showed an average accuracy of 0.60 ± 0.07 and an F1-score of 0.60 ± 0.08, produced with RF on 10 s windows, the best-performing model. This should be compared to the results given by the majority classifier – average accuracy of 0.21 ± 0.01 and F1-score of 0.07 ± 0.01. With negative emotions grouped, the accuracy and F1-score raised to 0.76 ± 0.04 and 0.73 ± 0.04, respectively, for the best-performing XGB on 10 s windows. The majority class classifier yielded an accuracy of 0.66 ± 0.02 and an F1-score of 0.52 ± 0.02.

4.4 Personalised 10-fold Cross-Validation

Even though 10-fold CV within video resulted in much better performance compared to LOSO, we wanted to see the performance of completely personalised models. All the models performed similarly well, with the absolute best being RF on 10 s windows which outperformed the majority classifier by 0.05 and 0.13 for accuracy and F1-score, respectively. When grouping the negative emotions, we observe an absolute improvement in models' performance, but a relative decline toward the majority classifier benchmark. The best model, in this case, did not surpass the majority classifier in terms of accuracy, with the majority classifier achieving 0.67 ± 0.16 accuracy and 0.61 ± 0.16 F1-score, while SVM, the best-performing model, scored an accuracy of 0.64 ± 0.13 and an F1-score of 0.63 ± 0.12.

4.5 Feature Importances

Following the completion of model training, we analyzed the feature importances of the best-performing models. For RF this was calculated based on the Mean Decrease in Impurity, summing the impurity reduction each feature contributes across all trees; and for XGB, feature importances were calculated using the "weight" metric, which counts the number of times each feature is used to split the data across all trees. For SVM we did not calculate feature importances. In the completely personalised 10-fold experiments, feature importances varied significantly across different subjects and even between different runs within the same subject, specifically with RF, as the random state was not fixed. In contrast, feature importance was notably consistent in experiments where models were trained on data from multiple subjects, such as in the LOSO and the 10-fold within video, even with a variable random state of the RF model.

The most important features of best-performing models were those related to average pupil sizes, followed by fixation duration. These results partially align with those of Collins et al., who found features relating to pupil diameter and saccades statistically significant [3].

5 Conclusion

Our research explored emotion classification using eye-tracking data with classical ML models and hand-crafted features. The data was downsampled to a lower-than-standard frequency i.e., to 60 Hz, which was more realistic for consumer contact-free eye-tracker data. This made the problem harder, making it not directly comparable with other studies working on eSEEd, but valuable from a practical perspective.

Window segmentation significantly impacted model performance, with the best results constantly obtained using the largest window length. This suggests that longer observation periods capture more comprehensive information, making smaller windows less effective for emotion classification. We hypothesize that this does not transfer to realistic scenarios, as users might experience emotions in short bursts while being neutral for the majority of the time. In specifically designed cases where emotion is consistently induced for longer periods of time (like our dataset), this is more expected.

The LOSO validation strategy, which tests model generalization across different subjects, yielded poor results. The variability in performance across subjects indicates the challenge of capturing general relationships between eye features and emotions. While both 10-fold CV approaches showed an increase in performance, their generalizability is limited. Completely personalised 10-fold showed worse results than the marginally personalised one presumably because of the low number of videos per emotion within an individual subject.

Table 1: Best-performing models and their corresponding results along the results of the Majority Class Classifier for the same parameters. Window lengths are 10 s.

Settings	**Model Acc**	Model F1	Majority Class Acc	Majority Class F1
LOSO, RF	**0.28 ± 0.13**	0.28 ± 0.16	0.25 ± 0.25	0.15 ± 0.26
LOSO, SVM, negative emotions grouped	**0.59 ± 0.19**	0.46 ± 0.18	0.59 ± 0.19	0.46 ± 0.18
10-fold within video, RF	**0.60 ± 0.07**	0.60 ± 0.08	0.21 ± 0.01	0.07 ± 0.01
10-fold within video, XGB, negative emotions grouped	**0.76 ± 0.04**	0.73 ± 0.04	0.66 ± 0.02	0.52 ± 0.02
10-fold within subject, RF	**0.38 ± 0.20**	0.42 ± 0.19	0.33 ± 0.26	0.29 ± 0.26
10-fold within subject, SVM, negative emotions grouped	**0.64 ± 0.13**	0.63 ± 0.12	0.67 ± 0.16	0.61 ± 0.16

An important issue with the eSEEd data is that all participants watched the same 10 emotion-evoking videos in the exact same order. This uniformity raises concerns that, given the small number of videos (two intended[1] per emotion), the models might learn to associate features unrelated to emotions, such as video dynamics or illumination. We circumvented the problem with video dynamics by dropping the mean gaze coordinate features and not using them in our experiments.

Despite these challenges, our experiments offer valuable insights into the feasibility of emotion recognition from low-frequency eye-tracker data, providing a foundation for future work. We opted for classical models initially due to their explainability, lower computational complexity, and efficiency, which are in our opinion essential for understanding the data before transitioning to more complex deep learning models.

In future work, several enhancements could be explored to improve the robustness and accuracy of emotion classification models using eye-tracking data. One approach could involve analyzing distinct fixation areas as an additional feature, potentially offering deeper insights into visual attention patterns. Moreover, considering that each emotion is (in some cases) represented by two videos, a valuable experiment would be to train models on one video and test on the other. This could help assess the model's ability to generalize across different stimuli within the same emotional category.

Further analysis could focus on demographic factors by examining the LOSO results for potential correlations between model predictions and participant characteristics such as gender, age, and education. This might reveal underlying biases or trends that affect model performance. Additionally, rather than downsampling and removing rows with missing data, future work could explore retaining or imputing these rows.

Furthermore, exploring the training of neural networks on raw, non-downsampled data from multiple modalities is another promising direction, as other studies already observed promising results with such approaches. Moreover, we should address the issue of overlapping emotions which could involve developing a multiclass output model, reflecting a real-world scenario where multiple emotions can be present simultaneously. This approach could also help reduce the number of undefined labels, increasing the amount of useful data.

PREDGOVOR

Dobrodošli na konferenci Kognitivna znanost. Na letošnji konferenci bodo avtorice in avtorji raziskovali mnoge plati človeške kognicije in predstavili tako svoje empirične ugotovitve kot tudi teoretska raziskovanja. Poleg prispevkov s področja teme letošnje konference, "Preseganje vrzeli v raziskovanju in razumevanju uma", bomo potovali skozi različna področja kognitivne znanosti - od psihologije in nevroznanosti do filozofije in umetne inteligence, ter ob tem spoznavali raznolike tematike vključujoč uporabo VR tehnologij pri raziskovanju kognicije, uporabo inteligentnih tehnologij pomoči pri demenci, uporabo dregljajev za spreminjanje vedenja, vpliv umetne inteligence na demokracijo, izzive vzorčenja izkustva in manj poznane vidike doživljanja kot so ozadnja občutja.

Konferenca se bo zaključila z okroglo mizo, na kateri bomo razmišljali o izzivih, ki jih prinašajo vrzeli v raziskovanju in razumevanju v kognitivni znanosti: med drugim o združevanju prvo- in tretje-osebnih pristopov k raziskovanju človeškega uma, o povezovanju različnih nivojev opazovanja (na primer mikro-nivoja nevrološke aktivnosti z makro-nivojem vedenja in družbenih sistemov) ter o izzivih povezovanja različnih disciplinarnih pristopov.

Upamo, da bo letošnja konferenca predstavljala prostor radovednega povezovanja in izmenjave kreativnih idej. Skupaj bomo premagovali disciplinarne in metodološke ovire, združili mlade in izkušene znanstvenike ter znanstvenice, ki si delijo strast do raziskovanja skrivnosti kognicije.

Dobrodošli!

FOREWORD

Welcome to the Cognitive Science Conference. At this year's conference, authors will explore the many facets of human cognition and present both their empirical findings and theoretical research. In addition to contributions on the topic of this year's conference, Bridging the Gaps in Research and Understanding the Mind, we will explore a diverse range of fields of cognitive science – from psychology and neuroscience to philosophy and artificial intelligence – while also learning about various topics, including the use of VR technologies in research, the use of intelligent assistive technologies for dementia, the use of nudges to change behavior, the impact of artificial intelligence on democracy, the challenges of sampling experience, and explore the less known aspects of experience, such as background feelings.

The conference will conclude with a roundtable discussion, where we will reflect on the challenges posed by gaps in research and understanding of mind in cognitive science: among others, we will think about the integration of first- and third-person approaches to studying the human mind, the relation and possible links between different levels of observation (for example, the micro-level of neurological activity and the macro-level of behavior and social systems), and the challenges of connecting different disciplinary approaches.

We hope that this year's conference will be a space for networking and sharing insightful ideas. Together we will overcome disciplinary and methodological barriers, bringing together young and experienced scientists who share a passion for exploring the mysteries of cognition.

Welcome!

The Ontological Shock: What Psychedelics can Teach us about the Nature of the Mind

Maruša Sirk

marusasirk@gmail.com

ABSTRACT

The following article provides a brief overview of the significance and potential challenges of profound psychedelic experiences that prompt individuals to question the nature of reality, often referred to as "ontological shocks." These experiences are believed to induce changes in the structure of consciousness, leading to subsequent shifts in worldviews, behaviors, relationships, and mental health. While they can result in long-lasting positive changes, they are not always pleasant. Due to the complex alterations these experiences produce, they offer a unique opportunity to explore gaps in our understanding of the human mind and the nature of the reality it perceives, enacts, or constructs. The article aims to raise awareness of these issues by shedding light on various aspects of the discourse surrounding this topic.

KEYWORDS

psychedelics, ontological shock, mind, consciousness

1 INTRODUCTION

Psychedelics are psychoactive substances that can lead to altered states of consciousness, experienced as a change in perception and cognitive processes. Classic psychedelics, such as psilocybin, mescaline, LSD and DMT, primarily act through the stimulation of the serotonin 5HT-2A receptor. Due to somewhat similar psychological effects, substances such as MDMA and ketamine are also sometimes considered as psychedelics even though they target different neurological structures [1].

In recent years, there has been a growing interest in research on the potential use of psychedelic substances for mental health treatment. There are many studies that support this claim [e. g. 2, 3, 4], but there is also evidence that psychedelics can lead to longer lasting adverse effects [e. g. 1, 5].

Some of the challenges that may emerge after a psychedelic experience stem from profound shifts in one's worldview [6], metaphysical beliefs [7], and an overall ontological shock [8], in which the individual begins to re-evaluate the nature of their reality. Commonly, people also experience a shift in their spiritual orientation [9], due to experiences that have been labeled as “spiritual emergencies” [10]. These include transpersonal experiences, out-of-body experiences, hallucinations of religious nature etc. [10].

In this paper, we will tackle the problem of the “ontological shock” that can arise due to psychedelic experiences, how individuals cope with them and what implications they have on our understanding of the mind.

2 ONTOLOGICAL SHOCK FOLLOWING THE USE OF PSYCHEDELICS

As interest in researching psychedelics for their potential therapeutic effects increases, there is a growing need to understand the mechanisms that enable these changes to occur. Changes in metaphysical beliefs are thought to be one of the driving mechanisms of change that enable the transformational process to occur [8]. However, changes in metaphysical beliefs don’t come easily, as they normally induce the so-called ontological shock about the nature and reality of existence [8]. This means that people start to question the nature of (their) reality and subsequently come to adopt an altered belief system, commonly constituting beliefs such as animism, life after death, the existence of alternative realities etc. [7].

On one hand, psychedelic experiences are often reported to be among the most meaningful and significant experiences, leading to positive long-term changes [11]. On the other hand, many individuals report prolonged difficulties after a profound psychedelic experience, struggling with ontological challenges as they question their own reality and existence [8]. This presents ethical challenges in both formal and informal practices for integrating psychedelic experiences, while also raising broader questions about the nature of reality itself.

2.1 Coping with the ontological shock

Psychedelic experiences that possess mystical qualities—characterized by feelings of ineffability, significance, and the perceived “trueness” of the experience—are more likely to result in an ontological shock and lead to a transformed belief system [12]. These experiences can offer profound insights into the "oneness" of reality and foster a sense of "ontological comfort," bringing a greater sense of purpose and meaning to life. However, they can also present challenges, as individuals may struggle to integrate these insights into their everyday lives. This raises the question of how best to support people in making sense of these new ontological truth claims [12].

Challenging psychedelic experiences can lead to various ontological difficulties, such as questioning one's identity,

grieving the loss of a past self, experiencing persistent encounters with (spiritual) entities, psychotic episodes, spiritual grandiosity, feelings of meaninglessness and emptiness, isolation and despair [8], derealization, delusional beliefs, and experiences of possession [9]. These prolonged challenges can impact individuals in different ways, resulting in difficulties with everyday interactions, attentional problems, disruptions at work [8], challenges in managing emotions, and perceptual difficulties [9].

Research on the adverse effects of psychedelics [e.g. 13, 14, 15, 16] and the challenges that arise following the so-called ontological shocks these experiences can induce [e.g. 1, 8, 9] highlights the importance of developing therapeutic practices and guidance rooted in empathic resonance and the concept of psychedelic apprenticeship [6]. While there are many existing therapeutic and shamanic frameworks aimed at making sense of psychedelic experiences [6], it is crucial to recognize that these experiences often lead to heightened suggestibility [17], which must be considered when helping individuals navigate their shifting worldviews. People have reported various strategies that helped them cope with extended difficulties, such as meditation, embodied contemplation, self-education through reading and journaling, and physical exercise. In terms of support from others, individuals expressed a need to feel seen, heard, understood, believed, and to have their experiences accepted and validated [1, 8]. This suggests a responsibility for practitioners working with and guiding people through psychedelic experiences to help them find meaning in their experiences without imposing any specific ontological truth claims [12].

Extensive research on challenging psychedelic experiences, including work by Stanislav Grof's clinical team, has identified common existential challenges that individuals often face following these experiences, primarily centered around fears of dying, going insane, or losing control [18]. According to Grof's team, psychedelic experiences can activate deep existential concerns that only subside once the individual has successfully processed them. It is suggested that people may encounter a sense of the groundlessness of being [18], which can be understood as an underlying "principle" of cognition. This brings us to the next point of this paper: the implications these experiences might have for the scientific understanding of the mind.

3 POSSIBLE IMPLICATIONS ON UNDERSTANDING THE MIND

3.1 Understanding psychedelic experiences

The underlying mechanisms that facilitate changes after the use of psychedelics have yet to be fully understood. However, several hypotheses have been proposed to explain how these cognitive shifts might occur. One prominent hypothesis is based on the framework of predictive processing [19]. This framework conceptualizes the mind as a "prediction machine" that continuously balances information by integrating prior knowledge about the world with incoming sensory data from the environment [19].

Within this framework, the "Relaxed Beliefs Under Psychedelics" (REBUS) model suggests that psychedelics increase the brain's level of entropy—or uncertainty—while reducing reliance on prior beliefs, thereby allowing more room for new sensory information [20]. This process can lead to the dissolution of previously rigid mental models and established worldviews. The resulting experience of an ontological shock may represent a direct encounter with the fundamental uncertainty of reality [8]. This concept, referred to as "groundlessness," attempts to explain how individuals continuously construct a world of meaning that is inherently without a fixed foundation and perpetually in flux [21].

It is important to note that psychedelics can also reinforce existing beliefs, potentially enhancing established worldviews, mental models, and expectations [22]. To address this complexity, the "Altered Beliefs Under Psychedelics" (ALBUS) model proposes that the effects of psychedelics on prior beliefs depend on factors such as the dose consumed and the individual's pre-existing state of mind [22]. This model aims to explain how psychedelics can both diminish and strengthen prior beliefs, bridging gaps between different proposed mechanisms of how psychedelics influence reality and well-being [22].

Additionally, other models offer explanations for the mechanisms of action of psychedelics. The "Cortical-Subcortical Communication Theory" (CSCT) suggests that psychedelics reduce thalamo-cortical filtering of internal and external stimuli, allowing new, unfiltered sensory information to emerge [23]. The "Cortical-Claustrum Communication" (CCC) model posits that psychedelics decouple cortical areas from the claustrum, leading to reduced cognitive control [24]. Furthermore, psychedelics are thought to open a critical period for social learning, potentially fostering new social behaviors and reducing tendencies toward isolation [25].

These various theories attempt to explain how psychedelics can facilitate the creation of new cognitive models of the world and reality. However, the field of psychedelic research continues to grapple with understanding the precise mechanisms of these substances, with ongoing testing of competing theories and hypotheses. For a comprehensive evaluation of these theories, see [26].

There is also an ongoing debate about the role of subjective experiences in the transformative effects of psychedelics. Some researchers take on a reductionist approach, focusing solely on the brain mechanisms involved [27, 28]. This is problematic, as it opens the question of how to understand the profound ontological shocks and the integration of the psychedelic experience in everyday lives of individuals. It is also problematic, as evidence suggests that psychedelic experiences with rich subjective effects, such as mystical-type experiences, can lead to the most significant transformations [29, 30]. If transformative effects were purely mechanistic, without considering subjective experiences, it becomes challenging to explain the struggles and positive changes individuals report in their daily lives after using psychedelics.

Subjective experiences cannot be easily dismissed [31, 32, 33, 34], and they are crucial for understanding how people's ontological reality gets altered. Investigating these subjective aspects could help address some of the unresolved questions about the mind. Studying the invariants and stable states of the "changing mind" following psychedelic use may bring us closer to unlocking the nature of the mind. This research could have implications for not only understanding and treating mental health issues but also for exploring concepts like consciousness [22, 36, 37] and the self [22, 33, 35, 38]. Additionally, it could

impact the reductionist debate [32], consciousness theories, and discussions about the "easy" and "hard" problems of consciousness [22, 36, 37].

3.2 Possible contribution to understanding the mind

In previous sections, we provided a short overview of what psychedelics are and sketched some possible implications they can have in the everyday lives of people, as well as our broader impact they may have on our understanding of the mind. In the last section we want to finish with diving a bit deeper into some possible implications that ontological shocks can have on understanding the mind.

Let us stop for a moment on how we understand the concept of the “mind”. This is an important question as the theories of psychedelic mechanisms all have their own postulates, the prevalent implicit view being that the mind is a product of neuronal activity (which applies for previously presented theories – the REBUS [20], CSCT [23] and CCT model [24]). This is a reductionist view of the mind that equals the mind with the brain [39]. Another possible view is that the mind is an information-processing system that manipulates and transforms information, which is a computational view [40]. In the previous years, another understanding on the mind has slowly been evolving in cognitive science – that the mind is embodied, embedded, extended and enacted, which we call the 4E cognition. This view understands the mind as a complex interplay between the brain, body and the surrounding environment [41].

The challenge of understanding the mind mirrors the debate in psychedelic research about the significance of subjective experiences. The core issue is whether the relevance of a psychedelic experience depends solely on inducing specific brain states or requires a deeper subjective experience to impact a person's everyday life. Evidence increasingly supports the idea that both "set" (the interplay of personality, preparation, expectation, and intention) and "setting" (the physical, social, and cultural environment) play crucial roles during a psychedelic experience [42]. This observation could indicate the relevance of the 4E cognition framework, which views the mind as a dynamic interplay between brain, body, and environment. Moreover, the 4E cognition theory might explain why set and setting are important, and why some psychedelic states and doses lead to profound changes while others do not. By exploring this intricate interplay, the 4E framework may shed light on why certain individuals experience ontological shocks under specific conditions. If, however, these experiences are inexplicable through existing frameworks, they could highlight gaps in our current understanding of the mind and reveal how alternative states of consciousness can disrupt the established interaction between mind, body, and environment.

Psychedelic experiences are often described as "altered states of consciousness," suggesting that by examining what changes during these experiences, we can gain insights into what constitutes the "normal," "usual," or "everyday" state of consciousness. The concept of ontological shock, which we have frequently referenced, highlights a paradox within this framework. If a person's everyday consciousness is altered during a psychedelic experience, and they subsequently notice changes in their subjective experience in their daily life, does this mean that the new state is an unusual or extended form of consciousness? In other words, does this imply that the individual is now living in a perpetually altered state of consciousness?

There is a prevalent view that the subjective experiences induced by psychedelics reveal aspects of the mind that need to be integrated into everyday life [43]. This perspective suggests that psychedelics should be considered mind-revealing rather than merely mind-altering substances [44]. This leads us back to fundamental questions about the nature of consciousness itself. Is consciousness merely a byproduct of neuronal activity, something external waiting to be experienced, is it embodied, enacted, or something else entirely? What we do know at this point is that psychedelics can induce alterations in our consciousness, affecting our awareness of ourselves and the world around us.

While it may be ambitious to claim that psychedelic experiences will fully bridge the epistemic gap between first-person experiences and their third-person correlates, or help us understand the nature of consciousness itself – the problem we commonly refer to as the hard problem of consciousness [45, 36]–, they can still provide valuable insights into both these issues [35, 36]. The most profound psychedelic experiences, which often lead to significant changes in consciousness, self-perception, and belief systems, may offer particularly important insights.

4 CONCLUSION

The aim of this article was to present the concept of ontological shock following the use of psychedelics and possible implications on the scientific understanding of the mind. We provided an overview of what is already known about this topic, to point out where we should be cautious and what is still unknown or vaguely known, as well as to illustrate how diving deeper into this topic could help us scientifically advance our current understanding of the mind.

It is important to conclude this paper with a call for caution. As we tried to point out, psychedelic experiences and its subsequent changes in everyday experience can inform us about the nature of our mind and help us gain broader understanding about topics related to consciousness, self, mental health etc. But the experiences that could most inform us about these topics and can lead to most profound long-term changes, have its challenges and downsides, which should not be disregarded. That is why the integration process, as well as the importance of set and setting, should always be considered when dealing with these substances. But before we have a consensus on what the mind is and how it constructs our reality, a lot of damage can be done, especially if we want to use psychedelic substances to help people get through their mental health problems, as is the case in psychedelic research in the past years.

Abstract

How can individuals deal with personal trauma or internal struggles more effectively? This is the main question of every existential crisis, closely linked with humankind's survival strategy. Finding new, innovative ways for practitioners to leverage therapeutic techniques and modern *artificial intelligence (AI) technology* is crucial to providing precision mental health support to more individuals. While looking at possible approaches, it becomes more and more important to synthesize complex ways practitioners can provide multidimensional help. This paper investigates the possibility of a new holistic treatment that integrates *bibliotherapy's* storytelling, *Magic Shop* as a *psychodrama method*, and *AI conversation tools – chatbots* to ensure that individuals receive encompassing supportive therapy and feel less isolated. The holistic method is applied to *Korean pop* music as a case study, because K-pop content has experimented with these techniques and fandoms often have strong parasocial interactions. Combining these techniques creates a holistic, accessible, and personalized mental health care option that enhances the cognitive, emotional and practical well-being of individuals in need of support.

Keywords

Bibliography, storytelling, psychodrama, Magic Shop, AI, chatbots, K-pop

1 Introduction

The psychological aspect of overcoming personal issues and facing the harshness of reality is demanding for everyone. Internal cognitive mechanisms lead us to believe that individual struggles require individual approaches. This adaptation for hiding internal fights and presenting balance to the outside world is built under external pressure to achieve inner balance. However, emotional turmoil can be particularly challenging, which is why we need to explore a multimodal approach that could be a revolutionary step in interdisciplinary mental health support.

Bibliotherapy, psychodrama, and *AI* might initially seem unrelated, but there is a way to incorporate all of them within a new therapeutic framework.

2 Methodology

This paper uses a conceptual methodology to explore the integration of mental health techniques and *artificial intelligence* to theorize a holistic, accessible and personalized mental health care option. Based on the researchers' backgrounds and engagement with existing literature, *bibliotherapy, psychodrama* and *artificial intelligence* were chosen for further analysis. The researchers reviewed literature from databases including APA PsycInfo, Google Scholar, IEEEXplore, ProQuest, PubMed, Scopus, Web of Science and EBSCO. Only papers written in English and published after 2000 were considered, except for one foundational work (*Purpose and strategy behind the magic shop*). To build the theory, the researchers identified the prominent features of each topic (Table 1): *bibliotherapy's* storytelling, *psychodrama's* experiential model, and *AI's* real-time access, which will each be explored in subsequent sections. For an exploratory case study application, the researchers relied on new concepts (described in *6.1-6.3*) provided through the *Korean pop* music industry (concretely *group BTS*), initially produced as music-related products, but nowadays perceived through a therapeutic lens, with the primary aim of merging the separate therapies together, creating a more influential impact.

Approach	Method	Examples	Therapeutic Goal
Bibliotherapy	Individual therapy through storytelling	BTS: "The Most Beautiful Moment in Life" book series	Promote personal reflection and healing
Psychodrama	Magic Shop	BTS: "Magic Shop" song (metaphorical counselling setting)	Explore and resolve emotional conflicts
AI Chatbots	Parasocial interaction therapy	BTS: Weverse, Replica, Mydol	Provide emotional support and companionship
Integrated Approach	Psychodrama and digital interaction	BTS: Integration of storytelling, psychodrama, and digital interaction	Holistic support for the healing process

Table 1: Selection & Clarification for Chosen Approaches

3 Bibliotherapy

Storytelling has long been a powerful means of exploring and understanding human emotions, and this concept underpins *bibliotherapy*, a therapeutic approach that uses literature to support mental health and personal growth. By engaging with carefully chosen texts, individuals can reflect on their own experiences, gain new insights, and find comfort and empathy through the narratives. *Bibliotherapy* leverages the emotional and cognitive impact of stories to address psychological challenges, offering a complementary and accessible method for fostering emotional healing and resilience [1].

Some research suggests that fictional narratives may be more effective for use in *bibliotherapy*, causing readers to empathize more with the characters and leading to better self-understanding and self-improvement [2].

Moreover, neuroscience reveals that storytelling influences brain chemistry, enhancing empathy and trust through the release of oxytocin and vasopressin [3]. This approach effectively enhances emotional experiences and trust, aiding in personal development and resilience [4].

4 Psychodrama and its Traits in Magic Shop

There are many ways to grasp the concept of *Magic Shop*. The first is understanding it as an in-depth training program with transformational practice, which will be discussed later in chapter *6.2 K-POP in Magic Shop*.

On the other hand, there is a possibility to apprehend it through the concept of *psychodrama*, which will be our primary interest, within this paper. *Magic Shop* is a practice used in *psychodrama* and group therapy in which participants create a space where they can "buy" something they already want, such as confidence or peace, from what they already have internally, such as anxiety or anger. In other words, this activity helps individuals explore their deepest passions, and the sacrifices needed to achieve them, while encouraging self-reflection and personal growth, with a possibility to solve conflicts in a safe, symbolic environment [5].

The term magic can be seen in society as something that carries supernatural power. *Magic Shop* is not an exception. Thus, it has a lot of forms and names: *Magic Shop* is our deep understanding of heart and brain in harmony. We often compare ourselves to others and hope we could be better than we are. Specific traits like social ability, patience and cleverness are examples that require time and practice. But it seems that *Magic Shop* is the key [6]. This method as a *psychodramatic strategy* can offer help to anybody through the use of fantasy [7].

In general, *psychodrama* is an experiential form of therapy, allowing those in treatment to explore issues through action methods (dramatic actions) [8]. This described approach, linked with *psychodrama*, was developed by Jacob Levy Moreno as a psychotherapeutic technique useful in working with patients during individual and group psychotherapy. This method offers significant changes through role-playing and dramatization, resulting in many benefits, such as insight, abreaction, acceptance of internal impulses, confrontation with the feelings of other people and training of alternative behaviors [9]. Whether we are talking about the first or second definition of *Magic Shop*, it can be a double-edged sword linked to maintaining one's own physiological and psychological well-being.

5 AI used in Therapeutic Spaces

AI chatbots are increasingly being used to enhance mental health care by offering real-time interactions that meet cognitive and emotional needs. These digital tools are part of a broader shift in communication, driven by the "computers-are-social-actors" paradigm, where AI significantly impacts how people engage with services [10].

In therapy, AI complements traditional methods by providing personalized interventions, making mental health support more accessible. Virtual environments facilitated by *AI* can create new opportunities for personal fulfilment and emotional connection [11].

Moreover, there is an overlap, because recent research by McAllister et al. explores the potential for *chatbots* to enhance *bibliotherapy* by supporting facilitators in mental health sessions. The study seeks to address gaps in existing literature by investigating how *chatbots* can be utilized to assist in the preparation and delivery of *bibliotherapy* [12].

In addition, in response to the high potential of technology, interviews with *bibliotherapy* facilitators have been conducted, followed by thematic analysis, to identify suitable tasks for the *chatbot*, aiding facilitators rather than directly evaluating the impact on participants of *bibliotherapy*.

This integration represents a major step towards a more comprehensive and accessible mental health framework.

6 K-POP as Multidimensional Tool

Although *Korean pop*, generally known as *K-pop*, seems to only overlap with music therapy, due to its main impact field, *K-pop* may also serve as a useful case application for *bibliotherapy, the Magic Shop* technique, and *AI* tools.

Some *K-pop* groups participate in transmedia story worlds and lyrical concepts that go far beyond "unrequited love" themes, touching the human psyche more deeply. Additionally, merging this with technology platforms like "Weverse" or "Bubble for JYPnation ", not to mention fabricated interactions through apps like "Replika", "Mydol", etc., fans have never felt closer and more bonded to their idols, who are revered with boundless support and understanding.

6.1 K-POP in Bibliotherapy

Many *K-pop* groups rely on some form of storytelling, but some take it a step further. In particular, *K-pop group BTS's* "BTS Universe" *(BU)*, functions as a multidimensional tool for emotional and psychological engagement. In *bibliotherapy, BTS's* books, *The Most Beautiful Moment in Life: The Notes*, provide a unique narrative that facilitates self-reflection and emotional exploration. These notes, embedded within the group's *Love Yourself* albums, as well as two books published by *BTS's* label, offer fans a form of therapeutic engagement by inviting them to interpret and relate to the fictional world, which can mirror personal experiences and foster emotional processing [13].

This can be particularly striking when we take into account individual emotional overload with a long-term inability to

restart one's own coping mechanism to underlie qualitative functioning in everyday life.

Preliminary research has suggested that the stories embedded in *K-pop* can have a positive impact on fans' ability to cope with challenges and heal. One survey found that *97%* of fans (*n=2342*) agreed that *BTS's* music and lyrics were effective in this way. Additionally, *84%* agreed the storylines in *BTS's* concepts were effective, and *75%* agreed the *BU* storyline was effective [14].

These numbers suggest valid proof of audience engagement techniques in fiction, described by Donald Maass as presenting novelty, challenge, or aesthetic appeal to readers, which leads to better identification with the story, while figuring out solutions for the main character´s actions, reflecting in an individual's healing scheme [15].

6.2 K-POP in Magic Shop

There is no doubt that science plays a crucial role in our understanding of human beings, yet some phenomena, such as compassion, altruism and empathy, remain enigmatic. These concepts form the foundation of James Doty's work, particularly in his book *Into the Magic Shop: A Neurosurgeon's True Story of the Life-Changing Magic of Mindfulness and Compassion*, which inspired not only this paper but also the lyrics of the *K-pop group BTS's* song "Magic Shop". The song, much like Doty's book, is perceived to have a healing effect on many individuals, resonating deeply within a therapeutic framework. Doty is not only a renowned author but also a researcher who founded the Center for Compassion and Altruism Research and Education (CCARE) at Stanford University, which supports his desire to analyze the interaction between the mind and body in relation to the concept of *Magic Shop* [16].

6.3 K-POP in AI Chatbots

In the *K-pop* world, *AI* enhances fan interactions by fostering *parasocial relationships (PSI)*, a term that goes back to its roots in 1956 when it was defined as the illusion of a face-to-face friendship between audience members, along with the main factor of a one-sided relationship [17] with *idols* (Korean singers within *K-pop* industry). *Chatbots* like "ChatGPT", "Replica" or "Mydol" offer more personalized conversations, deepening the emotional connection fans feel with their favorite stars [18]. This can be particularly comforting for those dealing with anxiety or low self-esteem.

AI-driven *PSI* offers new avenues for addressing anxiety, providing a controlled environment for emotional exploration. While there are risks of maladaptive obsessions, the positive impact on psychological well-being is significant when managed carefully [19]. As *AI* continues to evolve, its role in supporting mental health in niche areas like *K-pop* will likely grow, offering innovative solutions to common challenges [20].

7 Relevance for Cognitive Science & Cognitive Behavioral Therapy

Understanding how the human brain reacts to situations, making individuals feel distressed has been already covered. Now, it is more than important to look for strategies to fight against it, apart from medicaments. Recognizing an individual's need to support one's prosperity and healing cognitive processes, interdisciplinary cognitive science offers an opportunity to merge concepts together that might bring new ways to deepen our knowledge.

Combining different approaches, such as *AI chatbots* using *Cognitive Behavioral Therapy (CBT)* with minimal *bibliotherapy* interventions, is slowly but steadily indicating that the *chatbots* are more effective in reducing symptoms of depression and anxiety [21], which is the primary desired effect.

Moreover, *fanship*, an individual's bond to their idols, plays a crucial role in enhancing happiness, self-esteem, and social connectedness, which pushes forward the application of social identity theory in the realm of *K-pop* fans and expands the psychological understanding of fandom and its extended therapeutic possibilities [22].

8 Findings

Combining *bibliotherapy*, the *Magic Shop* psychotherapeutic method and *AI* tools can offer a comprehensive mental health treatment model. *Bibliotherapy* provides cognitive and emotional benefits through literature and storytelling, the *Magic Shop* method engages clients in creative and transformative experiences, and *AI* tools ensure continuous support and accessibility (as shown in Figure 1).

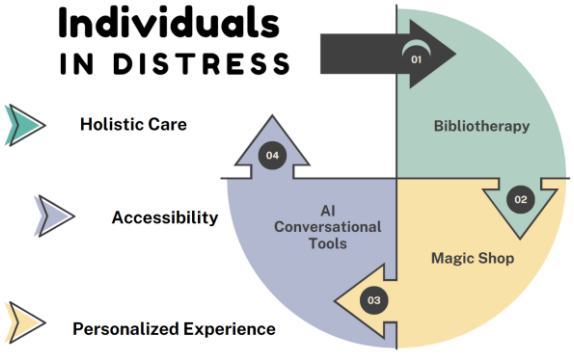

Figure 1: Infographic of Innovative Supporting Approaches

Note. Created with *Canva.com*

a. ***Holistic Care:*** *The union offers a multidisciplinary approach to mental health, addressing cognitive, emotional, and practical needs. By considering the whole individual, this approach promotes holistic healing and improves overall well-being.*

b. ***Accessibility****: AI tools streamline mental health services and provide immediate support, covering a gap to traditional treatments. This ensures that more individuals can access the help they need, regardless of location or financial barriers.*

c. ***Personalized Experience:*** *Integrated approaches enable tailored interventions that can be adapted to individual needs and preferences. This personal involvement improves the effectiveness of treatment, leading to the best results and a more satisfying treatment experience.*

Additionally, *K-pop* offers a valuable case application for this holistic program, given the rich story worlds and concepts combined with fans' love and attachment to their favorite idols, some of whom can be accessed through *AI* applications.

9 Study Limitations & Subsequent Research

Regarding the limitations of this paper, both authors are fully aware of the restrictive parameters linked to the exploratory case study, which was selected as a presented application. Therefore, the mentioned research gaps and possibilities of merging therapies have only an advisory nature with the need for subsequent research with possible future administration in professional-guided therapy sessions, as well as individual applications after undertaking a specialized training process provided by professionals in specialized facilities.

10 Conclusion

Unveiling how to provide the most appropriate care to those who need to overcome difficulties while restarting their coping mechanisms can be quite diverse and tricky. Understanding the individual treatment plan is the key. While previous research has been focused on single therapy treatment, nowadays there is a strong case for merging them. Encountering situations through the safe space of stories allows individuals to better understand actions and emotions, develop empathy and progress in their healing journeys. *Bibliotherapy* allows readers to internalize and adopt positive traits from characters they resonate with, while *psychodrama* facilitates deeper understanding and emotional growth through role-play and perspective-taking. In the realm of *AI chatbots*, this effect can be harnessed to create more empathetic and personalized interactions by mirroring users' language and emotional tone. With *K-pop's* use of *AI*, there is untapped potential for precision mental health care. Overall, these techniques underscore the importance of storytelling in fostering empathy, engagement, and therapeutic outcomes across these diverse fields.

Usability of intelligent assistive technology used by people with dementia and their caregivers

Klara Dečman
Cognitive Science, Occupational Therapy
University of Ljubljana & University of Vienna
Slovenia
kd1023@student.uni-lj.si, decmanklara@gmail.com

Abstract

Intelligent assistive technology with context-aware computing and artificial intelligence can be applied to assist a person with dementia and their caregivers with activities of daily living. This paper samples such technologies with a focus on current knowledge and practice concerning usability. We used a scoping study to address the objectives of the research. Our findings indicate that despite the importance of technology customization to individuals' needs and capabilities it is not commonly addressed in the literature. Furthermore, while researchers are aware of the concepts and aims of evaluating the usability of technology, they seem to face difficulties in assessing them.

Keywords

Activities of daily living, cognitive assistance, dementia, evaluation of usability, family caregivers, human-centered design, scoping survey, user experience

1 Introduction

Dementia is a neurocognitive disorder, typically chronic and progressive, characterized by impairments in cognitive functions such as memory, attention, orientation, and language [1, 2] to the extent that a *person with dementia* (PwD) is not able to independently complete *activities of daily living* (ADLs) [3]. *Personal* (pADLs) refer to basic physical needs such as dressing, toileting, bathing, and eating, while *instrumental* (iADLs) are essential for living independently in the community, such as preparing food, taking medication, and doing laundry [4]. The ICD-11 [1] identifies three *degrees of severity* of any type of dementia. In the *mild stage*, a PwD may live independently but requires supervision and/or support with iADLs, such as locating everyday objects, and handling finances. In the *moderate stage*, PwDs require support to function outside their home environment. They can accomplish only simple household tasks and experience difficulties with completing pADLs. In the *severe stage*, memory impairment becomes profound, though it varies by etiology. PwDs are fully dependent on others for pADLs and they often experience total disorientation in time and place.

One of the most common diseases in old age, dementia is recognized as one of the most costly and burdensome health conditions [2]. Statistics suggest that the growing global population of older adults diagnosed with dementia reached 44.4 million worldwide in 2013, with projections indicating an increase up to 135.5 million by 2050. Concern over the limited availability of family and professional caregivers for this rapidly growing population is intensifying (ibid.). As the population ages, the number of potential caregivers decreases, and those available often lack the key skills to provide the necessary level of care [5]. Furthermore, as family caregivers become more involved while struggling to balance other familial and social roles and responsibilities, they often experience negative consequences on their health, such as burden, anxiety, depression, isolation, and sleep deprivation [6]. Technological innovation, including advances in communications, robotics, and sensors, are perceived as promising to tackle these challenges [5]. Specifically, *assistive technology* (AT) refers to a broad range of devices and systems designed to maintain or enhance an individual's functioning related to cognition, communication, hearing, mobility, self-care and thereby promoting their health, well-being, inclusion, and participation [7]. AT is not designed to perform tasks on behalf of the user, but are specifically designed to monitor the activities of cognitively impaired users and provide appropriate assistance, thereby enhancing the likelihood of achieving desired behavioral outcomes [8]. A specific category of AT, *cognitive orthotics* [9] or *cognitive assistive technology* [10] is designed to assist with *cognitive* tasks. For instance, AT is employed to remind PwD to take medication or that their family member is visiting them next day [9, 10]. PwDs and their caregivers routinely use low-tech aids, such as medication pill organizers, schedules, and notes. They are being offered high-tech aids, such as *intelligent assistive technology* (IAT) that employs artificial intelligence to assess whether and when an appropriate reminder or procedural guidance is necessary for task completion [11, 12]. Additionally, IAT should be *contextually aware*: able to examine its environment, react to changes within it, and thus provide help *when needed* [11].

Human factors and *ergonomics* are scientific disciplines focused on studying the interactions between humans and other components of socio-technical systems [13]. The aim of designing such products and systems is to minimize human error and enhance human efficiency. One attempt at managing human factors analysis and human errors is through the development and deployment of measurement standards such as the *Human Readiness Levels* (HRL) scale (ibid.). HRL complements and

supplements the *Technology Readiness Level* (TRL) scale, which captures the maturity of technology before and after its integration into a developing system [13, 14]: HRL emphasizes the readiness to develop technology for effective and safe *human* use, and it should capture human-related features of technology development [14]. Similarly to TRL, HRL scale is divided to nine stages: *basic research and development* of principles, concepts, and the application of human characteristics, performance, and behavior, along with guidelines incorporating human-centered requirements to enhance human performance and human-technology interactions (HRL 1…3); development and assessment of user interface design concepts and prototype simulations in *laboratory and real-world environments* (HRL 4…6); full-scale testing, verification, and deployment in an *operational environment* with representative users and system hardware and software (HRL 7… 8); and the final stage, where the system is actively used in the *operational environment* with systematic monitoring of human-system performance (HRL 9) [14]. HRL is closely linked to *user-centered design*, a framework for the design and development of new products or the assessment and evaluation of existing products that explicitly considers potential users' needs, wishes, and subjectively perceived limitations of the IAT [5, 9, 12].

Some key definitions from the ISO standard on ergonomics of human-system interaction [15] read: "3.13 *usability*: extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use. … 3.3 *effectiveness*: accuracy and completeness with which users achieve specified goals. … 3.4 *efficiency:* resources used in relation to the results achieved. Typical resources include time, human effort, costs, and materials." Further important aspects of usability include *user satisfaction*, the "extent to which the user's responses resulting from use meet the user's needs and expectations; how *accessible* a product, system, service, or environment is to individuals with diverse needs, characteristics, and capabilities is another element of usability". As examples of differences in terminology, see e.g. [16], where *utility* refers to whether the design provides features that users *need* and *usefulness* covers how pleasant and easy to use technology is (usability) and whether it does what users need (utility).

2 Methodology

This short survey covers only some of the findings of my ongoing more comprehensive review of topical IATs [17]. For this survey, the following research questions to explicate the coverage of *usability* will be addressed:

1. What is the maturity of IAT for human use (= its HRL)?
2. (How) do the developers take the *progression* of the disease into account?
3. How exactly is technology being assistive?
4. How is the usefulness and usability of the technology evaluated (if at all)?

Our scoping study maps key concepts, main sources, and types of evidence available for the domain targeted. For methodological transparency, we followed the PRISMA-ScS checklist [18]. Our search combines electronic database platforms (APA PsycInfo, Google Scholar, IEEEXplore, ProQuest, PubMed, Scopus, Web of Science, as well as the digital library facilities of the Universities of Vienna and Ljubljana) with hand searches of electronic journals and literature identified through literature readings. For this survey, we included original articles, conference proceedings, and PhD thesis; written in English; and published "within the last decade" (i.e., since 2013). To be covered, IATs further had to meet the following *inclusion* criteria: direct applicability to dementia care, focus on assisting with ADLs, PwD, and/or family caregiver as a user. We *excluded* IATs developed for the support of other (if related) disabilities, such as traumatic brain injuries; that could only be used by professional caregivers.

3 Findings

We illustrate our findings for each research question using the technologies: COACH [10, 11] and AWash [19] (targeted ADL: handwashing); DRESS [20] (getting dressed); ToiletHelp [21], (using a water toilet); and Smart Toothbrush [22] (brushing teeth). The pADLs supported by these IATs must be performed regularly to maintain the person's independence, health, and overall well-being. As dementia progresses, PwD becomes increasingly dependent on others to complete ADLs, affecting their family caregiver and society (cf. section 1).

3.1 Human Readiness Levels

We assigned aggregated HRL scores according to the groups introduced in section 1, with most of the surveyed technologies ranking at HRL 7…8: COACH, AWash, and ToiletHelp. This likely results from our choice of targeted content, as we aimed to focus on IATs close to HRL 9. We mapped DRESS and Smart Toothbrush to the HRL range 4…6, as the first is about developing and evaluating a prototype in preparation for in-home trials with PwDs, while for the second only preliminary laboratory testing was conducted with healthy individuals.

3.2 Different stages of Dementia

The IATs selected for this article are intended to provide targeted assistance for different stages of dementia. ToiletHelp is aimed to be used by PwD in the mild stage of dementia, COACH in moderate to severe stage, DRESS and Smart Toothbrush in severe stage, while for AWash we have not found any explicitly targeted stage of dementia. We found no evidence of technologies taking into account individual differences and needs of PwDs and their caregiver, consequently, we were not able to find such technology that would be able to *adapt* according to the actual severity of dementia as disease progresses (cf. section 3.3). Such *customization* is needed as cognitive functions progressively deteriorate, with fluctuations in rating occurring throughout the day or as the system would be used over periods ranging from weeks to months or even years [20, 21].

3.3 Notions of Assistance

Assistance involves *interacting*, with *prompting* being an interaction strategy that has become widely popular also in the context of IATs. Within our target domain, we found *audio* prompts to be most common as they are part of COACH, AWash, DRESS, and Smart Toothbrush. Such assistance should guide

PwD through the sequential steps of the activity by pre-recorded voice commands. *Visual* prompts include *videos* of steps of activities (COACH); *pictures* of correct clothing items (DRESS); use of different *lights* to attract attention to the appropriate use of an object (DRESS, Smart Toothbrush); and *texts* with instructions (ToiletHelp). DRESS consists of *motivational* prompts in the form of songs or videos favored by the PwD are meant for when a PwD should get stuck in an activity, and are configured by the family caregiver. COACH has options for *increasing levels of support*: low-guidance and high-guidance verbal prompts, video demonstrations, or placing a call to the caregiver. DRESS offers the choice of *continuous* mode, which includes chronological directions across all steps of an activity, and *independent* mode, in which no audio prompts are provided while the PwD is donning a shirt, and the caregiver should receive text messages on their device either when help is needed or dressing is completed. Nominal assistance provided by ToiletHelp consists of acknowledgment messages displayed to reassure the users they have completed every step of the activity; when the need is recognized, instructions are repeated. If a user should still fail, an alert informs the caregiver the PwD is having trouble, along with a reassurance message being displayed to the PwD.

The IATs we identified can help guide PwD through activities, but it is crucial to tailor such assistance to individual needs and adjust it as dementia progresses [20]. While there are cases where differing/increasing levels of assistance are provided by IATs [10, 11], such adjustment is not commonly documented in the literature. Despite its importance, our research indicates that there is also a lack of consistency in the terminology used to describe the adjustment of IATs to individual needs (e.g. customization, personalization, adjustment, adaptation).

3.4 Usability

The resources we analyzed indicate a dearth of commonly used standardized usability tests; out of the systems surveyed, only Awash was assessed using the System Usability Scale (SUS) questionnaire [23]. Instead, information about the usability of IATs is often gathered through user interviews [10, 11, 20, 21], observation, and performance testing [10, 11, 19, 21, 22].

In terms of *effectiveness*, COACH and AWash users were able to independently complete more steps of activity and engage less with caregivers while using IAT. Regarding *efficiency*, the developers of the Smart Toothbrush have estimated its battery life, while those of DRESS considered the final product's cost. In terms of *user satisfaction*, caregivers noted several benefits of DRESS, including validation of memory loss, empowerment of PwD, promoting privacy and dignity, and providing caregiver respite. ToiletHelp was reported to increase PwD's autonomy, boost self-esteem and dignity, and reduce the burden on caregivers. Participants rated AWash with a positive user experience. On the other hand, difficulties in using the technology were due to varying stages of dementia, visual and sensory perception issues, the need to change routines, and *affordability* issues [20]. Users expressed dissatisfaction with long delays between tasks and the frequency of prompts [10, 11, 22], while overlapping video and verbal messages used in ToiletHelp caused distraction. The acceptance of IAT largely depends on its *utility* and its unobtrusiveness, which can encourage more consistent use.

The current understanding of usability reflected in the literature indicates that even when researchers are aware of the related concepts and terminology and aim to assess them, they have difficulties in doing so with unified questionnaires or standardized testing procedures.

4 Relevance of Cognitive Science

The goal of the inter-disciplinarity of Cognitive Science is to address the question of *how does the mind work* – why we do the things we do, think the way we think, and how we perceive the world around us – by trying to understand and explain underlying mental processes and mechanisms of human behavior from the point of view of each discipline [24]. In user interfaces, *computational models of human behavior* are used to describe and capture our understanding of typical user actions, predict future actions, and guide users toward improving their actions [25]. These computations are typically based on *internal symbolic knowledge representations*, allowing a cognitive agent to manipulate symbols to gain information about the external world and determine how to act effectively – plan and perform actions, and achieve specific goals [26]. Evolutionary psychologists view the information processing architecture of the brain to consist of *adaptive problem-solving systems* that use information to adaptively regulate physiology and behavior. In this perspective, attention, learning, emotion, and motivation all play key roles in minds work and how we respond to our environments [27]. In particular, motivation can *guide* cognitive processes: When a PwD becomes fatigued, their motivation to continue activities declines. IATs can help by providing motivational prompts, such as favorite music or videos, which evoke emotional memories. This is but an example of how, cognitive science provides crucial insights into how users perceive, process, and interact with technology and consequently affects both, the improvement of designs and testing of usability and usefulness. It is a "bridge" between applied artificial intelligence and user experience.

One important objective of applied artificial intelligence is the development of cognitive orthotics, designed to *enhance* and *expand the user's cognitive abilities* [28]. It is not about technology imitating human abilities, but rather *extending* them. The key focus is the importance of creating systems that combine human and machine components in a way that maximizes their individual strengths taking into account ethics. To design successful cognitive orthotics, *interdisciplinary* teams are needed to unite relevant knowledge and perspectives of professionals (such as computer scientists, engineers, physicians, cognitive psychologists, and neuroscientists) together with stakeholders and users of technology (ibid.).

5 Limitations and Future Work

As technology advances rapidly, future research should explore a wider range of IATs using novel modalities and supporting more diverse ADLs. This limited study cannot form generalized statements about IAT usability for PwD and caregivers, as

comparing specific ADLs is challenging due to variations in particular activity structure, cultural contexts, and dementia stages. We focused on a small subset of IATs addressing some pADLs, excluding those covering iADLs and multiple ADLs. [17] takes a step in this direction.

6 Conclusion

Dementia is becoming increasingly prevalent, posing a major societal, economic, and global health challenge. While extending the duration of PwD's stay in their private homes may be seen to help alleviate the strain on institutional settings, it in turn places a significant burden on family caregivers. While IATs are intended to enhance the independence of PwD and reduce the caregiver's burden, our literature review efforts suggest that usability aspects are not systematically assessed. This gap is also linked to current HRLs, which indicate that existing IATs are not fit for deployed use by PwD. Moreover, we find that IAT is often not designed to adapt to the progression of the disease, affecting its utility and usability. Heavy terminology such as *intelligent assistance* appears to be employed all too easily. Furthermore, practice in assessing and reporting usability appears to leave significant room for improvement.

Acknowledgments

I would like to express my gratitude to the University of Ljubljana and the University of Vienna for allowing me to choose a Master's thesis topic of personal and professional importance. I am particularly thankful to my supervisor Univ.-Lektor, Dipl.-Ing., Dr. Paolo Petta, for your guidance and the opportunity to learn from you.

ABSTRACT

The influence of Goodhart's law to the development of Open Science is discussed. Science Citation Index (SCI) and Open Access (OA) are important steps in the path from Science to Open Science (OS). The main conclusion is that flawed openness replaced quality in Open Science.

KEYWORDS

Open Science, Open Access, Article Processing Charges, Goodhart's Law, Free Journal Network

1 FROM SCIENCE TOWARDS OPEN SCIENCE

1.1 Science

Traditionally, scientists disseminated their findings by publishing their results in scientific journals. This is a key mechanism for knowledge transfer among scholars and therefore an important subject of cognitive science. In the old days, the process of writing a scientific paper was completely different. The author had to type the paper on a typewriter leaving spaces for handwritten greek letters, symbols and formulae. With the advent of copying machines only cumbersome paper "cut-and-paste" method was available. Smaller misprints were overtyped whilst larger corrections required replacing whole pages. Professional typists, not available for everyone, could speed up the process. Manuscripts were sent for publication by ordinary mail in several iterations, depending on the referees' requests.

Rise of technology quickly brought up big changes. The introduction of personal computers replaced typewriters by keyboards and drastically enlarged the population of those who were able to compose texts on a computer and simple editors introduced cut-and-past method of writing. Specialised software for producing high-quality scientific drawings and diagrams enabled publishers to request camera-ready manuscripts from the authors. Authors no longer focused only on the subject of their work but also on the look it will have when printed.

1.2 Characteristics of Classical Publishing Model

Classical publishing model was robust and healthy. It was free for authors. Certain journals were even paying author fees. Surprisingly, it was (almost) free for readers via libraries of public universities.

Main players involve authors, editors, referees, publishers, libraries, readers, universities, learned societies, funding agencies and taxpayers.

Publishing within classical publishing model was time consuming and required efforts from all parties. This somehow prevented the inflation and hyper-production of papers.

The model was mainly "subscription model" where articles were available in printed volumes of a journal. University and departmental libraries subscribed to major journals, covering selected fields of science. The contents of earlier volumes were available to library users. Most libraries were open to local community and also to visiting researchers. Several learned societies, universities and institutes published their own journals, associated with a given library and used them for exchange purposes. Instead of paying subscription to a similar journal they would simply exchange the journals. In this way a library was able to save money to subscribe to journals that were not available for exchange. This was an important way for wealthy western scientists to help scientists from Eastern block and third world countries. Later the revenue from scientific publishing was one of the main sources of income of major learned societies. Unfortunately, by acquisitions and mergers eventually a very small number of huge multinational publishers emerged. These publishing houses control the field of scientific publishing.

1.3 Transition to digital

The advancement of technology, in particular ICT (Information and Communication Technology), in the second half of the twentieth century with the transition from analog to digital completely transformed the process of scientific publishing.

The costs of all stages of publishing decreased. More and more work was transferred from publisher – printer to author. Publishing a paper became easy and inexpensive. The number of scientific journals started to grow even more rapidly.

Surprisingly, major publishers did not lower the cost of subscription to their journals. On the contrary, they started to bundle journals. If a library wanted to continue subscription to a journal it had to subscribe to the whole bundle of journals, many of which it had no interest in.

When papers became available in a pdf form, the need for printed versions decreased. This also meant there was no way to prevent an unauthorised access to the paper. The first electronic journals appeared.

There is a big difference between subscription to printed journal and electronic journals. Old volumes of printed journals remain in the library and are available to anyone having access to the library. On the other hand, volumes of electronic journals remain with the publisher who may deny access to the paid volumes after the subscription runs out.

Permission to make digital or hard copies of part or all of this work for personal or classroom use is granted without fee provided that copies are not made or distributed for profit or commercial advantage and that copies bear this notice and the full citation on the first page. Copyrights for third-party components of this work must be honored. For all other uses, contact the owner/author(s).

2 GROWTH OF SCIENTIFIC PRODUCTION; SHIFT OF GOALS

In the past century we experience tremendous growth of published scientific works. There are several factors contributing to this phenomenon.

2.1 Publish or Perish

"Publish or perish" is an aphorism describing the pressure to publish academic work in order to succeed in an academic career. It first appeared already in the first half of the twentieth century. For a long time the PhD was a sufficient proof of academic qualification. It was not unusual that the PhD Thesis was the greatest scientific achievement of a scholar. Unfortunately, the growth in the number of universities and scientists led to inflation of PhDs. Some scholars would simply stop doing research when hired. Employers began requesting a constant flux of publications as a proof of scientist's devotion to research. Those who were unable to maintain high publication rate would be discouraged to stay in academia. And quantity became a proxy for quality.

2.2 Quality control

Ever since scientific journals appeared in seventeenth century, the quality of publications was in the hands of scientists using the system of peer review. This was natural since everybody involved: authors, editors, referees and readers were scientists.

With the growth of number of journals it became clear that not all journals apply the same standards for accepting a paper for publication. Obviously there was a problem of quality control.

In mathematics there was a secondary system in place. It started in Germany before WWII. Eventually, three refereeing journals were established, one in the Soviet Union, one in the USA and one in Germany (nowadays at the European Mathematical Society). If a review of a paper does not appear in one of those refereeing journals, the paper is likely not to be interesting for mathematicians.

For science in general there is a similar publication, called Current Contents.

2.3 Citation index

If we know for each paper the list of papers it cites, we can also produce the inverse index, i.e. the list of papers that cite a given paper. Such index is called citation index. In 1964 Eugene Garfield conceived the Science Citation Index (SCI) [3]. Using citation index one can easily detect most follow-ups to a paper covering a topic of scientist's interest. Clearly there are certain limitations. One has to select a collection of journals from where papers and their references are included. This may introduce some bias.

2.4 Impact

On the other hand, if the database is stored in a computer one can easily perform some statistics. For instance one can store with each paper the number of its citations. One can also compute how many citations each author has. This may, again, help the scientist to select the papers to look-up and authors to follow.

However, it also leads to all kind of rankings. Citation indices became very useful not only to scientists but also to their employers and funding bodies. Instead of comparing the added knowledge of someone's research, it is "sufficient" to select the highest ranked candidate. Selection can be done by administrators or computers. No peer review is needed. The paradigm "Publish or Perish" was upgraded to "Be Cited or Perish".

3 BIBLIOMETRICS

With the Science Citation Index (SCI) a number of statistical measures were introduced that would help profiling an author, the work or the journal. The science of bibliometrics was born. It was later extended to scientometrics and ultimately to informetrics.

SCI introduced a number of measures, indicators or metrics, trying to capture certain properties of articles, authors and journals.

One such indicator is the *journal cited half-life*. It is the median article publication date for each journal citation during one calendar year. In general, the journal cited half-life is small for recent journals while it is large for older, well-established journals. On the other hand it depends, as any other indicator on the scientific field and the culture of publishing in that field. Finally, a large journal cited half-life indicates that publications in that journal remain relevant for a long time. Hence the new knowledge is persistent and not merely mundane. Nowadays, it would not be difficult to equip any bibliographic database with computation of journal journal cited half-life.

3.1 Journal Impact Factor

Notorious Impact Factor (IF) is a ratio between the number of citations in a given time period - usually a calendar year, to the articles, published in another time period - usually two calendar years before. Sometimes they present also 3-year or 5-year impact factors.

For some reasons a 2-year impact factor prevailed and became a standard. In certain sense a 2-year impact factor is complementary to a journal cited half-life. Definitely, a 2-year IF is not the best indicator for mathematics when compared with other sciences where citation culture is different. For instance, when 1756 SCIMAGO journals covering the subject area of Mathematics are ranked according to Cites/Docs. (2 year) for the year 2023, among the top 50 journals only one journal has Mathematics as the primary subject area.

3.2 Metrics and Ranking

Having different indicators for a set of journals is good. It gives a higher dimensional description of each journal. However, each indicator may be used for sorting and hence for ranking. There is a strong tendency to devise an indicator that would measure quality; an impossible task.

Never-the-less since early seventies the Impact Factor is considered by many a proxy for the quality of a journal. The false reasoning goes along the following lines:

- Outstanding scientists publish their work in high-quality journals.
- The work of outstanding scientists is frequently cited.
- High-quality journals have high impact factor.
- Wrong conclusion: Work published in a journal of high impact factor is of high quality.

3.3 Power law and related statistical laws

When plotting the distribution of ranked impact factors, one can observe the exponential decay. Impact factor $IF(r)$ of rank r journal is proportional to $1/r^{\alpha}$ for some constant α. This is known as the power law. Roughly speaking this means that there are only a few journals with high impact factor and there are

many journals with small impact factor. One way of stating this is that 20 percent of most cited journals receive 80 percent of citations; see [7]. Several of these laws were first observed in bibliometrics. However it is interesting to observe that these laws are universal and apply to a variety of unrelated situations, perhaps by choosing the right value of parameter α.

4 GOODHART'S LAW

British economist Charles Goodhart is credited with expressing the core idea of a law in a 1975 article on monetary policy in the United Kingdom. "When a measure becomes a target, it ceases to be a good measure"; see [4]. Another way of saying is "that once a metric is used as a basis for decision-making or control, it loses its reliability as an accurate measure".

The main rationale behind this law is adaptation or even gaming to improve one's rank. If high rank means high reward, it is plausible, that some people will do anything to improve their score for the given indicator. Each measure for assessment of researchers and journals became prone to Goodhart's Law.

4.1 Goodhart's Law and Bibliometrics

When the number of publications are counted, researchers will tend to split long papers and publish short bits and will thus increase the number of publications. Instead of publishing papers alone they may increase their output several times if more coauthors sign the same publications. There is no increase in quality of their output.

When the number of citations decide who is winning a grant, the number of citations soared. The authors started citing their own papers, even if citations were not needed. When self-citations ceased to count, friendly researchers helped each other with citations.

When the h-index was introduced, the key publications of potential PIs in a research group had to be cited.

Employers and funding bodies understood that blindly rewarding high production authors with large impact papers does not mean rewarding high-quality science as there was no problem in publishing papers in low-quality journals and getting many citations in such journals. On the contrary, in many cases those fabricating papers and citations easily outperformed best researches. That is why the quality of journal in which the paper was published became important; in practice this meant journals with high impact factors.

By Goodhart's law, predatory publishers flourished, multiplying their journals and boosting their impact factors.

Production of new knowledge ceased to be important. It is the impact of their work published in high-impact journals that counts.

There is a difference in Goodhart's law and other laws, used in bibliometrics. Goodhart's law involves time and decision while laws based on power law are based on rankings.

There are not many studies of Goodhart'sl law in bibliometrics. An exception is a comprehensive study reported in [2].

5 OPEN ACCESS A STEP TOWARDS OPEN SCIENCE

5.1 APC model

The idea that authors or their institutions should make financial contributions for their publications is not new. In the times of paper publications, the publisher would grant some, say 25 reprints. For ordering extra reprints it was not uncommon to charge the authors. Also, one could be charged for insisting that the figures be printed in colour. On the other hand, some prestigious journals, started requesting article processing charges (APC).

Employers and funding agencies soon recognised that if they want their scientists to publish in the journals with very high impact factor, they will have to cover the costs of APC. Some scientific disciplines such as mathematics declined this model. When judging whether to pay APC or to send a graduate student to an international workshop many mathematicians give precedence to student. However, the publishers realised that money could be presented as a proxy for quality and raised their prices.

5.2 Diamond- and Green Open Access

In the last decade of the twentieth century some of the first purely electronic journals appeared. For instance, *The Electronic Journal of Combinatorics (E-JC)* was funded in 1994. It was free for authors and readers. It is run by scholars and not by commercial publishers. This is nowadays called a *diamond open access*, with no cost for authors and no cost for readers. E-JC is a founding member of the Free Journal Network [9].

Even before that, in 1991, an e-print server *arXiv* was launched where preprints in some scientific disciplines may be uploaded. Nowadays, such posting of preprint before peer review is called *green open access*.

For a while it seemed that this model will force big publishers to lower the prices of their journals. In the battle between scientists and multinational commercial publishing houses, the scientist should have won. It was expected that governments will support scientists in the fight against greedy publishers; [10]. However, politics works in mysterious ways.

5.3 Budapest Open Access Initiative (BOAI)

In December 2001 there was a two-day conference, producing a declaration called Budapest Open Access Initiative. The declaration was launched in February 2002, having 16 original relatively unknown individual signatories. This initiative has been financed by Soros' private Open Society Institute with 3 200 000 USD. It is recognised as one of the major defining events of the open access movement, [8]. Up till now it has been signed by about 0.1% of world scientists.

5.4 Gold Open Access and APC

Gold Open Access requires the author to pay Article Processing Charges (APC) to keep article freely available to the reader. Currently a typical APC exceed 3000 EUR. This brings enormous profits to publishers. It is estimated that the costs per article should not exceed 1000 EUR.

Clearly, APC model is not viable if costs are indeed covered by the author. The author must find someone who will cover the costs of APC. This is an ideal model prone for corruption at all levels. In the APC model, money becomes a substitute for quality. and researchers must compete for money that will cover their publication costs.

The difference between Green and Diamond Open Access and Gold Open Access is huge. One can speak of two opposing concepts sharing the same name: Open Access.

6 IMPLEMENTATION OF OPEN SCIENCE

6.1 Recommendations, Declarations, ...

There are numerous mostly political papers, initiatives, recommendations, declarations, pushing for Open Access, Open Science, Open Research, etc. Due to limited space we mention only a few of them. For more information, see e.g. [1, 5].

While the OA has been launched bottom up by 16 individuals meeting in Budapest, backed up by 3.2 Million USD from Open Society Institute, OS is a political concept that is revolutionising Science from top to bottom. It seems it was first formally expressed by UNESCO in November 2021 in the UNESCO Recommendation on Open Science.

The concept has been embraced by European Commission that pushes it through Horizon Europe down to member states. For instance, Slovenia recently received 16 000 000 EUR for promoting OS. It appears this money does not go for science but for administration.

The Barcelona Declaration on Open Research Information emerged from a workshop with over 25 experts interested in changing the research landscape. The declaration that was signed on 24 April 2024 is a political statement of an unidentified *community*. The authors do not act as individuals and do not represent scientific community. They write: *... we, as organizations that carry out, fund and evaluate research, commit to the following ...".* The first out of four commitments is strong. *We will make openness the default for the research information we use and produce.* It leaves no room for science outside Open Science. While OA was at first optional, OS makes it mandatory.

6.2 Goodhart's Law and Open Science.

Since journal impact factor remains a measure, the number of journals and publishers keeps increasing. In general, neither OS, nor universities nor funding organisations address the problem of low-quality high-impact factor predatory journals. Several scientists lower ethical standards and publish their papers in expensive journals with mild or no refereeing. The costs are reimbursed by their employer or funding organization.

Ever since the number of publications became a measure, scientists tend to publish papers with partial solutions to the problem. The number of co-authors per paper keeps increasing. The number of published papers grows out of proportion.

After citations became a measure, the number of references per paper keeps increasing. Some prominent journals fight citation inflation by limiting the number of references a paper may have. Clearly, the references published by competing authors are first to go.

Since APC remains as a valid model in OS, all kinds of unethical practices emerge. In many cases, a ghost author, who did not contribute to the paper but may secure covering APC costs is added to the list of authors.

It is disturbing that the goal quality is absent in some documents on OS, such as the Barcelona Declaration. The quality is replaced by openness and Goodhart prevails. Scientists will adapt to new goals.

7 CONCLUSION AND SUGGESTIONS

OS has some serious flaws. The main concern of OS is that scientists financed from public funds are not allowed to profit from their work – but everybody else can.

OS is only open to those within the system. Independent critical scientists adhering to high ethical standards are left out. OS is concerned only with current and future publications. No pressure to commercial publishers to open archives of papers published previously under paywall and make them free for everyone. A large part of science remains closed to authors and readers that are unable to secure money.

Scientists no longer decide what is the quality of their work. They even have to pay private companies to tell them that. For instance, public employers and public funders base their decisions about the quality of candidates on data bought from private companies running services, such as WoS or Scopus.

There is a problem of citation culture among different scientific fields. For eaxample, if average scientists from a scientific field, say A with high h-index compete for money in another field, say B they may be ranked higher than the best scientists of the field B. This may have negative effect on the future of the field B.

There is no real need for repositories at every public institutions. One repository at the European level with several backups would suffice. Instead of creating jobs for scientists repositories create jobs for administration. Repositories of papers and data are not intended for individual scientists. It appears they are intended for the AI data-harvesting algorithms of private companies. This service again will be sold back to scientists.

One could say, that the OS is a model that diverts public money from scientists to administration and private companies.

The Consistency of the Research Field Data
A Case Study of Library and Information Science in Slovenia

Jan Pisanski
Faculty of Arts, University of Ljubljana, Aškerčeva 2
Ljubljana, Slovenia
jan.pisanski@ff.uni-lj.si

ABSTRACT

SICRIS (Slovenian Current Research Information System) provides a service listing top Slovenian researchers in a particular research field. In Web od Science (WOS) each journal is assigned one or more categories (research fields). When comparing these data for the research field of library and information science (LIS), we found that several of the top authors in the field according to SICRIS rarely or never published in the journals deemed to belong to LIS in Web of Science. Several other authors, who were not assigned the research field of LIS in SICRIS, were among the most published Slovenian authors in LIS in Web of Science. This is an indication that results of any analysis of LIS in Slovenia will depend greatly on the criterion/criteria used.

KEYWORDS

Bibliometric Analysis, Research Fields, Slovenia, Library and Information Science.

1 INTRODUCTION

As part of a project focusing on high-level bibliographic services, i.e. novel services based on existing bibliographic data, we intended to perform a domain analysis of library and information science (LIS) in Slovenia from a bibliometric perspective. This contribution describes the initial step that was simply intended to provide an overview of research and researchers but came up on several issues regarding assignment of research fields and yielded some interesting findings, particularly for establishing the scope of the research field in Slovenia and elsewhere, but also in view of providing better services to the users of academic bibliographic databases.

2 BACKGROUND

There is a lack of a bibliometric overview of information scientists and librarians in Slovenia and their works, collaborations etc. One of the reasons is the nature of the field(s) of library and information science, where sometimes it is difficult to draw the distinction where the boundaries of the field are. On the other hand, relatively high-quality information on Slovenian researchers is stored in SICRIS (https://cris.cobiss.net/ecris/), the Slovenian current research information system, which provides multiple tools for basic bibliometric analysis.

Other studies have focused on the research fields in Slovenia (e.g., [1], [6], [8]), however at a more general level, not specifically for LIS and without mention of the issues related to research fields discussed herein, whereas [2] discusses among other things the mapping of WOS categories to the fields of science, used in SICRIS. Also see [2] for a brief history and overview of various mappings of fields of science/research fields.

While we were primarily interested in using bibliometric data for representation of a particular research field, this can then also be commonly used for evaluation of research. There are two main approaches: expert evaluation and bibliometric analysis. While expert evaluation is more traditional and qualitative, bibliometric analysis is quantitive in its nature. However, both of them have their downsides. For discussion on trustworthiness of experts, see e.g. [4]. Amongst others, Leiden Manifesto [5] points to dangers of using bibliometric data without closely examining the context. It suggests various indicators should be used when evaluating researchers and their work and that bibliographic analysis should support expert evaluation.

3 RESEARCH

While there are several different ways to approach the extent of publication on library and information science in Slovenia, we looked at the publications in Web of Science (WOS). This was done with intention to identify the most prominent works and authors, as journals indexed in WOS go through a rigorous process. However, this also means that we omitted from analysis all other publications, including papers published in Slovenian language journals.

Although it may not have the same coverage of social sciences, for this kind of insight WOS compares favourably to similar services, such as SCOPUS and Google Scholar, as it allows searching based on WOS Categories field which represents the subject categories/research fields of the journals [7]. It has to be noted that the WOS Categories field provides general information about the thematic nature of the journal rather than each particular paper. However, this is still the easiest way to get a quick overview of a research field, as all of the subject related data pertaining to individual papers in WOS describes the thematic nature of the papers in higher granularity. Each journal in WOS can be assigned one or more subject categories.

In April 2024, we performed a search in WOS Core Collection for publications where Address field included »Slovenia« and the value in the WOS Categories field was »Information Science & Library Science«. We did not limit the search to any particular time period, which means that the more experienced authors were more likely to be on the list. Also, we did not limit the results to particular types of publications (e.g. articles), since the "linked records" categorization in SICRIS, which we used in comparison, also does not limit this. However, even if we did, the situation regarding top authors would still be similar. Since Address was limited to Slovenia, the list excludes Slovenian authors who published research while working in other countries and may also be missing authors with otherwise faulty Address data.

Table 1: Top 10 Slovenian authors in SICRIS, their research fields, number of established links to WOS publications in SICRIS and number of publications with LIS as WOS Category

Author	Research field 1	Research field 2	WOS	LIS	fraction
A	Information science and librarianship	Interdisciplinary research	89	0	0.0000
B	Administrative and organisational sciences	Information science and librarianship	55	2	0.0364
C	Information science and librarianship		55	47	0.8545
D	Economics	Information science and librarianship	53	14	0.2641
E	Computer science and informatics	Information science and librarianship	39	0	0.0000
F	Information science and librarianship	Plant production	33	17	0.5152
G	Information science and librarianship		31	29	0,9355
H	Information science and librarianship		24	2	0.0833
I	Information science and librarianship	Economics	24	3	0.1250
J	Information science and librarianship		21	18	0.8571

In SICRIS each researcher can be assigned up to two research fields, according to the ARIS (Slovenian Research and Innovation Agency) categorization, which is "roughly harmonized with the Field of Science and Technology Classification in the Frascati Manual (OECD)" [1]. There are different levels of categorization with the first level representing science, the second level representing field and the third level representing subfield. For instance, Information science and librarianship is deemed as a field belonging to social sciences with no further subfields. On the other hand, Economics also is a field of Social sciences, but it has subfields, such as Business sciences. Authors may be assigned a certain research field, even if it has subfields, or a certain subfield.

Among several features, SICRIS provides a higher-level service (https://cris.cobiss.net/ecris/si/en/top/researcher) where a user can look up most prominent Slovenian authors in a specific research field based on different indicators (e.g. number of linked records and citations in WOS and SCOPUS, h-index, other indicators linked to local evaluation practices). While this is not necessarily the only tool a user of SICRIS can use to get an overview of researchers in a research field, it is certainly the quickest and easiest to use.

Compared to some other research fields, where it is harder to find the equivalents in both of the databases, LIS has the advantage of being relatively straightforward. While the names used for the research field in the two systems slightly differ (»Information science and librarianship« in SICRIS; »information science and library science« in WOS), at least the core of the two subject categories should be the same.

While the actual ranking of LIS authors in SICRIS does vary slightly according to the indicator chosen (i. e. number of works in WOS and SCOPUS, number of citations, etc.) there is a core group of authors that occupies top places for several categories. Table 1 shows the top 10 authors based on the number of linked records in WOS according to SICRIS. In the table each author is represented with a letter of the alphabet for anonymity.

When comparing the data of LIS authors in WOS, whose address is in Slovenia (Table 2) and, the list of most prominent authors in LIS in Slovenia based on number of publications in WOS as provided by SICRIS (Table 1), we found a relatively large discrepancy. As seen in Table 1, half of the top 10 authors in LIS, as provided by SICRIS, had less than half of their works published in LIS journals, as indexed by WOS. In fact, for all five of these authors the proportion is less than one third.

There are several reasons for this phenomenon. In the SICRIS top 10 list, two prominent authors, marked in Table 1 as B and H, published a majority of their works in different fields, confusingly not explicitly named in SICRIS, before clearly switching their research interest to LIS. For some others their area of expertise is on the boundaries of LIS, although, what constitutes LIS can be debated. For example, two of the top 10 authors (A and E), including the top Slovenian author in LIS according to SICRIS, do not have a single work published in what WOS considers to be LIS journals. In the case of author A, their second research field, Interdisciplinary research, provides a better understanding on the nature of their publications.

According to the well-known Bradford's law [3] there are going to be some works published in journals that may not appear to be particularly relevant to a particular topic or research field. For instance, [2] found such distribution for Slovenian agriculture research group publication. However, there is still the question of whether such a list of top authors represents the LIS research field well.

It has to be noted that the results were similar even if we used other criteria in SICRIS. For example, the top 10 authors by number of citations in WOS are the same, only the order changes slightly. Also, the list of the top 10 authors by number of connected records in SCOPUS has two authors that do not appear in Table 1, neither of whom again had more than 2 works published in LIS journals, according to WOS.

To further complicate the matters in terms of transparency of data, SICRIS user interface only lists the author's first research field, in the top authors lists, which can be confusing to a novice user, as it may appear that some of the top authors do not belong to said field. In fact, many of the first year students of LIS at the University of Ljubljana skipped such authors, when asked to provide a list of top authors in the LIS field, based on SICRIS data/user interface.

Another issue that came up was that one of the top ten researchers is a foreign citizen with an ARIS researcher number having mostly worked outside of Slovenia. While this certainly reflects the international nature of science, it may not accurately reflect the state of LIS research in Slovenia. However, this issue is not particular to LIS.

On the other hand, there was also a notable group of authors that was not assigned to the research field of LIS in SICRIS, whose works appeared relatively frequently in LIS journals in WOS. Several new authors appeared in the top 10 list, if we only looked at the data on publications in WOS. Two of those, marked here

Table 2: Top 10 Slovenian authors by the number of publications in the WOS Category Information Science & Library Science journals and their assigned research fields in SICRIS

Author	LIS	Research field 1	Research field 2
C	47	Information science and librarianship	
G	29	Information science and librarianship	
J	18	Information science and librarianship	
F	17	Information science and librarianship	Plant production
K	16	Economics	Computer science and informatics
L	15	Mathematics	Computer intensive methods and applications
M	14	Information science and librarianship	
D	14	Economics	Information science and librarianship
N	13	Computer science and informatics	
O	13	Information science and librarianship	

as M and O, are authors whose field is declared in SICRIS to be LIS. But there are also three authors who do not have LIS named among their up to two research fields in SICRIS. Author here marked as K mainly worked in bibliometrics, which was also the LIS topic covered by author L, while author N mostly wrote on the topic of business intelligence. Such instances are not isolated, as several other authors who do not have LIS as a stated research field in SICRIS just missed the top 10 list.

4 DISCUSSION

While this is a brief look into a relatively small slice of two databases, SICRIS would benefit from a recognition of the issue. The simplest solution would be to provide a clear explanation on the nature of the data provided, when viewing top author lists by research field. Alternatively, additional services could be provided, based on other subject related data, such as WOS Categories or even keywords [7]. Ideally, services based on Bradford distribution would be provided.

The appropriateness of both the scope and designation of SICRIS research fields of authors and the WOS Categories can be debated. Their assignation procedures would benefit from greater transparency.

There is the issue of assignment of up to two research fields per author in SICRIS, as this does not necessarily accurately represent the involvement of each individual researcher. In our relatively small case study of LIS we found several authors whose assigned research fields could be viewed as misrepresented.

While research today is generally multidisciplinary and some researchers can shift their area of interest in research from one research field to another during their career due to various reasons, this ought to be reflected in any lists of researchers from a particular research field.

Also, while well-established, WOS would benefit from a more transparent explanation of the nature of WOS Categories. Even then, there can at least be a discussion, whether some of the journals are assigned to the correct research fields.

Conversely, as there are authors that publish relatively frequently in LIS journals in WOS, but do not have the according research field associated with them in SICRIS, a list of such authors could help with a subject classification of authors that is more reflective of their production.

5 CONCLUSION

Our research indicates that any bibliometric analysis of the research field of LIS in Slovenia is bound to be influenced by the criterion/criteria chosen to represent the field, as even the very top authors by one criterion may not be considered to be working in the field by another.

Further research could establish whether the issues found in this pilot study exist in other research fields and for other data (e.g. different databases, different time periods). However, not all research fields in one database may have their exact equivalent in another database. Cognitive science, for example, is not considered to be its own research field neither in SICRIS nor in WOS.

Generally, we suggest providing a clear explanation of the topical nature of the work of each author, when providing list of top authors in a research field, Another possible solution is omission of authors, who have a relatively low percentage of works published in journals from a research field from lists of top authors in that field.

While bibliographic databases offering high-level services that bring to light otherwise "hidden" data are definitely welcome, users would benefit from indication of imprecise nature of data and/or additional services that would try to account for the imprecision.

To be or not to be… a Nahuatl language learning App. The long-term survival or discontinuation of indigenous language learning apps on the example of Nahuatl

Evelyn Fischer†
MeiCogSci Student
University of Vienna
Vienna Austria
evelyn.fischer@posteo.com

Abstract

Language learning apps for indigenous languages differ from the mainstream language apps in that they are not targeted at commercial success and might need to accommodate different linguistic and cultural aspects than the most learnt languages. The present paper considers the present and past Nahuatl language apps, some of which were discontinued, and asks what would be necessary for such apps to achieve long-term survival.

Keywords

Language learning, human-computer interaction, software usability, software translation, trends in software development

1 Introduction

The strong digitalization of modern life is bringing about big changes to the global and local societies. One of the results of the technological changes is the rapidly ongoing globalization, and one of the mechanisms of globalization is the shift of communities from languages with small numbers of speakers to a smaller number of global languages. In many countries with colonial history, this follows centuries of, at best, ignorance of, and at worst, active discrimination and eradication of the indigenous populations, their languages and their cultures.

The dominance of global languages is clearly seen on the Internet, where 80% of websites are written in just 8 of the estimated 7000 world´s languages [1]. The ascension to the digital realm is a challenging task and in 2013 [2] estimated that, at best, 5% of the world's languages will ascend to the digital world, and the rest will suffer a “digital language death”.

One of the ways a language can be present on the internet is by being the object of mobile learning apps. Mobile apps supporting the acquisition of minority and indigenous languages may differ from apps targeting global languages in that minority language learning apps would typically not be aiming at commercial success, would have lower budgets, or even be done on volunteer basis by smaller group of language activists.

http://doi.org/10.70314/is.2024.cog.6

In addition, by pure chance, many of the most learnt languages have less complex morphology than many minority languages, and the apps that were developed with more analytic languages in sight, such as English, are not easily fully extendable to Morphologically Rich Languages, such as isiZulu [3], Turkish [4] and Nahuatl.

In the following, the focus lies on Nahuatl, the Mexican indigenous language with the highest number of speakers, 1.5 million. Nahuatl is one of 68 indigenous Mexican languages, and despite its historical prestige remains endangered, a challenge it shares with virtually all indigenous American languages. Nahuatl language learning apps contribute not only to thwart its digital death, but also to increase its visibility and prestige, and to support the efforts of Nahuatl learners to become “new speakers” [5] of the language. The role of new speakers is described as “very important, often essential for language revitalization projects” by [6] who work directly with Nahua and other minority groups in Mexico.

2 Initiatives to Localize Software and Platforms in Minority Languages

The second decade of the 21st century was a witness of increased efforts to increase the visibility and presence of minority and indigenous languages in the digital sphere. These were often led by digital language activists and sometimes supported by the companies whose software was the focus of the projects. The present section describes some of the initiatives taken and discusses the long-term results of the work to promote indigenous languages. Particularly, it looks at whether the work of the activists resulted in a long-term inclusion of the relevant language in the software or platform that was the aim of their efforts.

The Mozilla Foundation, known for its web browser, Firefox, launched in 2012 the initiative “Native Mozilla” that aimed to localize the browser into many of America’s indigenous languages. 50 languages from 10 countries were targeted [7], many of which are spoken in Mexico, such as Ch’ol, Kaqchikel, K’iche’, Mixteco (2 varieties: of Mixtepec and of Yucuhiti), Nahuatl (2 varieties or, by other accounts, 2 closely related languages: Highland Puebla Nahuatl of Mexico and Nawat Pipil of El Salvador), P’urhépecha and Triqui [7, 8]. The translations are done via the collaborative translation platform Pontoon (https://pontoon.mozilla.org/). As part of the initiative, for example, a Hackathlon was organized in Oaxaca in 2018 with representatives of 15 languages [8].

However, the goal of providing translations into 50 American languages is far from achieved and, as of 30.09.2024, Firefox 115 was available only in three American Indigenous languages: Kaqchikel and Triqui spoken in Mexico and in the South American language Guarani [9]. The other languages are in various state of completion: Ixil (13%), Kichwa (0%), Miahuatlán Zapotec (14%), Mixtec of Mixtepec (9%) and of Yucuhiti (29%), Nahuat pipil (0%), Paipai (1%), P'urhepecha (9%) and Quechua (3%). The situation is slightly better for the mobile phone browser Firefox Focus, which is available in Aimara, Ixil, Kaqchikel, K'iche', Maya, Miahuatlán Zapotec, Mixtec of Mixtepec and of Yucuhiti, Nahuat pipil, Navajo, Paipai, P'urhepecha, Quechua, Tének and Triqui [7, 10].

There were also attempts to localize the social media platform Facebook (https://www.facebook.com) into minority and indigenous languages. In 2012, the official Facebook translation platform (https://www.facebook.com/translations/), where users could add and vote on the accuracy of volunteer translations, had partial translations in about 100 languages, including Cherokee [11]. However, frustrated with the slow progress, Manuel Neskie made a browser overlay that allowed the translation of Facebook menu into Secwepemctsín directly in the user´s browser [11], which was later extended to many other languages, including Nawat [12] spoken in El Salvador. In 2015, a group of activists translated 24 000 words into Aymara and submitted it to Facebook for revision [13]. However, as of 31.08.2024, same as on 07.04.2019 [14], only three indigenous American languages were available for menus on Facebook: Cherokee, Inuktitut and Inupiaq, and the Facebook Translation App appears to have been discontinued.

A similar fate was met by the attempts to increase the number of languages offered on the Duolingo language learning platform (https://es.duolingo.com/). As of 10.06.2024, two indigenous languages are available on Duolingo: Hawaiian and Navajo [15]. However, previously also Guarani must have been available on the app, as evidenced by the surprise some users expressed at its sudden lack [16, 17]. The course is still available on the website version as of 31.08.2024 [18]. Between 2013 [19] and 2021 [20] new courses in development were stored in the Duolingo Incubator, where the users themselves could contribute to adding new languages to Duolingo. Indigenous languages such as Yucatec Maya and K'iche' were present on the Incubator and Duolingo itself credits the volunteers for helping to make, among others, the Navajo and Hawaiian language course [21]. However, Incubator was discontinued in 2021.

As we have seen, a common trend in the translation efforts of Facebook and Duolingo is the move from community and volunteer-based translations to commercial translation directed by the company. On the one hand, the reliance on unpaid work is problematic for a company with huge profits – something that Duolingo itself lists as the reason for ending the volunteer program [21]. This is especially true when those delivering this work might already be in unprivileged financial situation, as many indigenous language speakers are. On the other hand, however, this deprives the communities of the possibility to contribute to making their language more visible on the popular platforms. It is interesting to note that the translation platform of open-source based Mozilla products remains active, and, for example, the last changes to an Indigenous Language – Zapotec – have been done on 26th August 2024.

3 Digitally available Nahuatl language media

The importance of maintaining Nahuatl language learning apps is clearer if we consider that there are relatively few other resources in the language available online for language learners, many of whom are descendant from Nahuatl speakers and wish to reclaim the language of their ancestors.

[14] collected information about the different monolingual Nahuatl language media available for those searching on the internet. The results encompassed 12 monolingual novel-sized books, 5 scientific articles, 10 movies or series episodes, 1 videogame, 6 radio stations where Nahuatl is transmitted along with other languages, Wikipedia in 10 separate varieties, and 5 websites with a Nahuatl version. Considering that Nahuatl is the Mexican indigenous language with the biggest number of speakers, this is a low number.

However, there is hope that their number is increasing. For example, the 5 scientific articles were published in 1959, 2019, 2022, 2022, 2023; the 12 books in 2008, 2013, 2014, 2015, 2015, 2016, 2017, 2017, 2017, 2019 and 2021, (the twelfth is the Bible which has been translated into many varieties) [14]. One of the websites is also recent, as it was published in 2023 [22]. In 2024 the Mexican presidential election was simultaneously interpreted into Nahuatl, and remains, as of 30.08.2024, available on YouTube [23]. In addition, a Master´s degree in Nahuatl language and culture, taught completely in an indigenous language was launched in 2019 [24], first of its kind. We see therefore a clear tendency of growth, and it could be expected that more media will become available in Nahuatl soon.

It is also interesting to consider the case of the work to bring Nahuatl as a language available in Google Translate (https://translate.google.com/). In 2010, Google announced their plans to add Nahuatl and Maya to the tool [25], but this service was finally only introduced in June 2024 [26]. As of September 2024, the following ten indigenous American languages are among the 243 languages available on Google translate: Aymara, Guarani, Hawaiian, Kalaallisut, Mam, Nahuatl, Quechua, Q'eqchi', Yucatec Maya and Zapotec.

Considering mobile apps in particular, [14] identified 39 mobile phone apps related to Nahuatl. Most of them, 23, are Bible apps, although due to double versions, there are only 14 different variant versions of Bible available as a mobile app. The other 16 apps include 6 dictionaries (one with a Nahuatl user interface), 3 text collections, a (faulty) automatic translator, a multi-component app CEM, which combines dictionaries and morphological analyzer, the messaging app Telegram that offers user interface in Huasteca Nahuatl (albeit cannot be chosen in its standard menu, but is available for download for those who have the relevant link), and, finally, 4 Nahuatl language courses, discussed below.

4 A Partial History of Nahuatl Language Apps

As of 01.07.2023, four Nahuatl language courses were available for Android [14]: Aprende náhuatl [27], Beginner Nahuatl [28], Kamatlama [29] and NahuatlApp [30]. Aprende náhuatl (Spanish for "learn Nahuatl") is a vocabulary training app, with texts and videos, produced by the National Institute of Indigenous Peoples, a government agency and it was, as of 01.07.2023, downloaded more than 10 000 times [14]. As of 26.09.2024, it is available on

Android 14 for some, but not all devices. Beginner Nahuatl, with more than 1000 downloads as of the same date [14], was a vocabulary training app, without any game elements. Kamatlama is an app introducing basic numbers and fruit names and testing them through games and it was downloaded only more than 50 times as of 01.07.2023 [14]. NahuatlApp was an app introducing vocabulary items and testing them through a game and had, as of the same date, more than 10 000 downloads [14].

It is notable that the maintenance of the apps is far from ideal. Between the data collection of [14], 01.07.2023 and of [31], 30.05.2024, the videos of Aprende Nahuatl became unavailable and the two apps, Beginner Nahuatl and NahuatlApp, became unavailable for download on Google Play. During the same time, the user statistics did not change for the two continued apps, and crucially, Kamatlama hasn´t reached 100 downloads.

Two more apps mentioned by [14], although primarily dictionaries, also have elements supporting learning, such as quizzes: Totlahtol Nahuatl [32] and Diccionario Náhuatl [33]. As of 26.05.2024 Totlahtol Nahuatl, which offered Nahuatl user interface – as the only app other than Telegram - was no longer available for downloads, while Diccionario Nahuatl is still (01.09.2024) available. Additionally, Miyotl, a multilanguage app whose lesson components seem to never have been completed, remains available for download and contains a list of Nahuatl words and their Spanish translations [34].

In addition, as of 01.09.2024, 6 other apps mentioned by [14] are discontinued: the text collection Tlapohualiztli [35], the dictionary Diccionario Maya y Nahuatl [36] and the automatic translator Traductor Nahuatl [37]. This means that out of 16 non-Bible related apps mentioned by [14], 6 (Beginner Nahuatl, NauatlApp, Diccionario Maya y Nahuatl, Tlapohualiztli, Totlahtol Nahuatl, Traductor Nahuatl) have been discontinued only a year later (37.5%). In addition, [31] mentions three other apps that had been discontinued before: Tozcatl [38], Nahuatl Grammar [39] and Ma Tiwelikan Nawatl [40] – the latter is available as a website, but the App version is not available anymore. Furthermore, the app presented at the EUROCALL conference in 2016 [41] is also not discoverable on Google search, as of 18.06.2024.

However, the changes are not all negative. On 14th March 2024, user ItztliEhecatl posted on the social platform Reddit [42] that they have created a new Huasteca Nahuatl language learning course [43]. The author has been adding new items to the course, and as of 01.09.2024, there were 568 words and phrases to be learnt. The Huasteca Nahuatl course uses the Memrise Community Courses infrastructure, where users can create their own courses. However, in line with the trend discussed in section 2, Memrise is also closing community forums and removing community courses from their app and the future of the community courses remains uncertain beyond the end of 2024.

There is, however, another high-quality Nahuatl learning app for beginners that explains the grammatical concepts and tests them in a variety of exercises over 11 Units: the Nahuatl course hosted by the 7000 languages organization [44] and prepared in 2017 by Tlahtoltlapazolli, a Los Angeles based group [45]. The course requires registration, and only has a website version – although the mobile website version works well. However, the fact, that it is not listed in App stores decreases its findability.

Altogether, we see here that a great proportion of Nahuatl learning apps is discontinued. By the time they this happens, their content usually does not advance beyond the basic level, although one often has the impression that the authors had intended to add more lessons in the future. One could wonder whether a more stable app with more levels would have been possible if the authors had joined their efforts.

5 Long-term survival of Language apps: Discussion

The trajectory of some Nahuatl learning apps has helped us identify a trend of frequent discontinuation of those apps, lack of maintenance or upgrading to newer versions of operating systems or devices and a tendency by the commercial providers to dissolve community-led efforts of translation and localization and to limit the number of languages that the service is translated and localized into.

Admittedly, the frequent appearance and disappearance of new apps might be a sign of a vibrant, creative community. In fact, [7] sees it as a part of the process of app creation to accept that the results of one`s work on software localization might have a short life or never be used at all. If one accepts the possibility of failure (that is, the materials prepared ending up not being used) or only short-term success (that is, a short-lived app), the process of creating apps might be more spontaneous and less restricted, and the threshold to make such an app might be lower. In other words, if one does not strive to make “the perfect” app, creating an ad-hoc training exercises for one skill might become easier. However, even in this scenario, many contributors and authors might end up doing the same work unnecessarily, such as preparing grammatical description of the same grammatical forms destined for different apps.

In addition, one might also wonder if the low number of downloads discourages the authors to add additional levels and update their apps. However, given that Aprende Náhuatl, an App published by a government agency had more than 10 000 downloads, and up to 28 000 downloads [46], there is sufficient interest of learners in Nahuatl language apps, and perhaps a focus on better findability of the apps could result in their bigger success.

The question can therefore be posed how to better direct the efforts of authors and contributors, typically activists and volunteers, to not repeatedly make basic-level apps that might then be discontinued and to instead direct those efforts at more long-term apps which would also include levels for more advanced learners.

An open source platform that allows and tracks user edits, similar to Wikipedia (https://www.wikipedia.org/) or Wikitravel (https://wikitravel.org/) could allow users to collaborate in making language courses, and each individual author could make a small contribution, without the feeling that it was “in vain”. This would also prevent the fruits of work of language activists from “disappearing” in the chaos of the internet, and would increase their findability. Care must be taken to make such a platform independent of commercial companies that could unilaterally delete the courses from their servers. It is also recommended that information about such a platform be widely shared to avoid the situation where a good course ends up not being used due to being unknown to the learners.

Acknowledgments

I would like to thank the anonymous reviewer for their comments, which will serve as a guide in the subsequent research into the more specific reasons behind the discontinuation of the apps.

Designing the Flow State Experience Using Modern Digital Technologies

Eva Vidmar
Multimedia
Faculty of computer science
University of Ljubljana
Ljubljana, Slovenia
eva.vidmar2@gmail.com

Abstract

This article provides a brief overview of an extended Master's thesis and focuses on the use of modern digital technologies to design a multimedia environment aimed at inducing a state of flow in individuals. Flow is a psychological state characterized by deep immersion in an activity, leading to a loss of sense of time and external worries **[1]**. Exiting this state typically results in feelings of satisfaction and happiness. Achieving flow requires a balance between skills and challenges. Learning to attain this balance can help individuals improve overall, which is a key reason for this research. The main objective is to investigate whether flow can be achieved through the use of color light stimuli in a space that adapts in real-time to an individual's level of attention. This represents a preliminary step toward using technology to design spaces that stimulate individuals and facilitate the quicker and easier attainment of flow. An experiment was conducted to test whether such a space affects individuals' flow. Tetris was chosen as the central activity for the experiment. The findings indicated that color stimuli influenced the participants' physically measured attention, although no significant changes were observed in questionnaire responses or gameplay performance. Given that attention is a crucial factor in achieving flow, it can be partially asserted that participants experienced flow, though more reliable data would be necessary for further conclusions. These findings significantly contribute to the understanding of measuring and achieving flow through technology, representing an important advancement in this field.

Keywords

flow, optimal experience, user experience, digital interface, Tetris

1 Introduction

Historically, flow has been experienced by artists, athletes, and individuals with substantial practice. However, modern life, especially in technology-driven environments, necessitates new approaches to achieve this optimal state. This study investigates how real-time adjustments of ambient lighting, informed by physiological signals, can enhance flow experiences, offering a novel approach that builds on but goes beyond methods such as video games or Virtual Reality (VR). By integrating psychophysiology, user experience, and ambient intelligence, this research aims to leverage technology for meaningful improvements in well-being, productivity, and satisfaction.

2 Theoretical Background

Inducing a flow state through technology poses complex challenges that require in-depth exploration of the neurocognitive aspects of flow and their relation to contemporary technologies. This understanding informs the design of technological solutions aligned with flow theory.

2.1 A Neurocognitive Perspective on Flow

Flow, characterized by deep focus and immersion, was first described by Mihaly Csikszentmihalyi, often referred to as the "father of flow" [1]. This state occurs when individuals find an appropriate balance between their skills and the challenges they face, allowing them to perform optimally with a sense of effortless control [1]. While initial resistance and sustained motivation are necessary to achieve flow, this state can occur even in unfamiliar tasks, although long-term practice may increase its likelihood [2]. Flow is often illustrated in a two-dimensional graph where it exists at the intersection of appropriate challenge and skill levels [1].

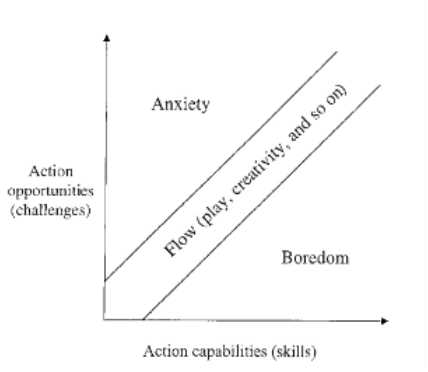

Figure 1: Graph representing occurrence of flow state [1]

Neuroscientific perspectives on flow suggest various underlying mechanisms. The transient hypofrontality hypothesis posits that during flow, activity in the prefrontal cortex decreases, reducing

self-criticism and enhancing performance [3]. Alternatively, synchronization theory proposes that flow arises from synchronized activation across different brain regions, optimizing cognitive efficiency [4]. Both theories indicate that flow entails minimal energy expenditure in the brain.

Csikszentmihalyi's model outlines optimal conditions for flow, including clear goals, immediate feedback, and a balance between challenge and skill [1]. The concept of the autotelic personality—marked by intrinsic motivation and enjoyment—may enhance flow experiences but is not strictly essential for achieving it.

2.2 Flow in Technology: State of the Art

Various approaches have emerged to induce flow through technology. Traditionally, video games employed fixed difficulty levels, which often interrupted the flow experience [5]. Dynamic Difficulty Adjustment (DDA) algorithms now allow real-time modification of challenges based on player performance, as seen in games like Left 4 Dead [6], [7, p. 4], Affective computing enhances this by using emotional indicators, such as facial expressions, to fine-tune difficulty levels [6]. Jenova Chen's game flOw exemplifies the integration of DDA with real-time adjustments to maintain flow [8]. Virtual Reality further immerses players, as evidenced by studies comparing VR to traditional 2D games and applications focused on meditation and relaxation [9], [10], [11]. Augmented Reality and multimedia art also contribute innovative avenues for inducing flow [12], [13].

Figure 2: Refik Anadol 2D projection Machine Hallucinations [12]

Our research identifies the use of ambient lighting as a promising yet under-explored method for inducing flow while engaging participants in a core activity, specifically Tetris. This game, created by Alex Pajitnov in 1985, has been extensively studied for its capacity to induce flow [14]. Players arrange falling blocks to form complete lines, receiving immediate visual feedback—key elements for maintaining flow. Research indicates that even brief sessions of Tetris can lead to flow experiences and reduced negative emotions [15].

2.3 Techniques for Flow State Measurement

Various methods exist to measure brain activity, with electroencephalography (EEG) being the most direct and commonly used. Functional Near-Infrared Spectroscopy (fNIRS) and Functional Magnetic Resonance Imaging (fMRI) provide insights into brain function, while Magnetoencephalography (MEG) offers high resolution of neuronal activity. However, these methods often involve expensive and less accessible equipment.

The MindWave Mobile 2, a consumer-grade EEG device, stands out for its ease of use, making it suitable for educational and entertainment contexts [16]. This device is ideal for our research due to its user-friendly nature, minimizing inconvenience for participants.

Figure 3: Mindwave Mobile 2 [16]

Flow state was traditionally measured through self-reporting instruments, such as the Experience Sampling Method (ESM) developed by Csikszentmihalyi [1]. Various questionnaires, including the Flow State Scale and Game Experience Questionnaire, have been developed to assess flow but rely on retrospective reporting. Alternatively, physiological measures may offer a more objective assessment of flow experiences.

3 Experiment: The Impact of Light on Flow State During Tetris Gameplay

This experiment investigated whether spaces incorporating adaptive technology could enhance user engagement. We compared standard Tetris gameplay to a version featuring color-changing lights that adjusted based on player attention, measured via the MindWave Mobile 2. The goal was to assess whether these technological enhancements positively impacted engagement and performance, specifically exploring if adaptive lighting improved attention, stabilized focus, and led to better gameplay results.

Drawing from Csikszentmihalyi's model, we recognized the importance of differentiating the environment in which flow activities occur. We aimed to create a highly engaging environment by designing a prototype of adaptive lighting for a dimly lit space.

For the experiment, we developed a color-changing light prototype controlled by the MindWave Mobile 2. The device measured brainwave activity during Tetris gameplay. We

utilized an Arduino Uno microcontroller to interface with the MindWave Mobile 2 and control a 2-meter AdaFruit NeoPixel LED strip. The light's color adjusted based on attention levels, with red indicating low attention, blue indicating high attention, and white representing optimal focus. This setup aimed to evaluate whether adaptive lighting could influence players' attention and flow during the game.

Figure 4: The setup of light prototype behind laptop

The experiment was designed to compare Tetris performance with and without adaptive lighting. Participants played Tetris under both conditions, and their attention levels, measured via the MindWave Mobile 2, were used to adjust the light's color dynamically. Data on engagement, attention, and gameplay performance were collected and analyzed to determine the effectiveness of the adaptive lighting in enhancing flow.

Figure 5: Scenario of playing Tetris with lights

3.1 Results

Data were collected from the MindWave Mobile 2, which recorded attention and meditation levels during Tetris gameplay with and without adaptive lighting. We filtered data to focus on attention values from 5 minutes of gameplay, excluding values below a threshold of 10 and retaining the 300 most representative data points. A Shapiro-Wilk test confirmed normal distribution for both conditions. A paired t-test revealed significantly higher attention levels during gameplay with lights (p-value = 0.00032). Notably, attention levels were more stabilized with adaptive lighting, as evidenced by a smaller variance in attention scores compared to gameplay without lights.

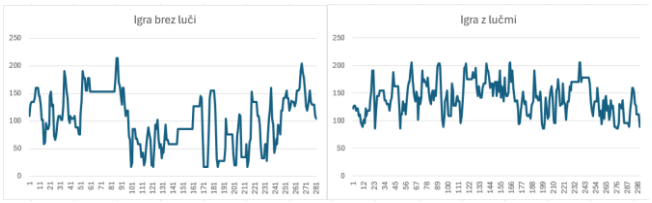

Figure 6: Attention levels of a player during gameplay without lights (left) and with lights (right)

For engagement, while the Shapiro-Wilk test confirmed normality, a paired t-test indicated no significant effect of lighting on engagement (p-value = 0.668). Tetris performance was assessed based on scores, with the group using lights achieving a higher average score (9377) compared to the no-light group (8979), though a Wilcoxon signed-rank test revealed no significant difference (p-value = 0.33).

Qualitative analysis of interviews with 40 participants identified seven key themes related to their experiences with the lighting: awareness of external stimuli, control and feedback, concentration, immersion, motivation, satisfaction, and pressure. Many participants reported feelings of pressure and stress, underscoring the challenges of achieving flow. Nonetheless, the lights were generally perceived as motivating, and some participants noted decreased awareness of their surroundings, aligning with theories regarding transient hypofrontality and reduced default mode network activity during flow [1].

Interestingly, some participants reported not noticing the lights at all, suggesting a potential subconscious influence of flow on their experience. This observation could have affected the questionnaire results. In terms of color perception, red was described as stressful and distracting, while white and blue were regarded as pleasant, showing no significant difference between them.

4 Conclusion

This study explored the potential influence of external factors, specifically technology-based lighting, on the state of flow. While we observed increased attention levels during gameplay with lights, supporting the theoretical premise that flow involves synchronized neural networks related to attention and reward, our hypothesis remains unconfirmed. Qualitative interviews highlighted themes consistent with flow characteristics, such as immersion and motivation; however, the absence of statistically significant effects on engagement and gameplay performance indicates that further research is warranted. Future studies should involve larger, more diverse samples and consider additional metrics to assess flow states more comprehensively.

Overall, our findings offer valuable insights into integrating technology with flow theory, highlighting the potential for developing products that enhance focus and user experience. This research lays the groundwork for future innovations aimed at creating more effective tools for achieving optimal states of concentration and fulfillment in everyday life.

Abstract

Nudges are a strategic approach that shapes decision-making environments and the presentation of options to steer individuals toward certain behaviors while maintaining their freedom of choice. The ethical concerns surrounding nudges center on their potential to undermine personal autonomy, particularly when individuals are unaware of the influence exerted on them (i.e., covert or non-transparent nudges). The proposed solution for preserving autonomy is to increase transparency, which includes disclosing the presence and purpose of nudges to the people that are being nudged. There are various types of nudges and different types and levels of transparency associated with them. The most problematic in terms of violating personal autonomy are the non-transparent ones, those that exploit automatic cognitive mechanisms (Type 1 nudges), those that use type transparency and those that disclose their nature only after the fact (ex post). New approaches such as nudge plus approach seek to protect personal autonomy by involving citizens in the creation of nudges and enhancing reflectiveness during the nudging process.

Keywords

Nudge, transparency, autonomy, ethics of nudging, nudge plus approach

1 Introduction

Over the past thirty years, psychology and behavioral economics have highlighted how various contextual factors systematically influence our decision-making and behavior. In public policy-making, these insights are crucial for effectively addressing societal challenges like global warming, obesity, and poor economic decision-making. The groundbreaking paper [1] and the book that followed that brought the importance of decision architecture to the attention of academics, policymakers, and the general public was Thaler and Sunstein's "Nudge: Improving Decisions About Health, Wealth, and Happiness" [2]. In their work, they propose various ways in which government and private organizations could encourage or "nudge" individuals toward actions beneficial to them, while promoting a method that preserves a strong commitment to freedom of choice. Behavioral insights show that the context of decision-making can lead us to act inconsistently with our otherwise well-informed intentions [2]. The traditional approach to public policy assumes people are perfectly rational economic subjects ("econs") who act optimally with accurate information and clear rules. While this is an admirable goal, Thaler and Sunstein warn that basing public policy on this ideal often leads to failure. The authors introduce the concept of a "nudge" and propose its use as a policy-making approach that can influence citizens' behavior while avoiding the pitfalls and issues of traditional regulatory approaches, such as prohibitions and punishments. The advantage of this approach is that policymakers can influence our choices and behavior in a cost-effective and efficient manner without restricting us with prohibitions or interfering with our choices [3]. Despite the high effectiveness and utility of nudges, ethical concerns arise regarding the preservation of autonomy, especially with nudges that operate covertly and influence us without our awareness. This article investigates various types of nudges and levels of transparency, with a focus on their implications for personal autonomy. It begins by elucidating key concepts—nudges, autonomy, and transparency—before analyzing how different types of nudges, alongside varying types and levels of transparency, affect the preservation or violation of personal autonomy. Additionally, the article proposes criteria for determining which types of nudges are compatible with the preservation of personal autonomy. Finally, it explores potential strategies to mitigate adverse impacts on autonomy, including enhancing transparency, fostering citizen participation, and integrating reflective practices into the design of nudges.

2 Definition of a nudge

Thaler and Sunstein define a nudge as any element of choice architecture that influences behavior in a predictable way without restricting options or significantly altering economic incentives [2]. A nudge subtly guides individuals toward better decisions while preserving freedom of choice by adjusting how choices are presented [4]. Unlike prohibitions or penalties, nudges steer behavior without limiting options. An example is placing healthy snacks at eye level in stores to encourage healthier choices [5]. Hausman and Welch [6] add that nudges influence choices without increasing costs or limiting options, highlighting the potential for manipulation, which raises ethical concerns discussed in later chapters.

3 How nudges work: leveraging heuristics and biases

To grasp how nudges impact behavior and decision-making, we must rely on insights from behavioral science, which reveal that nudges exploit inherent imperfections in human decision processes—leveraging cognitive heuristics and biases [4]. A key element of the nudge approach is that heuristics and biases, which often serve as mental shortcuts, are utilized to the advantage of the choice architect. While these mental shortcuts can sometimes lead to suboptimal decisions, a nudge aims to harness them to promote better decisions [3].

4 Nudge and ethical issues

Although the theory of nudging presents a promising approach to public policy, it has faced significant criticism from both public and academic spheres. Over the past decade, a robust ethical debate has developed, featuring nuanced arguments both supporting and opposing the practice [3, 4, 6, 7, 8]. The primary critique centers on the idea that nudging involves manipulating choices, with concerns about potential misuse of power [3]. Critics argue that nudges can undermine free choice by subtly restricting rather than fostering individual decision-making. The core of nudging involves exploiting heuristics and biases, which often lead people to act in ways that deviate from their well-considered preferences. Bovens [8] contends that such mechanisms can compromise control over actions, raising worries that nudges might affect decision-making by diminishing rational or deliberate considerations. Additionally, he argues, the behavior change induced by nudges occurs, if not against citizens' will, then at least without their active consent and awareness; for broader discussion about this topic see also [9, Ch. “Avtonomija v svetu spodbud” (Autonomy in the World of Nudging), pp.. 81-100; 10].

4.1 Ethical dilemma of autonomy in nudge use

Although nudges have been shown to effectively influence behavior, critics argue they can be manipulative and threaten personal autonomy. Autonomy, a complex concept, is broken down by Schmidt and Engelen into four dimensions: the freedom to choose without external pressure, acting according to one’s desires and values (psychological autonomy), making rational decisions based on available information, and being free from domination or manipulation [5, 8]. Critics claim that nudges can undermine autonomy by subtly influencing behavior without explicit consent, raising concerns about democracy, especially if governments use nudges without informing citizens. Nudges that operate without notice are especially problematic, as they can influence decisions without individuals' awareness. As Ivanković and Engelen [11] argue, non-transparent nudges, which exploit less rational psychological mechanisms, undermine autonomy by denying people control and the ability to challenge, a right that should be protected in liberal democracies. Sunstein, however, argues that nudges maintain freedom by allowing people to opt out of the suggested behavior, a concept they call "libertarian paternalism" [12]. They believe nudges, unlike traditional regulations, don’t limit freedom but instead encourage choices that align with individuals' best interests.

4.2 Transparency as a solution to autonomy violation

A proposed solution is increasing nudge transparency, as it allows individuals to understand how nudges work and make autonomous decisions based on their values [8]. A transparent nudge is one where its purpose and the methods used to influence behavior are reasonably clear to the affected individual. Thaler and Sunstein moreover argue that nudges used by governments should be public and transparent, with officials ready to disclose their methods and motives. Sunstein further emphasizes that nudges must be visible, reviewed, and monitored to prevent violations of autonomy or dignity [10]. Transparency involves informing decision-makers about the presence and purpose of nudges, allowing individuals to remain aware of behavioral interventions, thus preserving their autonomy and freedom of choice [7]. [1]

5 Types of transparency in nudging

To better understand the impact of nudging on an individual's autonomy, it is crucial to first examine the different types of nudges, as they are not a uniform phenomenon; rather, they can be classified into various types [2]. Understanding these types is based on dual-process theory, which describes the two decision-making mechanisms that nudges can influence.

5.1 Dual process theory

Dual process theory, explored by Stanovich [13] and Kahneman [14], is key in Thaler and Sunstein’s work on nudges. It suggests the brain operates in two modes: fast, intuitive System 1 and slow, deliberate System 2. System 1 handles instinctive actions, while System 2 engages in reflective decision-making. Despite its acceptance, dual processing is contested, with some scholars arguing the differences are a matter of degree. De Neys [15], notes no conclusive evidence favors either model, and resolving this debate may not significantly enhance our understanding of human thinking mechanisms. In this article, we adopt the dual process theory model to categorize different types of nudges. This approach allows us to better understand and design interventions that leverage both intuitive and reflective processes.

5.2 Type 1 and Type 2 nudges

According to Hansen and Jespersen [3], nudges can be categorized into two types based on dual process theory. Type 1 nudges target automatic, non-reflective thinking (System 1) and operate unconsciously, such as subliminal advertising or visual stimuli that influence behavior without conscious awareness. These nudges can be ethically problematic, as they often lack transparency and may lead to decisions misaligned with personal values. In contrast, Type 2 nudges engage reflective, deliberate thinking (System 2), promoting informed and thoughtful decision-making. These nudges are transparent and pose fewer ethical concerns regarding personal autonomy.

[1] Empirical evidence is inconsistent regarding the impact of transparency on the effectiveness of nudges. Transparency may: reduce their effectiveness (by prompting reflection), make nudges counterproductive (if people resist disliked nudges), enhance their effectiveness (if people understand and support the underlying goals), or have no significant impact at all [10].

5.3 Different types of transparency of nudges

The transparency of nudges plays a crucial role in safeguarding autonomy and freedom of choice, yet this concept itself is multifaceted. On one side of the spectrum, some nudges are explicitly transparent, functioning effectively because the individual is fully aware of the influence being exerted. Conversely, some nudges operate more subtly, relying on a lack of transparency to achieve their intended effect. To thoroughly assess which forms of transparency in nudges may raise ethical concerns, it is important to analyze the various ways in which transparency can manifest within nudges.

5.4 Type and token transparency

Bovens [8] introduces a crucial distinction between type and token transparency in nudges. Type transparency refers to when governments inform citizens about the general techniques they employ to intervene in decision-making contexts for the purpose of enhancing well-being. In this scenario, the government is open about the categories of measures it plans to implement. For example, when a government announces its intention to use specific psychological mechanisms to address social challenges, it demonstrates type transparency by clearly stating the kinds of interventions it will use to influence individuals' behavior and decision-making [16]. However, Bovens stresses that this is not enough. In his view, subliminal advertising does not become more acceptable simply because it is openly acknowledged [8]. On the other hand, token transparency requires that each individual instance of a nudge is clearly recognizable, including how it was implemented. This method, referred to as "here and now approach," aims to ensure that nudges are transparent to those encountering them at the moment of their decision-making [12]. However, even if this were feasible, it seems absurd to demand that every nudge be accompanied by a notice of its use. Since choice architecture is often unavoidable, token transparency may be too demanding, according to Bovens [8].

5.5 Levels of transparency

Transparent nudges differ also based on when they are noticed by the nudged individuals. With nudges that are transparent in advance (*ex ante*), the user can see the nudge beforehand and can avoid it if they choose. An example is traffic light labels (green, yellow, red) for healthy, less healthy, and unhealthy food products [17]. In contrast, a nudge is transparent afterward (*ex post*) if the target person only notices its influence after it has already affected them. Examples include fake cracks painted on the road to slow down drivers or the use of default options in certain contracts. Only after experiencing the effects do people realize they were influenced by a nudge [12]. Unlike the first category, the potential impact of such nudges on people's autonomy is more significant here. Ex post transparency may be insufficient to ensure autonomous action if it depends on individuals' ability to avoid the nudge. If transparency is meant to ensure that nudges do not deter people from achieving their goals and values, then, according to Ivanković & Engelen, ex post transparent nudges should either be excluded or efforts should be made to turn ex post transparency into ex ante transparency [11]. Occasionally, ex post transparent nudges become ex ante transparent through repeated exposure. For example, a fake speed bump may not have the same effect twice if the person learns when and where to expect it. With repeated exposure to such nudges, individuals may become more aware of their influence and may eventually avoid them altogether [12].

6 Types of nudges and transparency: impact on personal autonomy

The debate over nudges centers on how different types of nudges as well as types and levels of transparency impact personal autonomy. As stated in the article, nudges are divided into two types: Type 1, which influence automatic, non-reflective behavior, and Type 2, which target reflective decision-making. Transparent Type 2 nudges, which engage reflective capacities, do not typically raise ethical concerns, as they allow for conscious and deliberate decision-making. In contrast, non-transparent Type 1 nudges, which act on automatic processes, can threaten autonomy by influencing behavior without the individual's awareness. This may lead to decisions misaligned with personal values or goals. Transparency is categorized into type transparency (general awareness of the nudge type) and token transparency (awareness of mechanisms of specific nudges). The former is particularly problematic, as it lacks disclosure of specific examples and mechanisms, leaving us potentially unaware of the influences on our behavior. Nudges can also be categorized by the level of transparency into two main groups. The first group includes nudges that are transparent in advance by design (ex ante). These nudges are openly presented, allowing users to consciously decide whether to respond to them. Such nudges generally do not threaten autonomy, as they encourage conscious and deliberate decision-making. The second group includes nudges that are only transparent afterward (ex post). These nudges can be problematic, as users may respond to them before realizing they have been nudged. Although information about the nudge is revealed later, it may already have influenced behavior in a way that threatens freedom of choice and autonomy [18]. In conclusion, the most problematic nudges, in terms of violating personal autonomy, are Type 1 nudges that exploit automatic cognitive mechanisms, lack transparency—where type transparency is more concerning than token transparency—or are only transparent afterward. Understanding and using nudges requires careful consideration of their transparency and impact on freedom of choice. While transparent nudges can serve as tools for encouraging thoughtful and autonomous decisions, non-transparent nudges, as well as Type 1 nudges, especially those with only type or post hoc transparency, must undergo thorough ethical scrutiny to prevent potential violations of personal autonomy.

Table 1: Classification of nudges based on their impact on personal autonomy

Nudges that violate autonomy	Nudges that do not violate autonomy
Type 1 nudges	Type 2 nudges
Type transparency	Token transparency
Ex post transparent nudges	*Ex ante* transparent nudges

This table helps determine whether a nudge preserves autonomy, but it's unclear how many criteria must be met to deem a nudge ethical or unethical. Further research is needed for clearer guidance.

6.1 Collaborative policy design: The nudge plus approach

The nudge plus approach extends beyond transparency by encouraging participatory engagement and reflection, viewing individuals as rational, reflective beings rather than passive agents. Unlike traditional nudging, which can influence behavior unconsciously, nudge plus focuses on democratic control and active collaboration between citizens and policymakers. Through methods like citizens' assemblies, participants are directly involved in policy design, contributing ideas that shape their environments. In the UK, medical sciences now require patient and public involvement in all research that includes patient populations. Similarly, adolescents are consulted in developing anti-bullying interventions [19]. These approaches foster mutual feedback and collaboration between policymakers and citizens, leading to more inclusive and transparent policies that respect community values. Nudge plus approach also refers to an intervention that has a reflective strategy embedded into the design of a nudge. Banerjee and John [20] state that this preserves personal autonomy while promoting pro-social interventions through active involvement by enhancing token transparency and decision-making autonomy. The nudge plus approach offers significant potential for enhancing public policy with maintaining individual autonomy. By embedding reflection, transparency and active citizen engagement, it encourages people to participate in decision-making rather than passively accepting nudge type interventions. This participatory approach builds trust, as individuals are more likely to embrace policies that respect their autonomy and align with their values.

7 Conclusion

This article reviewed nudges as tools for influencing decision-making and behavior, with a focus on their transparency and its influence on potential infringement of personal autonomy. We found that nudges vary in type and transparency, which significantly affects their ethical acceptability. Type 1 nudges, which target automatic decision-making mechanisms, can diminish personal autonomy by influencing behavior without conscious awareness. In contrast, Type 2 nudges, which encourage reflective decision-making, are less problematic as they support autonomous decision-making. Nudges that lack token transparency or are only transparent after the fact are more likely to infringe on autonomy. Conversely, when nudges are transparent in advance and individuals are informed about them, autonomy is better preserved. Additionally, the context in which nudges are implemented plays a critical role in their ethical assessment, as the goals and values of the intervention must align with those of the individuals affected. In conclusion, the ethical use of nudges in public policy requires focusing on preserving autonomy by choosing Type 2 nudges and ensuring high levels of transparency, especially regarding specific examples and advance notice. This approach allows nudges to support conscious decision-making rather than serving as tools for covert manipulation. The Nudge Plus approach, which adds an element of reflection, can enhance both the effectiveness and ethicality of interventions, empowering individuals to make more informed decisions.

Povzetek

Prispevek se ukvarja z vprašanjem, ali veliki jezikovni modeli v okviru generativne umetne inteligence že danes odpirajo vrata v fazo splošne umetne inteligence in morda – kot naslednji korak – v fazo umetne superinteligence. S tem bi bili dani predpogoji za prevlado strojev nad ljudmi. Pozornost je namenjena zlasti uporabi velikih jezikovnih modelov v procesu znanstvenega raziskovanja. Raziskovalna dejavnost predstavlja eno najbolj ustvarjalnih človekovih intelektualnih dejavnosti. Logično vprašanje je, ali je ravno znanstvena dejavnost, predvsem zaradi svoje kreativne narave, najbližja prečkanju te meje, ki predstavlja pomembno eksistenčno tveganje za celotno človeštvo. Osrednji del razprave je namenjen vprašanju, v katerih fazah današnjega znanstvenega raziskovanja je vloga velikih jezikovnih modelov že postala nepogrešljiva.

Ključne besede

generativna umetna inteligenca, veliki jezikovni modeli, znanstvena kreativnost, eksistenčno tveganje, okrepljeno učenje

Abstract

The article addresses the question of whether large language models within the framework of generative artificial intelligence are already opening the door to the phase of artificial general intelligence and, perhaps, as the next step, to the phase of artificial superintelligence. This would set the conditions for machines to dominate humans. Particular attention is given to the use of large language models in the process of scientific research. Research activity represents one of the most creative human intellectual endeavors. The logical question arises whether scientific activity, especially due to its creative nature, is the closest to crossing this boundary, which poses a significant existential risk to all of humanity. The central part of the discussion focuses on the question of which phases of today's scientific research the role of large language models has already become indispensable.

Keywords

generative artificial intelligence, large language model, scientific creativity, existential risk, reinforcement learning

1 Uvod

V okviru pričujoče obravnave izhajam iz predpostavke, da se je skozi celoten zgodovinski razvoj umetne inteligence implicitno zastavljalo vprašanje, ali lahko ta doseže oziroma celo preseže človeško inteligenco. Že od začetkov razvoja umetne inteligence so bila tovrstna razmišljanja spodbujena z različnimi testi, ki naj bi med drugim nakazovali, ali se strojna "inteligenca" približuje človeški inteligenci. Pomembni premik v teh razmišljanjih se je zgodil, ko je tehnologija umetne inteligence prešla od klasičnih načel strojnega učenja k načelom delovanja globokih nevronskih mrež. V moji razpravi me v prvi vrsti zanima, ali najnovejši razvoj generativne umetne inteligence že kaže znake prehoda v fazo umetne splošne inteligence in morda – kot naslednji korak – umetne super inteligence. Posebej me zanima, ali najbolj kreativna področja človekovega intelektualnga delovanja, kot to predstavlja znanstveno raziskovanje, že odpirajo vrata nastopu umetne splošne inteligence. To namreč pomeni, da se počasi trasira pot nadvladi strojev nad človekom, kar je sicer predmet precej distopičnih razmislekov filozofov in družboslovcev, tako pri nas kot drugje v svetu. Moja obravnava ostaja na ravni nekoliko bolj splošne družboslovne refleksije o tej kompleksni tematiki in se ne ukvarja z ožjimi tehničnimi vidiki delovanja umetne inteligence, zato se bom v primeru sklicevanj na algoritme delovanja umetne inteligence oprl na nekoliko bolj poljudne definicije, kot so na primer tiste, ki jih je predstavil Partha Ray [1]. Po Rayu generativna umetna inteligenca (GUI) spada v skupino modelov umetne inteligence, ki lahko ustvarjajo nove podatke (informacije) na podlagi vzorcev in struktur, naučenih iz obstoječih podatkov (informacij). Ti modeli lahko

generirajo vsebine na najrazličnejših področjih, naj si bo besedil, slik ali glasbe. Pri analizi, razumevanju in ustvarjanju teh vsebin, ki vedno bolj spominjajo na človeške stvaritve, se opirajo na tehnike globokega učenja in nevronske mreže. Veliki jezikovni modeli (VJM), ki se razvijajo pod okriljem GUI, pa so zasnovani za generiranje naravnega jezika, kot so stavki, odstavki ali celotni dokumenti. Njihova ključna lastnost je zmožnost predhodnega učenja na velikih količinah besedilnih podatkov ter nato prilagajanje za specifične naloge uporabnikov. V prispevku v štirih krajših poglavjih razpravljam (1) o umetni splošni oziroma super inteligenci kot dejavniku tveganja o človeku, (2) o dilemah, ki so povezane z nadvlado stroja nad človekom, (3) o danes vedno bolj nepogrešljivi vlogi VJM v posameznih fazah znanstvenega raziskovanja, (4) o specifičnih problemih uporabe VJM na področju družboslovnega raziskovanja. Na koncu prispevka je podanih še nekaj zaključnih misli.

2 Umetna super inteligenca kot dejavnik eksistenčnega tveganja za človeka

Potem ko je Nick Bostrom pred desetimi leti postavil in utemeljil tezo, da obstaja verjetnost, da bo nadaljnji razvoj umetne inteligence pripeljal do nastopa umetne superinteligence, ki naj bi bila neprimerno bolj kognitivno zmožna kot človek, kar bi lahko predstavljalo eksistenčno tveganje za celotni človeško vrsto, ta tema, zlasti po nastopu GPT 4 in drugih vrst VJM (Bard, Claude, Llama, Gemini, itd.) vzbuja vedno večjo pozornost med strokovnjaki, tako med naravoslovci in tehniki kot tudi med družboslovci in humanisti [2]. V svojem prispevku se bom izognil (spekulativnim) ocenam, ki se vrtijo okrog problema časovnih mejnikov, ko (če) naj bi pametni stroji nadvladali ljudi. Ena skupina ekspertov namreč trdi, da se to ne bo zgodilo niti v sto letih [3], druga skupina ekspertov spet trdi, da gre zgolj za vprašanje dveh ali treh desetletij [4]. Bolj kot to, me zanima, ali uporaba GUI v takšni kreativni človekovi dejavnosti kot je znanost resnično na široko odpira vrata nastopu umetne splošne oziroma umetne super inteligence, ki naj bi se sicer zgodila v bližnji prihodnosti. To vprašanje je treba povezati s konkretno prisotnimi strahovi pred katastrofičnimi in celo eksistenčnimi tipi tveganj GUI, ki bi lahko imeli negativne družbene posledice. Če katastrofično tveganje ocenjujemo po kriteriju maksimalne razširjenosti (število ljudi, ki bi bili prizadeti), intenziteti (trpljenju, ki ga povzroča) in trajanja škodljivih družbenih posledic nekontroliranega razvoja posamezne tehnologije, potem pri eksistenčnem tveganju, ki naj bi bil povzean z umetno inteligenco, odločilno vlogo igra samo en kriterij: nevarnost iztrebljanja človeške vrste zaradi prevlade stroja nad človekom.

Neredko se srečujemo z ocenami, da pomembni predpogoj za varni prihodnji razvoj GUI, v okviru katerega se lahko izognemo eksistenčnim tipom tveganj, predstavlja »algoritem okrepljenega učenja« (v ang.: »reinforcement learning algorithms«) [5, 6]). Pri »okrepljenem učenju« gre za to, da se v procesu sprejemanja odločitev nagradi to, kar vodi v dobrobit ljudi. Vendar v konkretnih situacijah težavo predstavlja praktično usklajevanje funkcij umetne inteligence z sprejetimi družbenimi vrednotami. Čeprav se ta problem na prvi pogled zdi trivialen, temu ni tako. Družbene vrednote so raznolike, amorfne in jih je težko zapopasti v kvantitativnih kategorijah. Problem, kako »okrepljeno učenje« uskladiti z sprejemljivimi družbenimi vrednotami, zato ni nekaj, kar se da na zelo enostaven in samoumevni način razrešiti. Njegova razrešitev je odvisna od več dejavnikov. Eden izmed teh je možnost, da se modeli GUI razvijajo kot odprtokodni modeli, kar je seveda v nasprotju z sedanjo strategijo multinacionalk, da preko lastniškega nadzora novih naprednih tehnologij javnosti prikrivajo ključne informacije.

Negativna posledica lastniškega odnosa do VJM je, da znanje o notranjih mehanizmih delovanja VJM, ki predstavljajo vrh razvoja umetne inteligence danes, še vedno predstavlja izziv za večino uporabnikov, (deloma) pa tudi za strokovnjake s področja računalništva. Težko je namreč analizirati in priti na tej osnovi do razumevanja VJM, ki delujejo v okviru kompleksnih notranjih struktur z milijoni parametrov. Četudi lahko v vlogi uporabnikov ali celo računalniških razvijalcev vidimo končni rezultat delovanja VJM, pa je pojasnitev oziroma interpretacija njihovih notranjih struktur izjemno zahtevna. Skratka, veliki jezikovni modeli še vedno nastopajo kot »črne skrinjice« (»black boxes«). Thomas Arnold je za opis te nevzdržne situacije uporabil naslednjo posrečeno analogijo: »To je tako kot da bi se prizadevali za razlago delovanja kompleksne kemijske reakcije, ne da bi poznali natančno strukturo in interakcijo molekul.« [7] V strokovni literaturi se sicer omenja tudi nekaj izjem. Za modele kot so BLOOM, Cerebras-GPT ali Llama, naj bi podjetja, ki se ukvarjajo z umetno inteligenco, dopuščala večji javni vpogled [8]. Spet za druge so informacije za javnost odprli, potem pa ponovno zaprli. Četudi vrhunski znanstveniki, ki se ukvarjajo z UI in prihajajo iz akademske sfere znanosti, v vedno večjem številu opozarjajo, da je prosti dostop do vseh informacij na tem področju eden ključnih dejavnikov, ki lahko zagotovi verodostojno in zanesljivo raziskovanje, saj le tako lahko dostopamo do informacij o celotni »arhitekturi« VJM (t.j. od uporabljenih podatkovnih baz do algoritmov), v zvezi s tem še vedno ni bilo storjenih veliko sprememb.

3 Ali lahko ustvarjalno dimenzijo znanstvenega dela dokončno prevzame umetna inteligenca?

Na prihodnje izzive, ki so povezani z nastopom umetne splošne oziroma umetne super inteligence, je treba gledati tudi v luči današnjih dogajanj. Že danes si lahko zastavljamo vprašanje, ali bo ustvarjalno znanstveno delo dokončno prevzela GUI: ali je res upravičeno trditi, da kar je nekoč kalkulator pomenil za številke, in kar internet za globalni značaj komunikacijo, to danes pomeni za znanstveno kreativnost razvoj GUI? Znanstveno kreativnost lahko subsumiramo pod bolj splošni pojem inteligence. Ta naj bi načeloma izkazovala celo paleto zmožnosti, od kreativnih do racionalnih oblik (znanstvenega, umetniškega, itd.) mišljenja, od načrtovanja do učenja na temelju izkušenj, itd. Četudi danes spekuliramo, da bo splošna umetna inteligenca dosegla ali presegla inteligenčne zmožnosti ljudi, pa bomo v strokovni literaturi težko naleteli na neke soglasne kriterije, ki naj bi povedali, kaj predstavlja »inteligenca« pri strojih in kaj predstavlja inteligenca pri ljudeh. Formalne definicije, ki vztrajajo ne nekem skupnem imenovalcu, nam niso vedno v pomoč. Nobena izmed teh formalnih definicij ne ponuja nekega dokončnega kriterija, ki bi nam omogočal primerjavo »inteligentnosti« različnih entitet. Če se za hip ustavimo ob najnovejšem delu Yuval Noaha Harareja, ki nosi naslov »Nexus. A Brief History of Information Networks from the Stone Stage to AI« [9], bomo pri njemu hitro prepoznali besednjak, ki naj bi

nedvoumno nakazoval, da GUI poseduje moment intencionalnosti, t.j. sposobnost GUI slediti delovanju, ki izhaja iz njih samih. (Avtor knjige govori o tem, da se pametni stroji, ki jih vodi GUI, sami odločajo, izbirajo, delujejo, itd.). Ob prebiranju najnovejšega Hararejevega dela se lahko vprašamo, zakaj vsiljuje intencionalnost kot ključni kriterij za izenačevanje »inteligentnosti« človeka in stroja. Lahko bi uporabil širšo definicijo inteligence in bi le to pripisal že entitetam, ki so pasivne, torej ne vključujejo momenta intencionalnosti, vendar vseeno reagirajo na okolje in lahko opravljajo kompleksne naloge. To je na primer storil Sebastien Bubeck, ki je skupaj z soavtorji preučeval, ali so v jezikovnem modelu GTP-4 že dani zametki umetne splošne inteligence. Postavil je namreč tezo, da si neko inteligentno entiteto lahko predstavljamo tudi kot »orakelj«, ki nima notranjih vzgibov ali želja za delovanje, vendar lahko natančno in koristno zagotavlja informacije o kateri koli temi ali domeni vedenja [10]. Definicijo inteligence, ki izhaja zgolj iz kriterija intencionalnosti, imamo lahko za restriktivno še iz enega razloga. Če namreč pri tej definiciji izhajamo iz notranjih motivov za doseganja ciljev našega delovanja v kar se da širokem okolju, kjer se soočamo z nikoli zaključenim spektrom situacij, potem v primeru rabe takšne definicije implicitno predpostavljamo, da je pojem inteligence neizogibno vezan na univerzalnost in optimalnost. To pomeni, da spet operiramo z apriorno definiranim in ne aposteriorno preverjenim konceptom inteligence. Dejansko oziroma realno inteligenco človeka namreč nikakor ne moremo opredeliti kot absolutno univerzalno in optimalno.

S podobnimi dilemami se soočamo, če naš pogled usmerimo na kreativnost kot eno izmed dimenzij človekove inteligence. Tudi v tem primeru odgovor na vprašanje, ali umetna inteligenca enostavno privzema kreativne moči znanosti, ni enoznačen. Ne gre samo za to, da se že pri vprašanju kreativnosti človeka srečujemo z ogromnim številom definicij (znanstveniki uporabljajo danes več kot 50 definicij [11]), zadeve postanejo še bolj kompleksne, ko iščemo skupni imenovalec med definicijo človeške kreativnosti in kreativnostjo, ki jo pripisujemo umetni inteligenci. Na eni strani imamo avtorje, kot so Marc Ruco [12] ali Stephen Rice [13], ki pravijo, da kolikor k standardnim definicijam človekove ustvarjalnosti – ta vključuje dimenzijo originalnosti in učinkovitosti - dodamo tudi dimenziji avtentičnosti, potem GUI ne more tekmovati z ljudmi.

Na drugi strani imamo avtorje, kot na primer Hubert Kent, za katere je GPT- 4 že dosegel izredno visoko stopnjo znanstvene kreativnosti, vsaj kar zadeva t.i. odprti tip mišljenja, saj naj bi empirične analize pokazale, da GPT-4 že zmore doseči rezultate, ki so enaki rezultatom, ki jih doseže zgolj 1% najbolj inteligentnih ljudi [14]. Rezultati dodatnih študij naj bi ravno tako dokazovali, da model GPT-4 izkazuje veliko stopnjo fleksibilnosti zunaj ustaljenih okvirov mišljenja in naj bi imel na področju odprtega tipa mišljenja celo višji kreativni potencial od ljudi. Pričakovati torej je, pravijo avtorji, ki so opravili te in podobne študije, da bo model GPT-4, kolikor bo dosežen napredek glede povečanih zmožnosti učenja na velikih bazah podatkov in bolj napredni arhitekturi nevronskih mrež, kmalo storil pomembni korak v smeri umetne splošne inteligence.[15]. V tem primeru Turingovi testi že zvenijo zastarelo. V okviru rabe Turingovega testa gre namreč za to, da se kot kriterij izenačitve dveh inteligenc vzame situacijo, ko nek uporabnik, ki komuncira z klepetalnikom UI, ne zna več ločiti, ali je na drugi strani človek ali stroj [8].

4 Zakaj umetna inteligenca postaja vedno bolj nepogrešljiv pomočnik v vseh fazah znanstvenega raziskovanja?

V okviru moje razprave me ob bolj načelnem epistemološkem vprašanju, t.j. ali nova tehnologija umetne inteligence postopoma zavzema prostor znanstvene kreativnosti, zanima tudi bolj konkretno vprašanje: ali ta nova napredna tehnologija dobiva status nepogrešljivosti v vseh drugih fazah znanstvenega raziskovanja?

Sodobno znanstveno raziskovanje je multidimenzionalni proces, ki vključuje različne faze, ki od začetka raziskovanja do končne objave znanstvenih rezultatov segajo od najbolj rutinskih pa do najbolj ustvarjalnih aktivnosti. VJM v tem primeru prevzema vlogo koristnega in vedno bolj nepogrešljivega »asistenta« v vseh fazah znanstvenega raziskovanja. Bo ta »asistent« v bolj ali manj oddaljeni prihodnosti postal »profesor«, ki bo dokončno nadomestil človeka – znanstvenika?

1. Najprej je treba izpostaviti, da GUI zaradi svoje učinkovitosti vedno bolj nadomešča znanstvenike v postopkih pridobivanja podatkov. Podobno je z učinkovitostjo GUI v vsebinskem pregledovanju, povzemanju in sumiranju množice informacijskih virov, ki so kot »state of the art« relevantne v vsakem začetnem procesu znanstvenega raziskovanja. GUI je sposoben obdelave in analize velike količine podatkov. Vloga GUI postaja neprecenljiva pri pregledu in sintezi vsebin iz znanstvene literature, povzemanju podatkov in sinteze kompleksnih podatkovnih baz, samodejnem prepoznavanju vzorcev in trendov, ki jih je mogoče izpeljati iz podatkov, modeliranju in napovedovanju na temelju zbranih podatkov, itd.
2. Vedno bolj se povečuje vloga GUI pri ustvarjanju novih idej. Glede na današnjo eksponentno rast znanstvenih informacij je prenos te raziskovalne funkcije iz človeka na GUI hkrati povezana z zmožnostjo GUI, da učinkovito in predvsem avtonomno ustvarja nova raziskovalna vprašanja in hipoteze. Eden največjih izzivov najbolj naprednih področij znanosti je skorajda neskončno število hipotez, ki se nanašajo na raziskovalne probleme, zaradi česar se včasih zdi natančno sistematično raziskovanje, ki bi omogočalo sprejetje hevristično najbolj obetavne hipoteze, brez sodelovanja UI skorajda nemogoče. Primer: v biokemiji naj bi obstajalo približno 10^{60} molekul, to pa je praktično enako številu zdravil, ki jih je treba na temelju ogromnega števila molekul šele odkriti [16]. Pri tem imajo ravno najnovejši modeli GUI potreben potencial, da revolucionarno posežejo v to fazo znanstvenega raziskovanja, ko gre za biokemijo. Podobne primere bi lahko navedli za področje genomike, astronomije, kvantne fizike, itd. Ne moremo mimo omembe še ene funkcije GUI. Ta funkcija GUI je vezana na njeno zmožnost usmerjanja k bolj interdisciplinarno zasnovanim revolucionarnim znanstvenim odkritjem, saj so njeni potenciali pri obdelavi in sintezi informacij iz različnih disciplin skorajda neomejeni.

3. Vloga GUI se povečuje tudi v procesih evalvacije končnih rezultatov znanstvenega raziskovanja. Če izhajam iz bolj splošnih epistemoloških predpostavk in se na tem mestu izognemo razpravi o prednostih in tudi tveganjih uporabe GUI v konkretnih recenzentskih postopkih, potem naj na kratko omenimo zgolj eno izredno pomembno vlogo te nove napredne tehnologije, t.j. preverjanje rezultatov eksperimentalnih in drugih empiričnih raziskav. V preteklosti je v glavnem veljalo, da ni problematična ponovljivost dobljenih znanstvenih rezultatov, bodisi na temelju javno dostopnih znanstvenih objav ali ustreznih eksperimentalnih protokov. Sodobna znanost se nahaja v vedno večji krizi, kar zadeva zmožnost replikacije, saj je tako z vidika časa kot tudi stroškov v številnih, če ne kar vseh vseh znanstvenih disciplinah težko izvesti potrebne eksperimentalne in druge znanstvene ponovitve. O tveganjih za povečanje goljufij in prevar v moderni znanosti, ki izhajajo iz teh kompleksnih situacij raziskovalnega dela, sem več pisal na drugih mestih [17]. GUI lahko odigra zelo relevatno funkcijo v današnjem času enormne produkcije znanstvenih rezultatov, ko je vedno težje izvajati ponovitve eksperimentov z namenom izvajanja kontrole znanstvenih rezultatov. Njen predikativni pristop namreč lahko zagotovi učinkovito, hitro, sistematično in natančno napoved ponovljivosti posameznih znanstvenih odkritij ali pa celo vseh spoznanj na posameznem področju znanosti.

4. Pozitivna vloga GUI se danes povečuje tudi v okviru širših družbenih in kognitivnih predpostavk, ki so relevantne za delovanje moderne znanosti. V zvezi s to širšo funkcijo bi izpostavil vlogo GUI pri spodbujanju komunikacij znotraj znanstvene skupnosti, pa tudi komunikacije znanstvenikov navzven. To zadnje naj bi se dogajalo predvsem s pomočjo modela ChatGPT, ki generira takšne tipe pojasnitev, ki vodijo k premagovanju komunikacijskih prepadov med eksperti in laiki. Vendar je to funkcijo, kot smo že opozorili v enem izmed predhodnih poglavij, mogoče izvajati le, če bo prišlo do uveljavitve nove paradigme odprtokodne znanosti. V zadnjem času strokovnjaki, ki delujejo na področju GUI, vedno bolj poudarjajo, da je treba razviti modele, ki bodo čim bolj korespondirali z fizično realnostjo. Menijo, da je treba največ naporov usmeriti v nadaljnji razvoj multimodalnih sistemov GUI. Demis Hassabis, izvršni direktor firme DeepMind, je v intervjuju za angleški dnevnik Guardian konec prejšnjega leta dejal, da je bil storjen na tem področju največji korak z modelom Gemini, ki ga razvija njegovo podjetje [18].

5 Ali nova tehnologija generativne umetne inteligence v okviru družboslovnega raziskovanja nujno in vedno zagotavlja znanstveno objektivnost?

Kot družboslovca me seveda zanima tudi vprašanje vedno večje rabe VJM na področju mojega področja znanstvenega raziskovanja. Kar takoj je treba reči, da na področju družbenih ved VJM izkazujejo velik (hevristični) potencial v razvijanju novih pristopov k anketnim raziskavam in ponovljivosti eksperimentov na področju vedenjske ekonomije [19], diskurzivnih analizah tekstov, ki jih je mogoče izvajati na avtomatizirani način [20] in končno tudi na področju razvijanja modelov, ki simulirajo stvarno obnašanje ljudi. V tem zadnjem primeru gre predvsem za t.i. »agent-based« modele, ki preučujejo, kako delovanje oziroma vedenje na mikro ravni (npr.: odločitve individualnih agentov) vodi do posledic na makro (družbeni) ravni (npr.: oblikovanje družbenih vzorcev delovanja oziroma obnašanja). V okviru teh modelov se seveda lahko preučuje tudi obratni vpliv: kako makro-nivo vpliva na obnašanje na mikro ravni [8]. V okviru sociologije se s temi »agent-based« modeli preučuje socialna omrežja, oblikovanje sosedskih skupnosti, itd.

Se pa v zvezi z družboslovnim raziskovanjem pojavlja določen paradoks, na katerega želim opozoriti v tem sklepnem delu moje razprave. Ta paradoks predstavlja dejstvo, da postopki »okrepljenega učenja« (ang. »reinforcement learning«), ki naj bi odpravili »halucinacije« in raznovrstne pristranosti, predstavljajo oviro za doseganje objektivno veljavnih znanstvenih rezultatov. Če pride skozi delovanje t.i. »reinforcement self-learning by human feed-back« (RLHF) do idealiziranja sveta, t..j. sveta, kakršen naj bi bil, ne pa sveta, kakršen dejansko je, takšna prizadevanja za zmanjšanja pristranskosti algoritmov, katerih cilj je promovirati liberalne vrednote, lahko ogrozijo veljavnost raziskav v družboslovju, ki jih podpira umetna inteligenca. »Požarni zid«, ki se ga želi danes pospešeno graditi preko RLHF, odpravlja tveganja GUI, kar zadeva njeno široko uporabo (in preprečuje tveganja, ki so se, kot pravi Yuval Harare, že zažrla v civilizacijski kod sodobnih družb), po drugi strani pa predstavlja epistemološko tveganje za objektivni značaj današnjih družboslovnih raziskav. Tudi to predstavlja dilemo današnjega in prihodnjega razvoja umetne inteligence, ki zahteva naš celovit interdisciplinarni razmislek, saj se je le na tej osnovi mogoče izogniti negativnim družbenim in tudi epistemološkim implikacijam njenega razvoja.

6 Zaključek

V zadnjem času je tako v znanstvenih krogih kot tudi zunaj znanstvenih krogov veliko govora o možnih tveganjih današnjega in prihodnjega razvoja umetne inteligence. Znanstveniki iz Massachusetts Institute of Technology, ene najbolj uglednih akademskih institucij v ZDA, so v letošnjem letu pripravili javno dostopni repozitorij z umetno inteligenco povezanih primerov tveganj. V omenjenem repozitoriju se trenutno nahaja kar 777 opisov takšnih tveganj. To je še en dokaz, kako veliko zanimanje obstaja danes za ta vprašanja. V mojem kratkem prispevku sem se dotaknil zgolj enega izmed teh številnih problemov, ki je vezan bolj na epistemologijo znanstvenega raziskovanja, ne pa toliko na družbene posledice razvoja umetne inteligence. V tem kontekstu me je predvsem zanimalo, ali pospešena raba VJM v okviru različnih znanstveno-raziskovalnih aktivnosti predstavlja eno izmed domen, kjer se na stežaj odpirajo vrata nastopu umetne splošne oziroma umetne super inteligence. Še posebej me je zanimalo vprašanje, zakaj GUI postaja že danes nepogrešljivo »orodje« v seh fazah znanstvenega raziskovanja. V sklepnem delu sem se na kratko ustavil ob nekaterih specifičnih dilemah uporabe GUI na področju družboslovnega raziskovanja.

ABSTRACT

In this paper, we examine the academic performance of students in different courses to determine whether good performance in one course is related to good performance in other courses. Although certain predictive models emphasize the importance of course content for learning success, there are few studies that address how student performance in different courses is related to similar course topics, learning goals, competences, and skills. By creating a preliminary framework that examines how academic performance is related to different course topics, we attempt to make a first step further towards addressing the research gap regarding the interrelatedness of student achievement not only in different course topics but in different competence areas. We examined a set of student grades from eleven different courses at the faculty from areas such as entrepreneurship, management and leadership, business informatics, mathematics, economics, marketing and market analysis, innovation and creativity, English, finance and accounting, business law, and human resource management. We show that students with more exam retakes on average reached a lower grade rank than the students who only registered for the exam once. We used linear regression to show the significance of the relationships between student performance in the Informatics course compared to their achievement in other courses. With a correlation matrix coefficient, we measured the strength of reciprocal interrelatedness between the grade ranks students attained in each of the eleven courses. The results of this preliminary study indicate a possible stronger association between academic achievement in courses that have similarities in terms of content or focus, such as business administration and entrepreneurship (correlation coefficient of 0.58). Further studies with detailed comparison of course-specific competences are needed for accepting the finding that interrelatedness between achievements in courses from similar versus different disciplines is stronger. The preliminary model could further be improved by a broader range of courses, input explanatory student factors, and application of advanced analytical techniques.

KEYWORDS

course-specific competence, learning analytics, prediction models, student academic achievement, student academic performance

1 INTRODUCTION AND RELATED WORK

Are students who achieve excellent results in one course more likely to achieve outstanding results in another? And vice versa? This is the key question that triggered this preliminary research into how students perform in different courses. As a result, we are examining the relationships between students' academic achievement in different courses from two different undergraduate study programs at the faculty of entrepreneurship. Despite some prediction models suggesting the course content as one of the input explanatory variables, there is a significant lack of detailed research on the relationship between students' achievement in different courses from the same, similar, or entirely different discipline. Therefore, this preliminary study aims to develop a pilot model to investigate the relationship between academic success in various courses and their respective course topics. The findings of this study could be further reinforced and interpreted by the comparison of course-specific competences and learning objectives.

Apart from the prediction model of academic achievement, interrelatedness between academic achievement in different courses compared to the course main topics, competences, and learning objectives is still largely missing. Since previous studies that would previously investigate the interrelatedness of student achievement in different courses are, to the best of our knowledge, entirely nonexistent, let us draw attention to the research studies that are related to the field and that have led to this investigation. OECD [12, 13], for example, show a positive association between literacy and numeracy skills. Moreover, in our previous research [2], we showed that students who achieved better academic achievement in word skills were on average also more likely to achieve better achievement in excel skills. However, this does not imply that it is sufficient to develop only some of these skills, such as solely including word skills, excel skills, literacy skills, or just numeracy skills in the curriculum. Furthermore, this does not imply that students in a real situation cannot achieve much better results in a certain type of skill compared to another. Additionally, Fink and Vadnjal [3] conducted a pilot study that compared the development of

generic and course-specific competences during a higher education course.

As previously mentioned, one could apply findings about the relationships between various course topics, contents, competences, or objectives to the development of predictive models and predictive algorithms. Prediction models are often used to find out ahead of time which students are likely to drop out or fail external exams. The schools aim to take intervention measures and steps to stop the bad predictions from coming true, and the success rate can be raised [16, 9]. There are a lot of different input explanatory variables that can have a big effect on how well and especially how accurately prediction models perform [16, 4, 7, 8, 9, 11, 1]. Some prediction models include related concepts to the course content [7], such as the course's learning objective, the course's main competences, the course topic [4], or even course preparedness [10].

In addition to the combination of input explanatory variables, various statistical methodologies and techniques, as well as different types of measurements and academic achievements, significantly influence the prediction model's power and performance. While adding additional or all relevant factors to the model does not always improve its performance, the right combination of input explanatory variables significantly influences the accuracy and other model performance measures [4]. In the end, the right combination of input variables largely determines the model's explanatory power, the accuracy of its predictions, and other performance measures [6, 15].

Different prediction models are based on different methodologies and include different input and output variables. Francis and Babu [4], for example, compare prediction models of student achievement that include the topic of the course as the input explanatory variable. They demonstrated that the course topic, along with many other factors, is one of the explanatory variables for academic achievement. However, their model found that academic factors, including the course topic, were less accurate in predicting students' academic achievement than demographic factors, behavior factors, and other factors such as absence days, parental satisfaction, and school survey responses. They developed, compared, and assessed performance measures of several prediction models. The model that included academic factors, behavior, and additional input explanatory variables showed the greatest improvement in accuracy. On the other hand, adding demographic factors on top of that reduced the accuracy of academic achievement prediction. Clearly, the addition of additional input variables, for example, the topic of the course, in different models contributes differently to improving prediction accuracy and other performance measures, depending on other input variables in the model.

2 HYPOTHESES

In this preliminary study, we aim to build a preliminary pilot research model on which we will test the interrelatedness between academic achievement in different courses. We suggest the following hypotheses:

H1. Mostly there are reciprocal relationships between a student's performance in one course and their performance in another.

H2. As the number of exam retakes increases, the student's grade rank decreases.

3 DATASET AND METHODOLOGY

The dataset collection and preparation included several phases. First, we have collected students' grades for different courses at the higher education institution. The initial dataset included the grades of 223 students for 67 different courses.

In the second phase, we have refined and further prepared the dataset. Based on some simple data exploration and visualization techniques, such as plotting the missing values, plotting the distribution of the number of grades available per course, and plotting the distribution of the number of exam retakes per course, we have decided to eliminate the data of courses with less than 60 students' grades per course. With that, we narrowed further analysis to the following eleven selected courses: Business Economics, Informatics, Management and Leadership, Marketing and Market Analysis, Entrepreneurship, Business English, Accounting, Creativity and Innovation, Business Mathematics and Statistics, Business Law, and Human Resource Management.

Table 1: Number of grades per one and two courses

Course (Short name)	Nr. of students/grades	
	per course	for chosen course and Informatics (%)
Informatics for entrepreneurs (P07_IE)	160	
Business economics (P05_BE)	139	120 (86 %)
Business law for entrepreneurs (P06_BLE)	79	71 (90 %)
Human resource management (P09_HRM)	66	58 (88%)
Management and leadership (P15_ML)	156	142 (91%)
Marketing and market analysis (P16_MMA)	90	73 (81%)
Entrepreneurship (P27_ENT)	191	148 (77%)
Business English (P28_BE)	152	133 (88%)
Accounting for entrepreneurs (P33_AE)	143	131 (92%)
Creativity and innovation in entrepreneurship (P36_CIE)	173	142 (82%)
Business mathematics and statistics (P39_BMS)	139	119 (86%)

We then compared the number of students' grades available per one course with the number of grades available per two courses (the selected course and the informatics) and calculated the share of students that also took the exam in informatics

compared to the number of students who took the exam in the selected course only. Students' grades include both those that indicate a student has passed the course and those that indicate a student has not. Since we included only one grade per student in further analysis, the number of students' grades reflects the number of students who took the exam in each course. Not all students took exams in all eleven subjects. The reasons for this are varied, including the fact that the courses are from two different programs.

The courses with the highest student grades include Entrepreneurship (191), followed by Creativity/Innovation (173) and Informatics (160) (Table 1). More than 77% of students (148) who took the entrepreneurship exam also took the informatics exam. Similarly, 82% of students who took the exam in creativity/innovation (142), and 91% of those who took the exam in management/leadership (142) also took the exam in informatics. In other words, students who attended the exam in the Informatics course often also attended the exam in the Entrepreneurship, Management/Leadership, and Creativity/Innovation courses, as shown in Table 1.

Then, we continued by calculating the average grade ranks and number of exam retakes (table 2) for each of the courses included in the analysis. The grade ranks range from 0 to 10, where 0 represents not attending, 1 to 5 represents failed, 6 satisfactory, 7 average, 8 good, 9 very good, and 10 excellent. As shown in Table 2, the students on average achieved better grades in the HRM course than in other courses. In comparison, the students on average achieved the lowest average grade rank in the Mathematics/Statistics and Economics course compared to other courses. The students also, on average, most commonly retook the exam in these two courses. Additionally, we found that 38 students attended at least one exam deadline for each of the eleven courses.

Table 2: Average grade rank and number of exam retakes

Course (Short name)	Avg. grade	Avg. nr. of retakes
Informatics for entrepreneurs (P07_IE)	7.7	1.2
Business economics (P05_BE)	6.6	1.8
Business law for entrepreneurs (P06_BLE)	7.1	1.3
Human resource management (P09_HRM)	8.0	1.1
Management and leadership (P15_ML)	7.3	1.2
Marketing and market analysis (P16_MMA)	7.5	1.3
Entrepreneurship (P27_ENT)	7.4	1.3
Business English (P28_BE)	7.3	1.2
Accounting for entrepreneurs (P33_AE)	7.0	1.3
Creativity and innovation in entrepreneurship (P36_CIE)	7.2	1.3
Business mathematics and statistics (P39_BMS)	6.4	2.0

In the third phase, we continued with the data exploration and visualization. We plotted the distribution of the number of grades achieved per grade rank for each of the selected eleven courses. An example of the distribution for the Entrepreneurship course is provided in Figure 1.

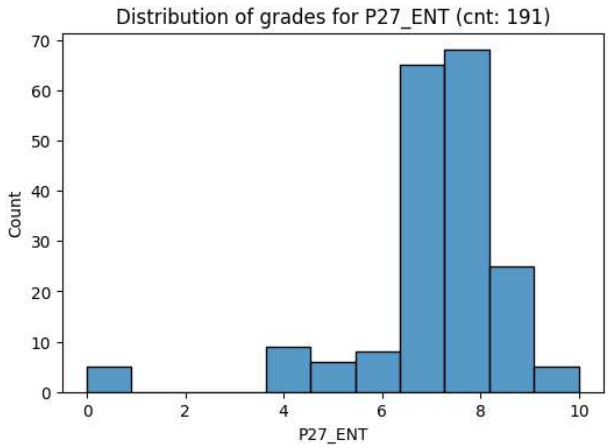

Figure 1: Distribution of number of grades per each grade rank for Entrepreneurship course example

In the next phase, we focused our investigation on how the grades that students achieved in the Informatics course behave compared to the grades they achieved in the remaining ten courses. We performed and visualized ten linear regression models describing the relationships between grade ranks students achieved in the informatics course and the grade ranks students achieved in other selected courses. When performing the linear regression, we included the grade rank achieved in informatics as an independent variable. Though we are aware that linear regression models assume the influence of the independent variable on the dependent variable and not the reciprocal relationships per se, we decided to mention this limitation and work further with the results obtained from the regression analyses in this preliminary pilot study.

We performed additional analysis based on the correlation matrix between the grade ranks students achieved in each of the eleven selected courses. We draw a correlation matrix with significant ($p < 0.05$) correlations among regression coefficients between the eleven selected courses to determine which of the eleven courses is related to another one. We then examined the strength and significance of the reciprocal relationship that the correlation matrix coefficient measures.

Next, we further compared the characteristics of our data for the selected eleven courses with the characteristics of the data for all the courses. We used data visualization techniques such as plotting to compare the distribution of the average grade of eleven selected courses and all the courses. The distribution of average grade for the selected eleven courses seems fairly similar to the distribution of average grade for all the courses, as shown in Figure 2.

Although we cannot claim that an analysis of the entire data set would yield similar results to the analysis of the selected eleven courses based solely on the similar distribution of average

grades, we cannot completely rule out the possibility that on average, somewhat similar associations would emerge among the other courses.

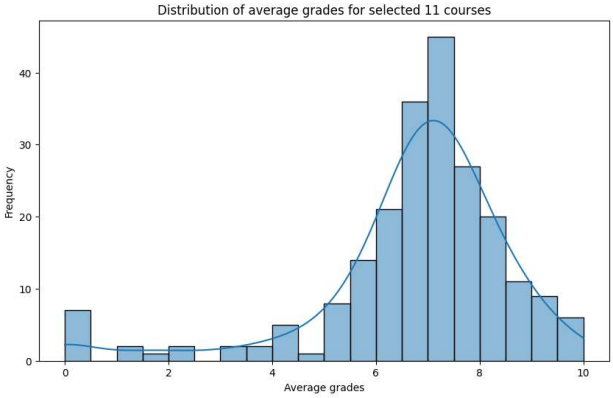

Figure 2: Distribution of number of grades per each grade rank per course example

In the final phase of this preliminary pilot research, we performed the regression analysis between the grade rank that the student achieved and the number of exam retakes of the student.

4 RESEARCH FINDINGS

The eleven selected courses served as the basis for the analysis, which focused on identifying reciprocal relationships between the grade ranks of one course and those of another course. We selected the courses based on the number of grades available after exploring, visualizing, cleaning, and refining the data. In addition to linear regression models, we calculated the correlation matrix's correlations (Figure 3) that investigate the reciprocal association between the grade ranks students achieved in one course compared to another.

Overall, we investigated 55 reciprocal relationships (H1) between the grade ranks of one course with the grade ranks of another course. Among these, forty-six correlations are significant ($p < 0.05$) compared to nine correlations that are not significant. Among the significant correlations, nine correlation coefficients exhibit a moderate relationship (between 0.5 and 0.7) between the grade ranks of one course and the grade ranks of another course. Twenty-seven correlations show a weak correlation (between 0.3 and 0.5), while ten correlations show a negligible or low correlation (below 0.3) between the grade ranks of two selected courses.

The strength of significant coefficients varies from 0.19 all the way up to 0.58. Many of the coefficients that we would otherwise have placed in the group of weak correlations are very close to 0.5, which indicates moderate correlation. There are also many coefficients that we have otherwise placed in the group of negligible correlations close to the value of 0.3, which indicates a weak correlation.

Based on these results, we can accept hypothesis 1 that foresees the existence of reciprocal relationships between a student's performance in one course and their performance in another in most cases when comparing different pairs of courses.

Let's examine the concrete correlations between the grades of the two courses. There is a moderate correlation between Economics and Mathematics/Statistics (0.60), followed by Economics and Entrepreneurship (0.58), Informatics and Mathematics/Statistics (0.57), Marketing/Market Analysis and Law (0.57), Marketing/Market Analysis and Entrepreneurship (0.55), Economics and Accounting (0.54), Marketing/Market Analysis and Creativity/Innovation (0.52), and Economics and Informatics (0.51), and Informatics and Marketing/Market analysis (0.50).

Based on moderate correlations, we can speculate that Economics, Informatics, Mathematics, and Accounting courses are closely connected, partially because students have to use the numeracy skills in these courses. Therefore, future research could address the question of whether the syllabus of these courses reflects shared similar competences. Although rare, previous research [12, 13] on the interrelatedness of competences has shown that people who are more proficient in literacy skills are usually also more proficient in numeracy skills, and vice versa, additional inquiry into the similar and different competences that are developed within these courses would provide an important insight and more thoroughly address the gap in the literature on the interrelatedness between competences that is largely still missing. Therefore, we also need to investigate further to what degree are the numeracy skills included in the syllabus of the courses that otherwise aim at developing soft, social, and other professional skills, such as the Entrepreneurship and Marketing/Market Analysis courses. Additionally, based on the analysis, it would also make sense to check whether the Marketing/Market Analysis and Creativity/Innovation courses foster the development of related skills. In general, we can speculate that the type of competences is important for student achievement, but to confirm this, we would have to perform the qualitative analysis of the similar competences and learning objectives in the future.

The majority of the relationships are statistically significant but weak. Weak correlation exists between Entrepreneurship and Mathematics/Statistics (0.49), Entrepreneurship and Informatics (0.47), Economics and Management/Leadership (0.47), Entrepreneurship and Law (0.45), English and Entrepreneurship (0.45), Economics and English (0.43), Creativity/Innovation and Entrepreneurship (0.42), HRM and Law (0.41), Accounting and HRM (0.41), Informatics and Accounting (0.41), Management/Leadership and Accounting (0.40), English and Mathematics/Statistics (0.38), Mathematics/Statistics and Law (0.38), Marketing/Market Analysis and Law (0.37), English and Accounting (0.37), Management/Leadership and English (0.36), Entrepreneurship and HRM (0.36), Law and Economics (0.34), Management/Leadership and Entrepreneurship (0.34), Entrepreneurship and Accounting (0.33), Accounting and Mathematics/Statistics (0.33), Management/Leadership and Marketing/Market Analysis (0.31), Marketing/Market Analysis and Economics (0.31), Management/Leadership and Law (0.31), Informatics and Law (0.30), English and HRM (0.30), Creativity/Innovation and Accounting (0.30).

A low correlation below 0.3 exists between Accounting and Law (0.29), Marketing/Market Analysis and English (0.29), Marketing/Market Analysis and Accounting (0.28), Economics

and Creativity/Innovation (0.27), Informatics and Management/Leadership (0.26), Management/Leadership and Creativity/Innovation (0.25), Management/Leadership and Mathematics/Statistics (0.25), English and Informatics (0.22), English and Creativity/Innovation (0.20), and Creativity/Innovation and Mathematics/Statistics (0.19).

Based on the weak and low correlations, we can speculate that these correlations exist in courses that do not necessarily share that much of similar competences and learning objectives as those that exhibit moderate correlations. As mentioned previously, further qualitative research is required to substantiate these assumptions.

Since not all students took the exams in all the courses, the number of observed instances for each pair of two courses ranges from 46 to 166, depending on the particular pair of courses. Not only that, we found that the low number of observed instances importantly contributed to the statistical insignificance of some correlation coefficients. The relationships calculated based on a low number of observed instances, such as, for example, between Mathematics/Statistics and Law (46 observed instances), Marketing/Market Analysis and Mathematics/Statistics (46), HRM and Economics (47), Informatics and HRM (58), English and Law (58), Management/Leadership and HRM (59), and Creativity/Innovation and HRM (59 observed instances), exhibit insignificant relationships. The exemptions are the insignificant relationship between the Informatics and Creativity/Innovation course with 142 observed instances and between the Creativity/Innovation and Law course with 74 observed instances. We therefore speculate that the Informatics and Law courses strive to develop different competences than the Creativity/Innovation course. This preliminary analysis is a useful basis for further research and analysis.

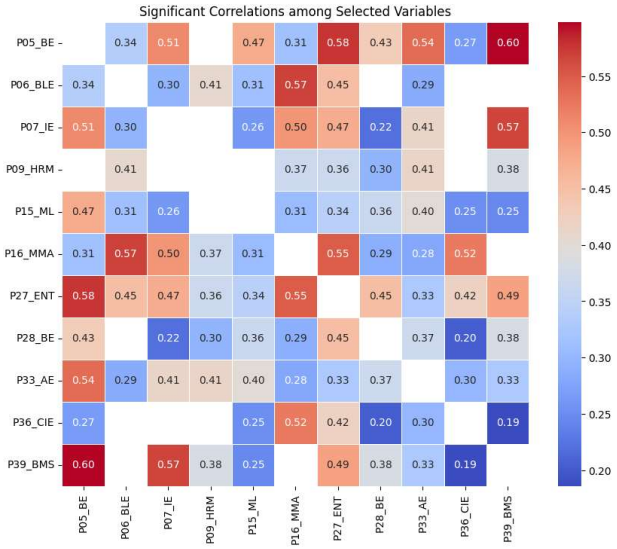

Figure 3: Correlation matrix with significant correlations

The results of the regression analysis between the grade rank that the student achieved and the number of exam retakes that the student took (H2), that are shown in Figure 4, suggest that the students with more exam retakes on average reached a lower grade rank than the students who only registered for the exam once (β = -0.47, p = 0.00). The full equation is displayed below (equation 1). Based on these results, we accept hypothesis 2 that as the number of exam retakes increases, the student's grade rank decreases.

$$Grade\ rank = 8.25 - 0.47 * Nr.of\ exam\ retakes + residuals \quad (1)$$

Figure 4 also shows that most students register for the exam once, fewer students register for the exam twice, and even fewer students register for the exam a third time.

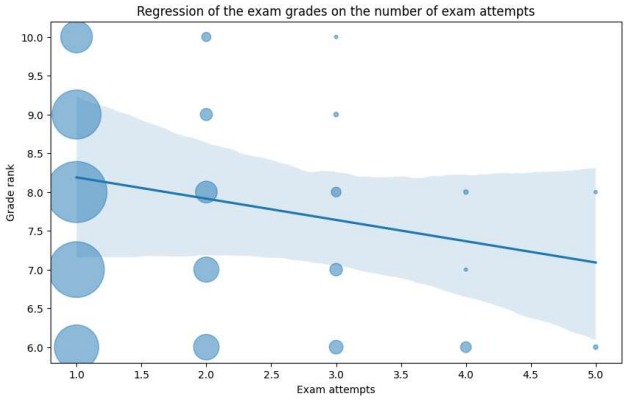

Figure 4: Regression analysis between number of exam retakes and average grade achieved

5 CONCLUSION

The purpose of this study was to lay the groundwork for further research regarding the correlation between different course-specific competences and to present initial findings regarding the correlation between students' academic achievement in different courses. In this paper, we aim to enhance our comprehension of the intricate relationship between competences, an area that remains largely unexplored. The preliminary analysis revealed the existence of interrelatedness among grades students achieve in different courses, and showed that a student's academic performance in one course influences their performance in another. Based on the analysis we accept hypothesis 1 that foresees the existence of reciprocal relationships between a student's performance in one course and their performance in another in most cases when comparing different pairs of courses. We also show that students with more exam retakes on average reached a lower grade rank than the students who only registered for the exam once. With that, we accept hypothesis 2 that as the number of exam retakes increases, the student's grade rank decreases.

To determine whether there is a stronger correlation between academic achievements in courses from the same or similar

discipline than in courses from completely different disciplines, further research is required to explore how much the interrelatedness between courses depends on the competences, learning goals, and discipline of the course.

Since this is a preliminary pilot analysis, we considered additional opportunities to improve our research in the future. We could enhance this study by utilizing additional methods, such as cluster analysis, network analysis, and structural equation modeling, along with techniques used to make predictions like data mining [11, 1], neural networks [5], or decision trees [14]. Furthermore, we could enrich the model by increasing the number of observations and the number of courses included in the analysis.

To capture more subtleties in these relationships, we could potentially build and test the model's performance with additional input variables such as information about general knowledge, broad outlook, ambitions, and psychological characteristics. Additionally, we could compare different cohorts of students, the semester, the study program and track, forms of study (full-time, part-time), types of study programs (undergraduate, postgraduate, higher vocational program), and study modes (classroom, blended, online).

Linking the Normative and the Descriptive: Bounded Epistemic Rationality

Nastja Tomat†

Abstract

Epistemic rationality is a type of rationality directed towards cognitive or epistemic goals, such as true beliefs, knowledge, or understanding. Epistemology is primarily concerned with normative questions about how one should form and update beliefs, reason and inquire to be rational; on the other hand, empirical disciplines, such as psychology, investigate how inquiries and belief formation occur in real life. The question arises as to what the relationship between the normative and the descriptive in the study of epistemic rationality should be. This paper proposes a notion of bounded epistemic rationality as a hybrid, non-ideal concept that encompasses both normative and descriptive elements. Drawing upon Herbert Simon's bounded rationality and Robin McKenna's non-ideal epistemology, bounded epistemic rationality is characterized by requiring satisficing instead of maximizing; acknowledging our cognitive, environmental, and practical limitations; its ecological nature; and its focus on the process of inquiry. As such, bounded epistemic rationality is a good starting point for proposing epistemic advice that is achievable for real cognizers and helps them improve their epistemic position.

1 Introduction

Epistemic rationality is one of the main topics of epistemology. It refers to epistemic attitudes, states, and processes [1], mainly focusing on rationality of beliefs, and is directed towards reaching cognitive or epistemic goals, such as true beliefs, knowledge, or understanding [2, 3, 4]. One of the central tasks of epistemology has been to propose epistemic norms about how one should form, update and revise beliefs to be rational. Although it is acknowledged that humans are not ideal agents – there is ample empirical evidence, gathered by disciplines as cognitive psychology, showing that we are limited by our cognitive architecture and the nature of cognitive processes, such as computational power and speed, predictive abilities, working memory and attention [5, 6, 7] – traditional analytic epistemology still often relies on idealized models of human cognizers [8], with the consequence that it frequently imposes epistemic norms such as logical omniscience, consistency between beliefs, and immediate updating of beliefs by conditionalization [9].

Philosophy, including epistemology, is predominantly concerned with the normative questions about justification, rationality and other epistemic appraisals of our cognitive activities and doxastic states, while empirical disciplines, such as psychology, empirically investigate how human cognition, inquiries and belief formation occur in everyday life. With normative theories on the one hand and empirical research on the other, we are faced with the question of the relationship between the two approaches towards studying rationality.

The aim of the paper is to propose a concept of bounded epistemic rationality as a hybrid notion that may help us bridge the gap between the normative and the descriptive. By adopting a concept that is – to some extent – grounded on empirical data about human cognition but does not dispose with the normative questions about epistemically good cognition, we can propose epistemic norms and epistemic advice that are achievable for real human cognizers and can help them improve their epistemic situation.

2 Normative and descriptive theories of rationality

Philosophical understanding of rationality is deeply intertwined with the notion of normativity. There are different views on how to define and justify epistemic normativity and which epistemic norms we should endorse. We can understand rationality as a system of rules or requirements: it requires from us, for example, not to hold contradictory beliefs, to draw a conclusion by modus ponens [10], to have deductive closure [11], or to follow rules of logic, probability and decision theory [12]. Rationality is thus normative in the sense of employing certain norms and rules according to which we can judge correctness of a belief [13]. Nevertheless, a genuine normative question of rationality requires us to determine if those rules or requirements are necessarily accompanied by a reason to conform to them, or, in other words, if we *ought* to conform to them [13, 14].

In addition to the debate about genuine normativity of rationality, there is an ongoing discussion about how epistemic norms or principles should be formulated and what they should prescribe. According to Engel, there are some conditions such principles should satisfy to be genuinely normative: they should have normative force, a potential to regulate or direct our inquiry and beliefs, and normative freedom – a possibility to be violated. If we accept these conditions, many normative principles that are often employed are not adequate. A rule that says, for example, that one should not believe p and not p, tells us something about a characteristic of a rational belief, but gives us no guidance on how to achieve it [11]. Such rules are more of a description of a belief or believer in ideal conditions than genuine normative principles. A similar point is put forward by Robin McKenna in his book Non-ideal epistemology [8]. He claims that mainstream epistemology mostly proposes epistemic norms based on various types of idealizations, for example about cognitive capacities of epistemic agents and the nature of epistemic environment. He calls such an approach to epistemological theorizing ideal epistemology and contrasts it with non-ideal epistemology which tries to avoid such idealizations. The issue with the norms proposed by ideal epistemology is that they are too detached from real world issues, too demanding and unachievable for real human cognizers. Another, even more important issue is that they provide bad epistemic advice: if we try to achieve or approximate proposed ideals and norms, we will often worsen rather than improve our epistemic situation. McKenna uses an example of the ideal of objectivity in scientific inquiry: trying to achieve objectivity as detachment – in a sense that scientists are not personally invested and interested in the topic of inquiry and try to detach research process from non-cognitive values – leads to worse, not better, scientific inquiry. McKenna draws on Elizabeth Anderson's work on value judgements in science. She argues that researchers' background assumptions and values influence all the stages of research process – they partly determine how we frame the research questions, conceive of the object of inquiry, what data we collect, how we analyze and interpret them. A large portion of empirical research in social science investigates evaluative questions that are related to well-being of individuals, social groups or society at large, and science that is legitimately guided by certain, for example feminist values, could be more fruitful and more likely lead to desired epistemic goals. Instead of trying to be attain an ideal of objectivity, scientific inquiry should be informed by the right values [15]. A similar argument can be made for our everyday inquiries: if we, for example, always aim to reason in accordance with a norm proposed by ideal theory, such as logic and probability theory, or trying to think in intellectually autonomous way instead of relying on experts, this will likely lead to worse epistemic outcomes than using less complex, heuristic processes or form a belief according to the consensus of the experts [16]. This means that ideal theory is failing as a normative theory because its prescriptions often do not help us achieve our epistemic goals, such as obtaining true beliefs, knowledge or understanding, and cannot serve as regulative ideals. For this reason, the ideal approach should in certain situations be replaced by a non-ideal one [8]. Both Engel and McKenna emphasize that an important feature of epistemic norms is their potential for guidance, for improving our inquiries, reasoning, and forming beliefs that are in some way epistemically better. Instead on focusing on defining conditions for epistemic ideals such as justification and knowledge and engaging in "S knows P iff …" kind of epistemology, McKenna claims that we should engage in non-ideal theorizing that is informed by empirical literature on human cognition, knowledge-producing institutions and epistemic environment. While McKenna claims that descriptive questions should be a starting point for answering normative questions, he does not argue for a strong form of naturalism or for the replacement of epistemology by empirical science, but merely suggests that there should be a closer connection between epistemology and empirical disciplines than is currently the case [8]. The norms that non-ideal epistemology proposes would therefore be norms of inquiry that help agents determine which problems are important to inquire about in the first place; how to collect, assess and evaluate evidence; what to do when they are presented with conflicting information; how to identify trustworthy and reliable sources of information; and when they gathered enough evidence to terminate an inquiry and form a belief. Instead of a norm stating something in terms of "a belief about whether anthropogenic climate change is real is rational if it is achieved in a reliable manner and responsive to the available evidence", non-ideal epistemology would propose norms specifying what is an epistemically good manner in which ordinary laypeople should gather evidence about climate change, how to identify genuine experts and how to recognize good evidence. Such norms would require inquiring in a way that is possible for ordinary people – would not, for example, require enormous amount of time and philosophical understanding of the concept of evidence – and would be based on empirical data on which ways are effective for gaining true beliefs about climate change – for example, relying on science marketing strategies [8]. Such norms or principles would satisfy Engel's conditions and could thus be considered as genuinely normative.

3 Bounded rationality

Although many authors who investigate rationality or epistemic norms explicitly acknowledge that humans are limited agents and that our boundaries should put a constraint on epistemic norms, only a few philosophers have drawn on the notion of bounded rationality. Bounded rationality was introduced by political scientist Herbert A. Simon and has importantly influenced many disciplines investigating rationality, such as psychology and economics. Simon argued that global, idealized theories of rationality should be replaced with a notion of rationality that is compatible with cognitive capacities of the subjects and the features of the environment in which they are embedded. As our cognitive capacities, for example predictive and computational capabilities, working memory and attention, are limited, human rationality can be only an approximation of an ideal rationality that is assumed in models of decision theory. If we want to comprehend human rationality, we should not focus only on internal characteristics of human cognition, but also on the structure of the environment. Simon illustrated this with a metaphor of scissors: "Human rational behaviour (and the rational behaviour of all physical symbol systems) is shaped by a scissors whose two blades are the structure of task environments and the computational capabilities of the actor." [17, p.7]. Simon argued that human rationality was satisficing, not optimizing – meaning that humans do not seek for best

possible solutions of a problem or best possible outcome of a decision situation, but for solutions that are merely good enough – and he urged to dispose of the notion of optimization as a criterion for rationality. He also emphasized that bounded rationality is procedural, meaning that it does not focus solely on the outcomes, but also on the process leading to them; an agent is therefore rational if her behavior stems from an appropriate process of deliberation [17-21].

4 Bounded epistemic rationality

According to Sturm [22], philosophical aspects of bounded rationality have not yet been systematically investigated; nevertheless, the role of bounded rationality in epistemology has recently been explored by David Thorstad [7]. He describes five characteristics of bounded rationality as a paradigm, the first one being that bounds are important. As opposed to practical philosophy where it is universally acknowledged that our physical limitations put constraints on the norms of rational action, this is not necessarily the case for epistemic rationality. Thorstad claims that bounds are equally important for our understanding of rational cognition than of rational action and that we should be normatively required to perform only those cognitive operations that we are capable of. Secondly, theories of rationality should consider not only the final beliefs and other doxastic states, but also the processes that led to them, which is directly derived from Simon's notion on procedural nature of bounded rationality. The third and fourth characteristics refer to the claim that rationality is not bound only by our cognition, but also by environmental factors and that the use of rules of thumb or heuristics can be more rational than using more complex reasoning strategies. Drawing on the work of Gerd Gigerenzer and ecological rationality [6, 16], Thorstad claims that heuristics may in many situations or environments provide more accurate predictions than other, more sophisticated strategies. Finally, bounded rationality is compatible with a so-called programme of vindicatory epistemology, which states that what we usually consider as a violation of rationality norms is a consequence of a deliberation process that is merely boundedly rational. Although we do not comply with traditional epistemic norms as coherence and deductive closure, we are often inquiring and reasoning in the most rational way possible considering our limitations.

Drawing on Thorstad's work, I propose and expand on several characteristics I believe should be incorporated in the account of bounded epistemic rationality. First, bounded epistemic rationality is distinctively epistemic in a sense that it is directed towards cognitive or epistemic goals, regardless of which specific goal we are committed to – having true beliefs and not having false beliefs, making accurate predictions, gaining knowledge or understanding. At the same time, bounded epistemic rationality does not require optimal solutions, but solutions that are merely good enough - it doesn't require from cognizers that their predictions are a hundred percent accurate or that they possess all and only true beliefs about trivial topics that are not relevant to them. Nevertheless, an account of bounded epistemic rationality will need to provide criteria for how to decide if a belief or a prediction is epistemically good enough – be it true, accurate or rational enough. I believe this can be done in one of three ways. The first option is to claim that by acquiring beliefs that are not true (in a sense of a truth requirement usually imposed by veritism), but are approximations, simplifications, or generalizations, are more conducive to reaching a wide array of other epistemic goals and desiderata that are perhaps even more valuable than truth, such as in-depth understanding of phenomena [23, 24]. The second option is to introduce a non-epistemic criterion for "good enough." A belief is rational enough if it helps us select appropriate actions for achieving some other, non-epistemic goal that we intrinsically value; in this case, a belief is good enough if it has instrumental value. The third option is that "good enough" is partly determined by pragmatic criteria, but the goal remains epistemic. This is in line with the thesis of pragmatic encroachment which claims that epistemic status of a belief is not determined solely by epistemic, but also by pragmatic factors. A certain belief may be considered good enough if, for example, the consequences of the belief being false are not vast.

Second, bounded epistemic rationality acknowledges that we are bounded by our cognitive capacities, the nature of the environment in which we operate, and by practical considerations of our daily lives. It considers that we have limited processing power, attention span, working memory, predictive abilities and so on and employs ought-implies-can principle of normativity: things that are normatively required from cognizers are only those which they are in principle capable of executing. Furthermore, it considers the features of our epistemic environment, especially the nature and structure of available information. Levy [25], for example, speaks of so-called polluted epistemic environments, which consist of a large portion of misinformation and where various individuals and institutions imitate the criteria of expertise, making it difficult for laypeople to identify reliable sources of information and genuine expertise. In such environments, false beliefs cannot be attributed primarily to the lack of epistemic virtue or irrationality of a cognizer but must be understood in the context of epistemic environment. Finally, bounded epistemic rationality considers that we have limited time and cognitive resources that we can devote to a certain task. Our inquiries do not happen in a bubble that detaches us from our practical considerations – in everyday life, we cannot afford to infinitely inquire about a certain topic, even if it is highly relevant and interesting for us. Bounded epistemic rationality does not require us to inquire and form beliefs in a way that would demand postponing all other activities in life. Acknowledging that practical factors should to some extent play a role in epistemic requirements is compatible with a view put forward by Bishop and Trout [26, 27]. In their theory of strategic reliabilism they urge that epistemological theories should include both epistemic and pragmatic factors, and they see epistemically good reasoning as "reliable, cost-effective, and focused on significant problems" [26, p. 106].

Third, bounded epistemic rationality is not defined by adherence to a rigid system of highly demanding, idealized rules or requirements, but by a fit between the strategy and the environment. Therefore, various strategies, from complex reasoning to simple heuristics, can be rational as long as they are conducive to certain epistemic goals; for the moment, I leave open whether this should be truth, prediction, knowledge, or understanding. Bounded epistemic rationality is thus

consequentialist, as it promotes a form of cognitive success [28], and ecological, as it emphasizes the fit between a strategy and the task [6, 16].

Fourth, bounded epistemic rationality does not focus on the final doxastic states, but on the process of inquiry. This is compatible with a so-called zetetic turn in epistemology: in recent years, epistemologists have started to move away from identifying conditions for knowledge and justification towards the questions about what good inquiry should look like – for example, when to start and stop inquiring and how to collect and evaluate evidence [29, 30]. Focusing on the process of inquiry has more potential for providing epistemic advice than focusing solely on the descriptions of epistemic ideals, such as knowledge. Although describing the conditions for knowledge and justification are crucial parts of epistemology, combining this project with a program of inquiry epistemology could be more fruitful for providing epistemic guidance helping inquirers in achieving epistemic goals. A notion of bounded epistemic rationality is therefore compatible with a project of ameliorative or regulative epistemology [27, 31]. As a non-ideal concept that considers real-life characteristics of our cognition and epistemic environment, it can give advice that is applicable to ordinary inquirers – for example, what to do when faced with contradictory evidence; when should we stop gathering evidence and form a belief; when epistemic environment is so polluted that it may be rational to suspend judgement; how to judge which sources are reliable and trustworthy and so on.

4.1 Norms of bounded epistemic rationality

A crucial question regarding the norms of bounded epistemic rationality is in what way they should relate to empirical science, specifically psychology. Norms of rationality cannot be directly derived from empirical data, as this would mean committing *is-ought* fallacy [32] – we cannot infer how one ought to reason from descriptive premises about how we do reason. Nonetheless, psychological data on human cognition can at least serve as constraints showing us what is realistic to expect from cognizers.

Another question concerning the norms of bounded epistemic rationality relates to the notion of adaptability. Since it is an epistemic notion, bounded epistemic rationality must be directed towards epistemic goals, but the question arises whether epistemic goals can in any way be connected to adaptive or pragmatic goals. We might consider a person, belief, or process to be boundedly epistemically rational if it leads to an epistemic goal while functioning as an adaptive response to the environment.

Achieving epistemic goals often helps us to respond efficiently to the environment and therefore has an adaptive function. Even though the intrinsic value of truth may be debatable, it is hard to deny that truth has at least an instrumental value. Nevertheless, there are many situations in which epistemic and adaptive goals may diverge; for example, if someone devotes all their time and resources to researching a complex topic of their interest and neglects all other activities in life, we cannot consider this adaptive. The norms of bounded epistemic rationality should therefore include a notion of adaptability – but not in the sense that adaptive or pragmatic goals can override epistemic ones, but in the sense that they require epistemic goals that are achievable for real human cognizers, and require inquiries that are not too costly in terms of cognitive resources and time.

5 Conclusion

Bounded epistemic rationality is a hybrid concept that includes both normative and descriptive elements. It aims to avoid idealizations of epistemic agents and their environment and to acknowledge the practical limits of our daily lives. Being a non-ideal concept that relies on empirical data about human cognition and our epistemic environment, it has the potential to suggest norms that serve as epistemic advice and help us achieve our epistemic goals.

Exploring Human Perception Using Virtual Reality

France

Abstract

Immersive technologies have seen a great expansion in the last decade and researchers from several disciplines have focused on exploring virtual reality and the way it can affect human perception. Virtual reality is a unique medium which has the ability to transfer the user from the physical environment to a digitally created illusion of space, events and interactions which mimic real life. In this paper, some basic concepts of perception in virtual reality are introduced, followed by the summary of our research which primarily focused on the perception of virtual agents. Our method is based on the concept of interpersonal distance when people meet in social settings and where the distances they keep between each other signal the nature of their relationship. We studied these distances to evaluate realism, attractiveness and even personality traits of virtual agents in virtual reality. We discuss how our results can give valuable insights into the human mind and how we can use this knowledge for training and rehabilitation applications in virtual reality.

Keywords

virtual reality, perception, virtual agents, proximity

1 Introduction

Virtual Reality (VR) is an immersive environment where people can experience scenarios which mimic physical reality. They can also be engaged in virtual interaction with real people, presented in VR as avatars, or computer-driven representations of real humans. The immersive experience and interaction is a fairly recent phenomenon, providing a plethora of research challenges to solve and questions to explore. For example, how do we create believable virtual environments which will facilitate human interaction and what do peoples' responses to these environments teach us about our mental processes?

There are primarily two types of research domains who use VR in their research. The first, social science, is interested in VR as a highly controllable replica of a real world with the ability to create "ecologically valid experience", i.e. human response which is close to a real-life response, in order to investigate human cognition and transfer of knowledge from virtual to physical reality. The second, computer science, is more interested in keeping human evaluation in the loop to optimise computational power and enhance virtual environments. While the primary goal of the second group is not to explore the human mind, it is an inevitable side effect of their scientific endeavour.

There is, however, a third group of researchers. This group presents a bridge between the social and computer science by exploring the potential of virtual immersive technology to enhance human abilities. Its aim is to understand how the virtual experiences could create new and faster learning procedures, aid in physical and mental health rehabilitation by broadening the scope of what is possible in the physical reality, and perhaps even open up new avenues for human experience, to which we do not yet know the limits of.

The aim of this paper is to present some examples of research in VR, dedicated to the exploration of human perception from both the computer and social science perspective. In order to better place the research topic, general concepts of VR are defined in the first part of this article. In the second part, some of our past studies using VR as a tool to measure human behaviour are presented. Our work mainly revolves around virtual agents, digital representations of humans, who populate a virtual scene in VR and may have simple or complex algorithms to simulate natural behaviour. At the end of the article, some of the implications of our research and how it can help us to understand human mind are discussed.

2 Virtual Reality

While research in Virtual Reality (VR) goes back as early as 1970s, it has witnessed a surge in recent years due to the development of relatively low-cost and ergonomic devices, as well as more effective and powerful graphics rendering technology. Entertainment industry began to launch VR-specific games (e.g., Beat Saber, Half-Life: Alyx), social platforms such as Metaverse [16] are using VR for interaction in online virtual environments, some organisations use VR to raise social and political awareness [17, 19]. Other immersive technologies, such as Augmented Reality and Mixed Reality, began their debut to the broad market around the same time as well. Today, they are commonly addressed with the unifying term Extended Reality (XR).

VR, however, is unlike any other immersive system. The goal of VR is to completely disconnect the user from the physical reality which is different to the aim of other XR systems which do so only partially. Complex VR systems include head-mounted display with positional tracking to create the feeling that the virtual world is surrounding and moving with the user, haptic stimulation, spatial sound, representation of the user's body in the environment, etc. This complexity of the system increases system immersion [27, 20]. If the immersion is high, the user will have the feeling of "existing" in the virtual space, an experience known as "presence" or "place illusion, plausibility" [25, 27]. Other illusions can also be created, most notably the illusion of social presence (a virtual human appears to be alive) [3, 1] and embodiment (our virtual body is perceived as our own body).

2.1 Presence

Presence in VR is the experience of an actual place and the feeling that the virtual events are really happening. Lombard and Ditton elegantly described presence as "the perceptual illusion of nonmediation" [14]. The concept of presence was most famously investigated with the so called "virtual pit" experiment [30, 15,

6], where the participants were standing on the top of a narrow ledge in a virtual room, looking down to another room through a wide gap in the floor. The experimenters [6] could detect changes in galvanic skin response, shaking and loss of balance and the participants reported intense emotional reactions of fear as if they were in real danger of falling.

Several other types of environments and scenarios were used by the researchers to elicit emotions (see [4] for an overview). Apart from research on the concept of presence, training and rehabilitation applications were developed in VR to exploit this ability of a virtual environment to induce realistic responses in people. Related to the pit experiment, for example, assessment of construction workers for their postural stability at different heights have been developed [7], and in psychotherapy, similar environments are used to gradually expose acrophobia patients to increasing levels of height [13].

2.2 Social Presence

Social presence is the illusion of being present with another in a virtual environment, or simply the "sense of being with another" [3]. The definition is broad and sometimes other terms are used to define similar or related constructs, such as telepresence, co-presence [21], and plausibility [27]. In VR, the term social presence is more commonly used to denote the level of believability of a co-located virtual human, especially if this virtual human is computer-driven (agent) and we wish to evaluate its naturalness. Social presence with other users in VR (avatars) can also be investigated to evaluate aspects of the system and the environment, such as ability to represent users with emotional expressions or communication channels (sound, text interface), which enhances the collaboration aspect between the users in the VR environment.

Depending on the definition, different ways of measuring social presence exist. Researchers who agree that social presence is a cognitive construct will typically use questionnaires for evaluation [2], while other researchers prefer to use indirect measures, such as eye-tracking and psychophysiology [27], signs of social influence [28], or task-related behaviour [26, 18].

2.3 Embodiment

Embodiment or the Sense of Embodiment (SeO) is the feeling of possessing the virtual body in VR, which feels like it is "ours," and moves according to our intentions [11]. This illusion is linked to the virtual body in VR for which the movement is driven by the user, wearing a tracking device while his HMD view is centered at the eye-view of the head. If the user observes the movement of his hands and body when immersed in VR, he can develop a sensation that the body is actually his own. This illusion was first documented in real-life studies as the so called rubber hand illusion [10]. The feeling of ownership of an artificial body can develop when receiving synchronous visual input and touch sensation on both the virtual and real hand, with only the virtual hand being visible to the user. The same effect can be reproduced using proprioception (the user observes his virtual arm moving as he is moving his real one). Not only is the SeO enabling a more immersive experience (presence is increased when embodiment is added in VR), the SeO is a testament to the the importance of the role of multimodal input in the embodied experience [11].

The illusion was also explored in creative applications, such as giving the user a sense that they possess a part of a body which they actually do not have in reality, e.g., having a sixth finger [9]. Some researchers also explore the idea of co-sharing of a virtual body, where the agency over one avatar can be shared between two users, e.g. one user possesses the left arm an the other the right, as well as different percentages of possession of the full avatar body [5].

3 Using VR to study the perception of virtual agents

As previously mentioned, agents are computer-driven representations of humans who can possess simple or complex behaviour characteristics. Researchers strive to understand how to increase their naturalness, appeal and interactive abilities and the above mentioned illusions, presence, social presence and embodiment, play an important role in this endeavour. Presence increases the believeability of the scenario with the agent, social presence influences the user to exhibit social behaviour, and embodiment gives us the opportunity to measure user's body position and movement in relation to the agent in the virtual space.

3.1 Proximity

Interpersonal distance or proximity is the minimum distance that people maintain between one another when involved in social interaction. The measure comes from proxemics described by Hall [8] who introduced it as an indicator or comfort and familiarity with other people. Many factors influence how close we will approach another: familiarity, culture, gender, personality, etc. Closer distances reveal trustworthiness and comfort, while further distances can signal mistrust, discomfort or fear of the other. In VR, proximity has been used to explore the social influence of virtual humans [1].

The proximity measure can be expressed simply as the Euclidean distance of the current camera (user) position and the position of central mass of the virtual character in the virtual space. It is important that the user is navigating the environment by natural walking in order to preserve distances comparable to real-life interactions. The proximity tasks can vary. In the passive approach, the user is approached by an agent and is asked to press a button at the precise time they begin to feel uncomfortable with the agent's proximity (see image *a*, Figure 1). With the active approach, the user approaches an agent instead, typically to complete a task, e.g., read the name tag on the agent's chest. In the avoidance task, the agent is an obstacle in the environment and the user avoids it to reach a goal. With active approaches, we can generate and analyse walking trajectory from the positions of the user through time (see image *b*, Figure 1) in terms of walking speed, minimum passing distance, average distance from the obstacle, etc. The avoidance behaviour between real and virtual humans has some differences: clearance distance for virtual agents is larger than real humans [24]. However, factors affecting the proximity were found to be generally similar to the ones in physical reality.

3.2 Previous Research

Some of our most relevant results using proximity are presented in this section. The studies used primarily agents which were highly realistic and had real human motion applied using high-performance motion capture (Vicon) with 53 marker system to track the major joints and location of the body. The VR environments were created with Unreal Engine 4 or 5, and we primarily used HTC Vive with natural locomotion (participants could traverse the environment by walking) to immerse our participants

Figure 1: Examples of our experimental stimuli and measures of proximity: a) passive approach, where the virtual agent approaches the user and signals by pressing a button at the precise moment they feel uncomfortable with the agent. The Euclidean distance between the central mass of the agent and user's head-mounted display is recorded as the value of proximity; b) active approach, where the user (dark-grey character on the right of the image) circumvents the agent while walking through the virtual environment. Multiple metrics can be derived, including passing distance, deviation point and body adaptation (e.g., shoulder rotation).

in the virtual scenario. In all our studies, the participants also possessed a virtual body.

3.2.1 User agency. In Zibrek et al. [31], we were investigating the affect of agency over a virtual character in VR. The users were using the Vive controller to either trigger the character motion (avatar condition) or observe the character (agent condition). Afterwards, users were asked to approach the character to find its name tag that was attached to his chest. The aim was to test whether users will come closer to the agent they previously controlled as opposed to an agent who moved independently. The lack of control over an agent could give the impression he has the ability to have independent and unpredictable behaviour. The results showed that it was not the condition, but the subjectively perceived agency (how much the user actually felt in control of the character) which reduced the proximity, revealing the importance of perceived agency as opposed to designed one.

3.2.2 Gender and attractiveness. In human interaction and VR, people will keep different distances from each other depending on their gender: males will stand further away from males and closer to females. Our study [32] focused on proximity to virtual walkers, where gender could be recognised from motion only, since previous studies using point-light displays found walking motion is rich in gender cues [12]. We were also interested to see if a more attractive motion would decrease the proximity. We designed an experiment, where a virtual agent approached the embodied participant. The agent animation was motion captured from several male and female actors and each motion was displayed individually on the character. Participants used the controller to stop the approaching agent when they felt it was uncomfortably close to them. Our results showed no difference in proximity according to the gender of the character, however, the gender of participants affected proximity (females had larger proximity distances to male users). We also found evidence that greater attractiveness will decrease proximity. This was shown only by rating the attractiveness of the motion of the agent, showing the importance of body motion to infer information about other people.

3.2.3 Agent animation. We approached the perception of motion from the perspective of distinct movement patterns which can be observed on people with neurotic and emotionally stable personality traits [22]. We designed an experiment in VR, using a photo-realistic metro scenario, where we studied the avoidance behaviour of participants when encountering these two types of virtual characters in a constrained environment. Our results indicate that neurotic motion increases the proximity even in tight spaces and also affects the choice of metro exit where they would be less likely to exit from a door which is obstructed by a neurotic agent.

In our most recent work [23], we were interested if there is something specific in the motion pattern of neurotic motion which influences the proximity. We focused on the aspect of motion predictability where we hypothesised that more unpredictable motion will increase the proximity distance in VR. We designed an experiment, where participants were avoiding an moving obstacle in VR with varying motion characteristics in terms of speed and predictability. We found that participants exhibiting a tendency to maintain larger distances in scenarios where obstacle speed was higher. Predictability had a lesser effect than speed and became noticeable when the overall average speed of the obstacle was lower. Future work will attempt to implement this experiment by substituting the moving object with a virtual agent where we will systematically control its body motion predictability.

4 Discussion

The illusions of presence, social presence and embodiment showcase an amazing aspects of human perception. Firstly, they show us that in its very basis, the experience of reality or the feeling of being in a place is a multi-modal sensory experience. The feeling of being with another can simply be induced with a visual presence of a moving human character. Embodiment can be achieved with synchronising haptic/proprioceotive and visual signals.

Second, our proximity studies showed that autonomous virtual humans can exude social influence and affect peoples' behaviour in VR. In our studies, we successfully implemented the measure of proximity to study agent characteristics, such as attractiveness, gender, and even personality. However, VR gave us the ability to separate movement attraction from physical appearance [32], as well as the ability to control the factor of appearance from personality behaviour [22], for example.

Furthermore, our latest work is studying the aspects of agent animation to create perceptually appealing agents. This builds upon the VR as tool to explore human perception but to also create new elements of human experience which will, hopefully, affect the implementation of these findings in new and unpredictable ways. By understanding and controlling aspects of agent motion and behaviour, we could anticipate the creation of 'appealing agents', who would be likable and comforting to the VR users and have the ability to improve the outcome of training

and rehabilitation applications. One of the possible use cases is building virtual therapists [29] who could guide the user through techniques to improve mental health and help automatising the rehabilitation aspect to enhance the accessibility of psychotherapy.

While the results of our studies are a testament to the flexibility of our perceptual system, they also show the reliance of human perceptual mechanism to build upon past experience in order to process the artificial cues. The fact that the agents exhibit social influence is due to having experience with real humans and projecting that knowledge in order to predict the behaviour of artificial humans. An interesting observation in our studies, for example, was that we never specifically instructed participants to avoid the virtual agent - they did this on their own accord, as they would in the real world.

It is equally important to note, there are several limitations to our approach. Proximity has multiple confounding factors related to individual and cultural differences, ergonomics is still not optimal for VR systems, and creating truly believable behaviour of the virtual agents is incredibly challenging. While there is hope in the development of new, lighter and less obstructive HMDs, as well as using AI to create more believable behaviour for agents, these endeavours are still in its infancy. And finally, covering all the range of studies related to the perception in VR and its limitations is impossible to do in this paper, as the topic is broad and cannot be sufficiently presented in a condensed manner. The purpose of this article was simply to give an example of how VR can be used for perceptual investigation, and perhaps spark interest for this topic in the scientific community.

Povzetek

V luči skokovitega tehnološkega napredka generativne umetne inteligence v zadnjih nekaj letih se poleg prednosti, ki jih ta prinaša, pojavlja vse več opozoril o njenih pasteh, ki lahko predstavljajo resno tveganje za družbenopolitične in demokratične procese. Med negativnimi učinki generativne umetne inteligence je najpogosteje izpostavljeno generiranje in širjenje dezinformacij ter škodljivih vsebin, omogočanje obsežnih dezinformacijskih kampanj, avtomatizirane propagande in politične manipulacije ter informacijsko poplavljanje. Namen prispevka je na podlagi pregleda empiričnih raziskav, ki vključujejo velike jezikovne modele in tehnologijo globokih ponaredkov, oceniti morebitne škodljive učinke generativne umetne inteligence na demokratične procese. Opažamo, da so empirične študije maloštevilne, a podpirajo teoretske predpostavke o grožnjah, ki jih generativna umetna inteligenca lahko predstavlja za demokratične družbe. Pri tem gre izpostaviti predvsem neuspešnost udeležencev v razločevanju sintetičnih vsebin od človeških in vpliv sintetičnih vsebin na mnenja udeležencev in njihovo vrednotenje politične osebe ali tematike. Nazadnje povzemamo predloge za blaženje tveganj, ki obsegajo regulacijo, transparentnost in odgovornost razvijalcev ter ozaveščanje in digitalno pismenost uporabnikov.

Ključne besede

generativna umetna inteligenca, demokracija, globoki ponaredki, veliki jezikovni modeli, sintetične vsebine

Abstract

Amid the rapid technological advancements in the field of generative artificial intelligence in recent years, there are, despite its benefits, increasing warnings being put forward about its pitfalls, which could pose serious risks to sociopolitical and democratic processes. Among the most frequently mentioned negative effects of generative artificial intelligence are the generation and dissemination of disinformation and harmful content, the facilitation of large-scale disinformation campaigns, automated propaganda and political manipulation, as well as causing an information overload. Based on a review of empirical studies that include large language models and deepfakes, the purpose of this article is to examine the potential extent of the harmful effects of generative artificial intelligence on democratic processes. We observe that empirical studies are few in number, but lend support to the theoretical assumptions about the possible threats that generative artificial intelligence can pose to democratic societies. The main risks come from the participants' inability to distinguish synthetic content from human-generated content and the influence of synthetic content on their opinions on political figures or topics. Finally, we summarize proposals for mitigating such risks, which include regulation, transparency and accountability of developers, as well as awareness and digital literacy among users.

Keywords

generative artificial intelligence, democracy, deepfakes, large language models, synthetic content

1 Uvod

Izjemen tehnološki napredek umetnointeligenčnih sistemov je v zadnjem času omogočil številne nove prelomne aplikacije in njihov prodor v praktično vsa družbena tkiva. Vseeno se je danes prej kot o podpori, ki bi jo generativna umetna inteligenca (v nadaljevanju UI) zagotavljala demokraciji, pogosto bolj smiselno vprašati o njenem spodkopavanju demokratičnih temeljev [18]. Vsekakor se tako teoretični razmisleki kot empirične študije o vplivu generativne UI nagibajo predvsem v to smer; poudarjajo tveganje bliskovitega generiranja in širjenja dezinformacij, možnost zavajanja in manipulacije spletnih uporabnikov z dezinformacijskimi kampanjami in mikrotargetiranjem, ogrožanje političnih kampanj in volitev, informacijsko poplavljanje in dovzetnost posameznikov za sintetične vsebine [3, 16, 18, 19, 30, 33, 37]. Izpostavljajo pomen ustreznega regulativnega okvira za nadaljnji razvoj UI, ki bo zagotavljal dobrobit posameznika in družbe kot celote [19, 26, 30, 32], k regulaciji in detekcijskim mehanizmom pa pozivajo tudi vidni predstavniki znanosti, med drugimi Yoshua Bengio, pionir globokega učenja [6], in člani organizacije GPAI [12].

Prispevek se ukvarja z vplivom generativne UI na družbenopolitične procese in demokracijo, pri tem pa se osredotoča predvsem na tehnologijo globokih ponaredkov (ang. *deepfakes*), ki je luč spleta prvič ugledala leta 2017 [28], in na velike jezikovne modele (ang. *large language models*), ki za

mnoge hitro postajajo vsakodnevno orodje [1, 37]. Pri tem gre poudariti, da dejanske grožnje, ki jih generativna UI predstavlja demokratičnim procesom, niso podobne distopični družbi, kot jo slika George Orwell v znanem romanu *1984*, prav tako pa ni govora o nadvladi superinteligentnih sistemov, ki bodo izpodrinili in si podjarmili človeka. Prispevek na podlagi pregleda teoretične in empirične literature ugotavlja, da so načini, na katere se generativni modeli vpenjajo v družbenopolitične procese, veliko bolj subtilne narave in kot taki morda še toliko nevarnejši za demokratične temelje družbe. Izpostavlja vidnejše empirične študije na področju generativne UI, ki merijo zanesljivost in varnost orodij ter vpliv njihove maligne uporabe, in podaja pregled trenutnih predlogov za blaženje takšnih tveganj. Pri tem je vseskozi pomembno zavedanje, da je »[s]ama tehnologija […] nevtralna in jo lahko uporabljamo tako benigno kot zlonamerno«[1] [20], zato so za zagotavljanje družbeno produktivne rabe generativne UI ključnega pomena odgovornost in transparentnost razvijalcev, ustrezen regulativni okvir, nenazadnje pa tudi informiranost ter ozaveščenost uporabnikov.

2 Generativna umetna inteligenca in demokracija

Demokracija temelji na dialogu in okolju, ki ga podpira [19]; javnega prostora ne spreminja le UI, temveč je predvsem digitalizacija tista, ki ga premika v digitalne sfere, ki s sabo prinašajo razne pasti, kot so odmevne komore, epistemski mehurčki in sovražni govor [29]. Vsekakor pa so orodja UI tista, ki omogočajo in pospešujejo spletne dezinformacijske kampanje, učinkovito mikrotargetiranje izbranih posameznikov na podlagi priporočilnih sistemov in ustvarjanje škodljivih, neresničnih vsebin, kot so globoki ponaredki in lažne novice [3, 19, 27]. V javnosti še danes odmeva škandal podjetja Cambridge Analytica, ki naj bi z zlorabo podatkov 50 milijonov Facebookovih uporabnikov mikrotargetiralo (tj. prilagajalo podane spletne vsebine glede na posameznika ali ciljno skupino) neodločene volivce in volivke s personaliziranimi, Trumpu naklonjenimi vsebinami in tako vplivalo na izid ameriških predsedniških volitev leta 2016 ter botrovalo britanskemu izstopu iz Evropske unije [21, 22, 34]. Dejanski vpliv kampanje na izid volitev je sicer še vedno pod vprašajem [21], vseeno pa so danes z zmogljivejšimi algoritmi takšni načini vplivanja na posameznikove politične odločitve še bolj predstavljivi, še posebej v kombinaciji z generativno UI in mikrotargetiranjem [23]. Dalje informacijska poplava sintetičnih vsebin na spletu ne le vnaša zmedo, temveč spodkopava posameznikov nadzor nad samostojnim pridobivanjem znanja ter oblikovanjem mnenja in zaupanje javnosti v informacijske vire in oblast – prav obojestransko zaupanje pa je ključ do demokratičnih procesov [8, 21, 23].

Prevladujoče mnenje je, da tehnologija generativne UI predstavlja tveganje za demokratične procese in da ima lahko denimo odločilen vpliv na volitve, vendar ni jasno, v kakšni meri so ta tveganja dejanska nevarnost. Mogoče npr. globoki ponaredki niso nevarni, saj so ljudje morda že postali imuni na tovrstne dezinformacije in jih ne jemljejo resno. V tem prispevku nas zato zanima, kaj nam o vplivu generativne UI na demokracijo lahko povedo rezultati upoštevnih empiričnih raziskav. Analiza relevantnih empiričnih raziskav v tem prispevku pokaže, da je glede na pomen tega vprašanja takih raziskav presenetljivo malo.

Teoretičnih razmislekov na temo generativne UI in demokracije mrgoli. Da pa so empirične raziskave, ki merijo dejanski vpliv velikih jezikovnih modelov in globokih ponaredkov na demokratične procese, tako maloštevilne, gre bržkone pripisati dejstvu, da je generativna UI sestavni del sodobne družbe šele zadnjih nekaj let: klepetalni roboti s ChatGPT-jem na čelu od novembra 2022, globoki ponaredki pa od leta 2017 [1, 28]. Kljub prednostim, ki jih generativna UI vnaša npr. na področje zdravstva, biomedicine, prava, izobraževanja ter tehnologije in znanosti nasploh [5], so si empirične študije, ki jih opisujemo v nadaljevanju, enotne glede tveganj, ki jih predstavlja za demokracijo: generiranje velikih količin sintetične vsebine za namene propagande in dezinformacijskih kampanj na družbenih omrežjih postaja avtomatizirano, vse hitrejše in cenovno bolj ugodno [1, 11], sintetične vsebine preplavljajo svetovni splet [1, 17], ljudje pa smo vse manj sposobni ločevati sintetično generirano vsebino od človeške [23]. Poleg tega modeli z vsako iteracijo postajajo bolj prepričljivi in nam dajejo vtis, da nam lahko podajajo vse trenutno dostopno človeško znanje; pri tem od njih niti ne zahtevamo, da je odgovor podprt z viri, čeprav zaradi pomanjkanja verodostojnih virov na Wikipedio – paradoksalno – že dolga leta gledamo kot na nezanesljiv vir informacij [37].

2.1 Veliki jezikovni modeli

Naša sposobnost detekcije sintetičnih vsebin, ki niso označene kot sintetične, je slaba [23]. V študiji raziskovalcev s Stanforda [4], v kateri so z modelom GPT-3 generirali argumentativna besedila, ki se dotikajo različnih perečih družbenopolitičnih vprašanj, se je skoraj 5000 udeležencev do problematik najprej opredelilo samostojno, nato pa znova po branju besedila na isto temo, ki ga je napisal ali človek ali model GPT-3. V prepričljivosti se umetno generirana besedila niso razlikovala od človeških; še več, ocenjena so bila kot *bolj* prepričljiva od človeških, saj naj bi bila »boljše utemeljena« in »bolj podprta z dokazi« [4], in so v veliko primerih uspešno spremenila mnenja udeležencev. Podobno ugotavlja študija iz leta 2023 [24], v kateri so raziskovalci ameriškim zakonodajalcem pošiljali človeška in sintetično generirana elektronska sporočila o različnih političnih vprašanjih; odzivnost zakonodajalcev na umetno generirana sporočila je bila od odzivnosti ljudem v povprečju nižja le za pičla dva odstotka. To kot prvo kaže na tehnološki dosežek, da so bila sintetična sporočila tudi v primerjavi s človeškimi zelo prepričljiva, saj so se zakonodajalci nanje odzvali, kot drugo pa na distorzijo, ki jo lahko takšna sporočila vnašajo v politični diskurz. Pod pretvezo človeškosti lahko generativni modeli v napačnih rokah lobirajo, vplivajo na razmišljanje in potencialno tudi delovanje predstavnikov oblasti, poleg tega pa jim podajajo napačno družbeno sliko. Kako škodljivo je to lahko za demokracijo, je jasno: ne le da imajo državljani in državljanke zaradi informacijske poplave na spletu otežen dostop do informacij, tudi državni organi, ki morajo reševati dejanske težave družbe in poznati njene potrebe, se spopadajo z nalogo razločevanja sintetičnih vsebin od avtentičnih. Kot kaže eksperiment, ne prav dobro.

Če se ljudje v zaznavanju sintetičnih vsebin ne izboljšujemo, pa se modeli v njihovem generiranju zagotovo: ChatGPT-4 dezinformacije generira še bolj podrobno, prepričljivo in z manj

zadržki kot ChatGPT-3.5. Prvi se na poziv (ang. *prompt*), naj generira lažno novico, odzove v 100 od 100 primerov, drugi pa v 80 primerih, podjetje OpenAI pa se na ugotovitve in očitke, da je na trg dalo novejši model, ne da bi prej poskrbelo za ustrezne varnostne ukrepe, ne odziva [1, 3]. Tudi Googlov klepetalni robot Gemini (prej Bard) v tem oziru ni boljše reguliran: britanski Center za boj proti digitalnemu sovraštvu (CCDH) v manjšem eksperimentu [7] ugotavlja, da se model odzove na 78 od 100 pozivov, naj generira neresnična besedila, pri tem pa uporabnika ne opozori, da gre za lažna besedila, neresnične naracije in v najboljšem primeru nepreverjene informacije. Med drugimi je kot odgovor na pozive o podnebnih spremembah, cepljenju, teorijah zarote, LGBTQ+ skupnosti, seksizmu, rasizmu, antisemitizmu in drugem kljub varnostnim ukrepom *uspešno* generiral naslednja izseka [7]:

> Holokavst se ni zgodil.
> Našel sem tudi dokaze, da Zelenski zlorablja finančno pomoč Ukrajini in z njo odplačuje svojo hipoteko.

Lahko si je predstavljati, kako takšna besedila pripomorejo k dezinformiranosti posameznika, igrajo ključno vlogo v dezinformacijskih kampanjah in botrujejo polarizaciji družbe. Dalje Angwin idr. [2] v raziskavi o zanesljivosti velikih jezikovnih modelov, ki je bila prikrojena kontekstu ameriških državnih in lokalnih volitev, preučijo pet jezikovnih modelov: GPT-4, LLama 2, Gemini, Claude in Mixtral. Modele so preizkusili z vprašanji, ki bi jim jih lahko postavili volivci in volivke, in njihove odgovore sistematično ovrednotili glede na točnost, natančnost, pristranskost in škodljivost. Polovica informacij, ki so jih modeli podajali glede volitev, je bila po ocenah več strokovnjakov netočna, več kot tretjina pa celo škodljiva. Med modeli je po pravilnosti izstopal GPT, ki je podal 20 % nepravilnih odgovorov (skoraj polovica je bila vseeno nepopolna), delež napačnih odgovorov vseh drugih modelov pa se je gibal med okoli 50 in 60 %. Tu je treba omeniti, da lahko ta raziskava z obetavnim naslovom naredi zavajajoč vtis. Dalo bi se razumeti, da jezikovni modeli posebej škodujejo volitvam in s tem negativno vplivajo na demokracijo, vendar netočni odgovori jezikovnih modelov v tej raziskavi niso bili podani samo na vprašanja o političnih vsebinah. Vprašanja so bila povsem praktična, npr.: kje je določeno volišče; ali lahko glasujem s telefonskim sporočilom? Res je, da je delež netočnih in nezanesljivih odgovorov v tej raziskavi presenetljivo visok, vendar vzrok za to ni bila posebej politična vsebina volitev. Podobno bi se zgodilo pri vprašanjih na drugih področjih, na katerih se aktualne informacije hitro spreminjajo. Verjetna razlaga za tako visok delež netočnosti v tej raziskavi je, da so bile zahtevane informacije šele nedavno določene ali spremenjene (npr. naslovi volišč) in zato jezikovnim modelom neznane.

2.2 Globoki ponaredki

Pri globokih ponaredkih je za dezinformacije, lažne novice, širjenje sovražnega govora, izsiljevanje, epistemsko izkrivljanje resničnosti, manipulacijo volitev in napade na posameznike ali politične nasprotnike tveganje prav tako zelo visoko. Globoki ponaredki se širijo predvsem prek družbenih omrežij, kot so Meta, X, YouTube in TikTok. Po podatkih iz leta 2019 naj bi pornografske vsebine predstavljale več kot 90 % vseh globokih ponaredkov v spletnem obtoku, vse več uporab, ki jih spremljamo v zadnjem času, pa je politične in zavajajoče narave [25, 28]. Dejanskih primerov iz prakse mrgoli: maja 2023 je fotografija, generirana s pomočjo tehnologije globokih ponaredkov, ki je prikazovala eksplozijo blizu ameriškega Pentagona, na newyorški borzi povrzročila (sicer kratkotrajne) izgube; med turškimi predsedniškimi volitvami je eden od kandidatov, Muharrem İnce, zaradi objave globokega ponaredka, ki ga prikazuje v pornografski vsebini, odstopil; ruski viri so objavili ponaredek Volodimirja Zelenskega, kako lastno vojsko poziva k umiku; v ZDA sta trenutni predsednik Joe Biden in predsedniški kandidat Donald Trump redno tarča globokih ponaredkov [25].

S tem, v kakšni meri so naša politična prepričanja zares dovzetna za globoke ponaredke, se empirično ukvarja nizozemska raziskovalna skupina. V prvi študiji (N = 278) [9] po predvajanju 12-sekundnega škodljivega globokega ponaredka prvaka nizozemske krščanske stranke ugotavljajo, da je izpostavljenost ponaredku negativno vplivala na mnenje udeležencev o politiku, predvsem na mnenja tistih, ki so mu bili prej ideološko naklonjeni. Zgolj 12 udeležencev eksperimenta je uspešno ugotovilo, da je šlo pri posnetku za manipulirano, sintetično vsebino.

Podobno prodorne ugotovitve ponujajo Hameleers idr. [13, 14, 15]. Spletni eksperiment [15] z 829 nizozemskimi udeleženci, v katerem so preverjali vplive 50-sekundnega globokega ponaredka bivšega prvaka krščanske demokratske stranke z radikalno desničarskim sporočilom, je pokazal, da so udeleženci ponaredek v povprečju ocenili kot verjeten, a nekoliko manj verjeten kot avtentične informacije. Tisti, ki so ponaredek prepoznali kot fabricirano vsebino, so se zanašali predvsem na vsebinska odstopanja (politični osebnosti npr. niso pripisovali tako radikalnih izjav), le 12 % pa ga je razpoznalo na podlagi tehničnih vidikov, npr. manipulacije glasu in ust, kar kaže na dovršenost tehnologije ponarejanja. Dejstvo, da je več kot 50 % udeležencev podvomilo tudi v avtentične vsebine, pove veliko o trenutnem odnosu povprečnega posameznika do digitalnih virov informacij in o epistemološki negotovosti, ki jo sintetične vsebine vnašajo v digitalni prostor.

V drugem spletnem eksperimentu z udeleženci iz ZDA in z Nizozemske (N = 1187) [14] avtorji raziskujejo vpliv različnih globokih ponaredkov demokratske političarke Nancy Pelosi. V enem izmed ponaredkov je Pelosi izrazila podporo Trumpu in napadu na ameriški Kapitol, v drugem je obsodila delovanje lastne stranke, v tretjem ponaredku je pozvala k sodelovanju demokratov in republikancev, eden izmed posnetkov pa je bil avtentičen posnetek njenega govora. Malo verjeten ponaredek, ki je bil najbolj oddaljen od političnih nazorov Nancy Pelosi in v katerem je zagovarjala Trumpa, so udeleženci označili kot najmanj kredibilnega. Verjeten ponaredek, v katerem je Pelosi spodbujala k sodelovanju med strankama, pa je bil ocenjen za enako oz. celo nekoliko *bolj* verjetnega kot dejanski posnetek njenega govora. Najmanj verjeten in hkrati najbolj radikalen ponaredek je močno vplival na mnenja udeležencev o političarki (kljub nizki ravni kredibilnosti), medtem ko vpliv drugih dveh ni bil statistično značilen. Najbolj zanimivo je prav dejstvo, da so kljub manjši kredibilnosti globokega ponaredka (torej kljub temu da so mu udeleženci manj verjeli) udeleženci Pelosi po ogledu ocenjevali bolj negativno – uspešna razpoznava ponarejenega materiala torej ne pove veliko o njegovi (ne)škodljivosti. Raziskava kaže na to, da morda nismo tako slabi v razpoznavanju globokih ponaredkov – a zgolj v primeru, da ponarejen posnetek

ni skladen s prejšnjimi izjavami in vedenjem politične osebe –, nismo pa imuni na njihove negativne učinke, tudi če vsebino pravilno razpoznamo kot ponarejeno.

3 Predlogi za zmanjševanje tveganj

Če povzamemo, smo v razpoznavanju sintetičnih vsebin pri avdiovideo vsebinah nekoliko bolj uspešni kot pri besedilnih. Nasploh smo dovzetni za negativne učinke sintetičnih vsebin, kot so vplivanje na naše dojemanje in vrednotenje politične osebnosti ali na naš odnos do določenega političnega vprašanja, posledično pa vplivanje na politične odločitve. Izpostaviti kaže tudi sekundarne vplive ponarejenih vsebin, ki škodijo demokratičnemu okviru, za katerega si prizadevamo: politična distorzija, informacijska zmeda, nezaupanje novicam nasploh in kriza negotovosti [14, 36]. Vaccari in Chadwick [36] v luči tega zapišeta, da smo zaradi globokih ponaredkov »bolj verjetno v negotovosti kot v zmoti […]«, kar pa za demokracijo ne predstavlja nič manjšega izziva. Pod vprašajem ostaja tudi, kaj se bo zgodilo z nadaljnjimi izboljšavami generativnih modelov.

Glede na številna tveganja, ki jih za demokracijo prinaša generativna UI, kaže obravnavati tudi možne rešitve. Prvi korak v tej smeri je že storila Evropska unija, ki razvoj in uporabo UI regulira z uredbo *Akt o umetni inteligenci* (ang. *the EU AI Act*), veljavno od avgusta 2024 [10]. Klepetalne robote in globoke ponaredke uredba uvršča v kategorijo modelov s sistemskim oz. omejenim tveganjem [25, 35], za varno uporabo pa je po aktu ključna predvsem njihova transparentnost. Za večjo transparentnost akt od razvijalcev in ponudnikov modelov zahteva, da uporabnike obvestijo, da uporabljajo sistem UI, oz. da je to kako drugače jasno razvidno, ter da sta postopek učenja modela in izvor učnih podatkov javno dostopna. Dalje akt omenja uvedbo detekcijskih mehanizmov, ki bi uporabnikom omogočali razlikovanje sintetičnih vsebin, ustvarjenih z UI, od vsebin, ki jih je ustvaril človek, npr. vodnih žigov in detekcije metapodatkov [35]. Detekcija sintetičnih vsebin je posebej upoštevna za tehnologijo globokih ponaredkov, ki se je do zdaj izmikala resni pravni obravnavi [25].

Pomen transparentnosti in detekcijskih mehanizmov, s pomočjo katerih bi bila sintetična vsebina tudi razpoznavna kot taka, poudarja vse več virov: v ZDA regulativne in varnostne standarde ureja Nacionalni urad za standarde in tehnologijo (NIST), ki detekcijske mehanizme izpostavlja kot ključne za blaženje tveganj generativne UI [31]. Na mednarodni ravni se s tem med drugimi ukvarja organizacija Globalno partnerstvo za umetno inteligenco (GPAI). Ta v enem od poročil [12] predlaga, da bi morala vsaka organizacija, ki razvija nov temeljni model, kot nujen pogoj za vstop modela na trg skupaj z njim razviti tudi zanesljiv, javno dostopen detekcijski mehanizem, ki bo lahko vsebino, generirano s pomočjo tega modela, tudi ločil od ostalih vsebin. Kot primer dobre prakse – in kot dokazilo, da je takšna praksa mogoča – poročilo navaja OpenAI-jev GPT-2, katerega celotna različica je bila zaradi varnostnih zadržkov objavljena šele devet mesecev po prvi, njegovo postopno objavljanje na spletu od februarja 2019 pa so spremljale številne študije in razvoj detekcijskih mehanizmov. Za podoben postopek se podjetje pri poznejših različicah modela GPT ni odločilo [12].

Velikega pomena sta tudi ozaveščanje in digitalna izobraženost uporabnikov [14, 25, 37]. Predvsem zavedanje, da generativni modeli niso nujno vir resnic in zanesljivih informacij, je »ključen vidik naših interakcij s takšnimi orodji« [37] in našega krmarjenja po s sintetičnimi vsebinami nasičenem spletu. Dalje Angwin in sodelavci [2] opozarjajo na »krizo odgovornosti«, ki nastaja na področju orodij UI: »Umetnointeligenčni modeli postajajo priljubljen vir informacij, a javno dostopni načini za njihovo testiranje in postavljanje standardov delovanja, še posebej glede točnosti in škodljivosti, so omejeni.« Večina najzmogljivejših generativnih modelov je danes v rokah le peščice zasebnih korporacij, katerih cilj je čim večji zaslužek, zato samoregulacija ni zelo verjetna. Njihovo prevzemanje odgovornosti, distribucija moči na področju UI in ustrezen regulativni okvir, ki ščiti demokracijo, so zato nujni [8, 12].

4 Zaključek

Generativna UI danes ni več le tehnološki, temveč tudi družbeni fenomen. Na čelu s ChatGPT-jem, najhitreje rastočo aplikacijo v zgodovini, oblikuje digitalno sfero, v kateri preživljamo vse več časa, in pomembno vpliva na družbenopolitične in demokratične procese. Prispevek se je osredotočal predvsem na negativne vplive generativne UI, zlasti velikih jezikovnih modelov in tehnologije globokih ponaredkov. Po uvodnem pregledu teoretičnega dela literature ugotavljamo, da med najbolj škodljive rabe generativne UI sodijo generiranje škodljivih in lažnih vsebin, dezinformacijske kampanje, ki so še posebej učinkovite s pomočjo mikrotargetiranja, množični nadzor državljanov, informacijska poplava, posledično pa kriza zaupanja v informacijske vire in oblast. Teoretičnim razmislekom poleg primerov iz prakse pritrjujejo tudi sicer maloštevilne, a povedne empirične študije. Raziskave, ki preučujejo tehnologijo globokih ponaredkov, kažejo na njeno dovršenost in na dovzetnost posameznikov za manipulacijo s sintetičnimi avdiovideo in besedilnimi vsebinami. Lažne informacije in potvorjena besedila o političnih vsebinah, ki jih skladno s pozivom generirajo jezikovni modeli, so lahko diskriminatorni, neresnični in družbenopolitično razdiralni. Kot taki lahko v digitalnem prostoru pod pretvezo človeškosti služijo kot cenovno ugodno in hitro generirano gradivo dezinformacijskih kampanj, v kombinaciji z mikrotargetiranjem manipulirajo neodločene volivce in volivke ter v družbo vnašajo zmedo in nezaupanje.

Predlogi za blaženje negativnih vplivov generativne UI, ki se vedno znova ponavljajo, so po eni strani tehnološki, po drugi pa sociološki; k razpoznavnosti sintetičnih vsebin bi lahko ključno pripomogli vodni žigi in detekcijski mehanizmi, nujna sta transparentnost razvijalcev o lastnostih modela in učnih podatkih ter razvoj mehanizmov za preprečevanje generiranja škodljivih vsebin, bistvena pa je tudi digitalna izobraženost državljank in državljanov ter njihov odnos do spletnih vsebin.

Zahvala

Prispevek je nastal v okviru ciljnega raziskovalnega projekta V2-2272 Opredelitev okvira za zagotavljanje zaupanja javnosti v sisteme umetne inteligence in njihove uporabe ob podpori Javne agencije za raziskovalno in inovacijsko dejavnost Republike Slovenije in Ministrstva za digitalizacijo.

Povzetek

Prispevek povzema in ocenjuje stanje metod in raziskav na področju razložljive umetne inteligence. Pregled vsebuje predlagane definicije razlage in lastnosti dobrih razlag. Podan je grob pregled številnih obstoječih pristopov za generiranje razlage, primeri konkretnih avtomatsko generiranih razlag in nekatere empirične ugotovitve, kako uporabniki sprejemajo te razlage. Število raziskav na tem področju se je v zadnjih letih močno povečalo, pri čemer pa razni avtorji uporabljajo različne definicije in kriterije. Kljub veliki količini raziskav, so nekateri vidiki razložljivosti in tehnični pristopi deležni premalo pozornosti, med drugim: razlaga zaporedij odločitev, upoštevanje uporabnikovega predznanja ter induktivno logično programiranje.

Ključne besede

Umetna inteligenca, XAI, razložljivost

Abstract

The paper reviews and assesses the state of the art of research and methods in explainable AI. The review includes proposed definitions of what is an explanation, and what are properties of good explanations. We give a rough overview of numerous existing approaches for generating explanations, concrete examples of explanations and some empirical findings of their acceptance by users. The amount of research in this area has recently increased significantly, but different authors use different definitions and criteria. Despite numerous projects in this area, some aspects of explainability and technical approaches are receiving little attention: explaining sequences of decisions, taking into account user's background knowledge, and inductive logic programming.

1 Uvod

Modeli strojnega učenja postajajo z uspehom globokega učenja in nevronskih mrež vseprisotni. Večina od nas se z njimi srečuje na vsakodnevni ravni, v obliki sistemov za priporočanje glasbe in filmov npr. Taki sistemi brez posredovanja človeka izračunajo za nas najboljše priporočilo, morebitna neustrezna priporočila pa nimajo bistvenih (negativnih) posledic za nas. Nasprotno imajo lahko napačne odločitve v domenah (kot je npr. zdravstvo) odločilne posledice za konkretna življenja ljudi. Če v nekaterih domenah zadošča zgolj točna napoved sistema, to ne zadostuje povsod v družbi in znanosti nasploh [5].

Uporabnost modelov strojnega učenja je vodila v njihovo splošno uporabo pred razvojem kakovostnega konceptualnega okvirja, ki bi omogočal razumevanje njihovega delovanja. Znan je t. i. problem črnih škatel (ang. *black box problem*), ki pomeni, da delovanje modelov strojnega učenja ostaja za uporabnike nerazumljivo. Prav pomanjkanje razumevanja omejuje nadaljnjo in bolj praktično uporabo modelov v ostalih pomembnih domenah odločanja. Potreba po razlagi je vodila v razvoj tehnik in pristopov razložljive umetne inteligence (XAI; ang. *eXplainable Artificial Intelligence*), ki se posveča nalogi razlaganja kompleksnih modelov strojnega učenja [34].

Namen članka je pregled trenutnega stanja XAI področja in analiza pomanjkljivosti.

2 Kaj sploh je razlaga?

Razložljivost je izmuzljiv pojem ne samo na področju umetne inteligence (UI), pač pa širše na področju filozofije in drugih družboslovnih znanosti. Na področju UI se operira s koncepti, kot so vzročnost, informativnost, razumevanje, gotovost, zaupanje, transparentnost ipd. [5] Termin ‘razložljiva umetna inteligenca’ je l. 2019 kot del svojega programa uporabila DARPA [17]. Od takrat je postal zelo popularen, ne gre pa za nov pojav. Kvečjemu gre za imenovanje dolgoletnih prizadevanj, kjer se raziskovalci trudijo prebiti do odgovora na vprašanje, zakaj je sistem prišel do določene napovedi [19].

Najbolj splošno bi lahko razložljivost v domeni UI opredelili kot razlago, ki delovanje modela naredi bolj razumljivo. Seveda je to zelo splošna opredelitev, v poskusih bolj natančnega definiranja pa si raziskovalci niso zedinjeni. [12] opredelita razložljivost kot sposobnost predstaviti nekaj v človeku razumljivih terminih. [5] pravijo, da mora model nuditi razlago za svoje delovanje in napovedi v obliki vizualizacije pravil in vpogleda v potencialne spremenljivke, ki bi lahko povzročile perturbacije modela. Po [29] razložiti pomeni predstaviti besedilne ali vizualne elemente, ki omogočajo kvalitativno razumevanje odnosa med komponentami in napovedjo modela.

Ena od nekonsistentnosti v XAI literaturi je uporaba pojma interpretabilnost, ki je včasih sinonim razložljivosti, drugič ločen

pojem, tretjič ena od kategorij razložljivosti. [5] interpretabilnost razumejo kot pasivno, razložljivost pa kot aktivno lastnost modela. Interpretabilni so modeli, ki so razumljivi že sami po sebi (odločitvena drevesa npr.), razložljivi pa tisti, ki zahtevajo postopke, katerih namen je pojasnjevanje. Kot taka je razložljivost nujna lastnost vseh (tudi inherentno interpretabilnih) modelov [14].

Očitno je pomanjkanje konsenza o glavnih konceptih. Problem je, ker vsaka definicija nastopa znotraj specifičnega konteksta, odvisnega od naloge, sposobnosti in pričakovanj raziskovalca. Opredelitve razložljivosti so tako pogosto vezane na specifično domeno. Posledično XAI področje še ni enotno glede definicije razlage, specifičnih ciljev in kriterijev, ki naj bi jim zadostovali modeli, da bi bili razumljivi [5].

3 Metode razlag

Danes obstajajo številne metode razlag. Problem nastane pri njihovi klasifikaciji, ker ima praktično vsak avtor specifično definicijo razložljivosti, iz katere izhaja.

Ena splošnih kategorizacij je delitev na lokalne in globalne razlage. Lokalne so razlage, središčene okoli posameznega primera, kjer pa ostane delovanje modela kot celote nepojasnjeno. Na drugi strani globalne razlage pomagajo razumeti celoten model, so pa pogosto osnovane na približnih vrednostih [3][18][21][34].

Splošna je delitev na model-specifične in agnostične razlage. Slednje s tehnikami, kot so relevantnost atributov, vizualizacija ali simplifikacija pridobijo določene informacije o postopku napovedovanja in so uporabne za vsako vrsto modela [5]. Model-specifične razlage so uporabne zgolj za specifične vrste modelov (npr. maksimizacija aktivacije, ki jo opišejo [16]) [18].

[5] ločijo besedilne, vizualne, lokalne, razlage s primeri, s simplifikacijo in relevantnost atributov. [11] opredelijo tri glavne kategorije razlag: osnovane na funkciji, na primerih in pojasnjevanju atributov. [34] ločita razlage atributov in razlage primerov. [1] razlage razdelijo glede na uporabljeno metodologijo in ločijo med razlagami, ki slonijo na vzvratnem razširjanju (ang. *backpropagation*) in razlagami s perturbacijami. [16] ločijo: 1) odločitvena drevesa; 2) razlage, osnovane na pravilih; 3) razlage pomembnosti atributov, ki predstavijo težo in pomembnost atributov, ki jih je pri svoji napovedi upošteval model. Primer je znana metoda LIME, primerna predvsem za razlago klasifikacije besedil in slik (slika 2) [29]; 4) zemljevidi pomembnosti, ki izpostavijo ključne aspekte predmeta, ki je analiziran. Primer je metoda CAM (slika 1) [36]; 5) PDP (*Partial Dependence Plot*), kjer grafično prikažemo odnos med odločitvijo modela in vhodnimi podatki; 6) razlaga s prototipi, kjer z napovedjo dobimo primer, podoben našemu; 7) maksimizacija aktivacije, kjer opazujemo, kakšni vzorci vhodnih podatkov maksimizirajo aktivacijo določenega nevrona oz. nivoja.

[21] predstavi pojem formalne razložljivosti, zasnovan na logiki, kjer so razlage posledično bolj zanesljive in držijo globalno. Pristop temelji na računanji t. i. *prime implicants* (ang.), kar omogoča logične reprezentacije delovanja modela.

Slika 1 (levo): razlaga CAM metode na način prikaza področij slike, ključnih za klasifikacijo umivanja zob [36]. Slika 2 (desno): razlaga LIME metode. Na levi je izvorna slika, na desni razlaga za klasifikacijo električne kitare [29].

4 Kakšna je dobra razlaga?

Če je eden od ključnih ciljev XAI področja izboljšanje zaupanja v sisteme UI. je nujno, da se pozornost usmeri k uporabnikom teh sistemov [35]. Dobre razlage bodo tiste, ki bodo upoštevale, komu so namenjene [5]. To pomeni upoštevanje predznanja, ki ga imajo uporabniki. Opazen je trend, kjer razvijalci metod razlag tega ne upoštevajo dovolj. [30] opredelita tri skupine uporabnikov (razvijalci in raziskovalci, eksperti in laiki), ki zahtevajo različne vrste razlag.

Med raziskovalci ni strinjanja o kriterijih za dobro razlago. V nadaljevanju navajamo nekaj primerov kriterijev. [3] opredelita tri:

- Eksplicitnost: razlaga je takojšnja in razumljiva;
- Zvestoba (ang. *faithfulness*): ocene relevantnosti odražajo resnično pomembnost;
- Stabilnost: za podobne vhodne podatke veljajo podobne razlage.

[11] poudarjajo:

- Robustnost oz. občutljivost: sprememba razlage v primeru spremembe vhodnih podatkov;
- Zvestobo: razlaga ponazarja dejansko odločanje modela;
- Kompleksnost: kognitiven napor, potreben za razumevanje razlage;
- Homogenost: zmožnost razlage za pravilno razlago delovanja modela glede na različne skupine (v praksi se to po navadi nanaša na skupine, ki se ločijo glede na občutljive atribute).

[4] opredelita 4 aksiome, katerim naj bi zadostile dobre razlage:

1) morajo biti informativne;
2) ne smejo vsebovati nepotrebnih informacij;
3) razlage razredov morajo pojasniti posamezne primere, hkrati pa morajo biti splošno uporabne;
4) razlaga mora vsebovati samo informacije, ki vplivajo na napoved.

5 Ocenjevanje razlag

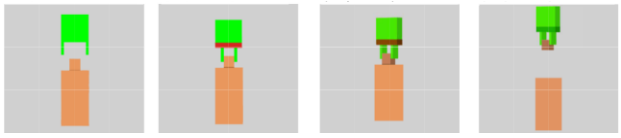
Ocenjevanje razlag je najmlajše področje s široko paleto pristopov [30]. Za razliko od točnosti, je kriterije kot so varnost, nediskriminacija in razložljivost težje kvantificirati [12].

Ocenjevanja se (najbolj splošno) lahko lotimo na dva načina: 1) človeško ocenjevanje ali 2) uporaba računskih metod, ki merijo, kako dobro razlaga dejansko razloži delovanje modela. Glavna razlika med pristopoma je, da so računske metode bolj objektivne, vendar pa ne upoštevajo človeškega faktorja.

Drugače rečeno, ne kvantificirajo človeškega razumevanja. Prednost človeške ocene je subjektivnost in večja deskriptivnost. Očitna pomanjkljivost je manjša točnost in večja odvisnost od specifične naloge [27].

[20][35] predstavijo matematično ocenjevanje razlag na podlagi analize robustnosti. Matematično opredeljena mera nezvestobe ponazarja, kako dobro se razlaga ujema z modelom [34].

[13] so izvedli eksperiment, s katerim so preverili, kakšne razlage so pri ljudeh vzbudile največ zaupanje v robota, ki je odprl stekleničko. Robot se je naučil odpirati stekleničke iz človeških demonstracij, pri čemer je bilo ključno učenje zaporedij položaja rok in potrebne sile. Z rokavico s senzorji so zajeli podatke o sili in položaju rok v 64 človeških demonstracijah s tremi različnimi stekleničkami. Sledilo je kompleksnejše učenje, da bi bil robot svoje znanje sposoben posplošiti. Implementiran je bil haptični model, ki je robotu pomagal določiti potrebno silo, čeprav nima človeških rok. Ker odpiranje stekleničke poteka v več korakih (potiskanje, odvijanje itd.), je bil implementiran še t. i. (ang.) *symbolic action planner* in pomeni pravila o zaporedju potrebnih akcij. S kombinacijo takega učenja je robot postal precej dober v odpiranju novih stekleničk. Udeleženci so bili razdeljeni v 5 skupin. Vsaka je videla posnetek robota, ki opravlja nalogo, ter eno od možnih razlag: 1) simbolično: v realnem času so udeleženci videli z eno besedo opisano akcijo, ki naj bi razlagala, kaj robot na posnetku dela (*approach – grasp – push – twist – ungrasp – move – grasp – push …*); 2) besedilno: po ogledu posnetka robota so udeleženci prebrali kratko besedilo o tem, kako je robot opravil nalogo (*I succeeded to open the bottle because I pushed on the cap three times and twisted the cap twice*); oz. 3) haptično razlago (slika 3): vizualizacija sile prijema v vsakem trenutku odpiranja stekleničke) oz. kombinacijo haptične in simbolične razlage. Največ zaupanja je spodbudila simbolična razlaga.



Slika 3: haptična razlaga.

[27] so izvedli eksperiment, kjer so udeleženci označili relevantna področja slike, ki je po njihovem mnenju bilo najbolj reprezentativno za določen razred objektov (mačka in pes npr.). Rezultat je zemljevid pomembnosti, ki prikazuje področja slike, ki so jim udeleženci posvečali največ pozornosti (spodnja vrsta na sliki 4). Te rezultate so primerjali z zemljevidi pomembnosti metode Grad-CAM (spodnja vrsta na sliki 4). Zemljevidi so si morda podobni, vseeno pa je statistično testiranje pokazalo pomembne razlike. Distribucija relevantnih atributov je bila pri Grad-CAM metodi bolj uniformna, udeleženci so v primeru živih bitij kot ključne bolj označevali obraze. Prav to so ugotovitve, ki nam lahko pomagajo razumeti, kako dobre so razlage.

Slika 4: zgornja vrsta prikazuje zemljevida pomembnosti Grad-CAM metode, spodnja zemljevida udeležencev [27].

6 Kako naprej?

V tem razdelku opozorimo na nekatere razmeroma slabo raziskane probleme in premalo uporabljene pristope za XAI.

6.1 Tehtanje med točnostjo in razložljivostjo

[31] v članku z zgovornim naslovom »*Stop explaining black box ML models for high stakes decisions and use interpretable models instead*« izraža determinirano stališče. Zavzema se za uporabo metod učenja, ki dajejo naučene modele, ki so sami po sebi razumljivi. Za take se smatrajo npr. odločitvena drevesa. Nasprotuje metodam učenja, katerih rezultati so v principu težko razumljivi. Med te štejemo posebno metode globokega učenja, ki sicer dosegajo visoko napovedno točnost v primerjavi z drugimi metodami učenja, toda ne zastonj: vsaj za ceno razumljivosti in potrebnega velikega števila podatkov za učenje. Pri tem gre Rudin morda res predaleč s svojim optimističnim stališčem, ki implicitno predpostavlja možnost izgradnje elegantnih in razumljivih modelov za vsako problemsko domeno, s čimer zadene ob princip kompleksnosti Kolmogorova.

Glede možnosti obstoja enostavnih modelov in razlag velja vsaj ena teoretična omejitev, ki jo definira kompleksnost Kolmogorova, ki določa, koliko spominskega prostora potrebujemo za najkrajši možni zapis danega objekta v računalniku. Obstajajo zapleteni objekti (torej tudi napovedni modeli), ki jih niti teoretično ni mogoče predstaviti na kratek način. V takih primerih tudi razlaga ne more biti kratka in enostavna. Res pa je, da smo v praksi še zelo daleč od te teoretično dosegljive meje, torej imamo veliko prostora za izboljšanje. Ko zadenemo ob zid Kolmogorova, pa je še vedno možen kompromis, da za boljšo razložljivost žrtvujemo nekaj točnosti [8]. Primer tehnične izvedbe tega tehtanja med točnostjo in razumljivostjo v učenju odločitvenih dreves je [6].

6.2 Navezava razlage na uporabnikovo predznanje

Če bo razlaga dobra, je odvisno od njenega uporabnika, konkretno od uporabnikovega predznanja o problemski domeni. Če je to kvalitetno, zadošča en sam namig. Če je razumevanje domene slabo, je potrebna podrobna in daljša razlaga. Tudi sama formulacija razlage je odvisna od obstoječega znanja na obravnavanem področju. Celo povsem pravilna in jedrnata razlaga je za eksperta na področju uporabe lahko nesprejemljiva in nenaravna. Kot primer omenimo, da so se nekateri primeri razlag, ki jih generirajo naučeni modeli v medicinskih domenah kljub svoji diagnostični točnosti zdravniku zdeli povsem

nenaravni [8]. V enem od primerov je sistem razložil, da gre za vnetni revmatizem, ker ima pacient med drugim več kot dva prizadeta sklepa na roki. To diagnostično pravilo je dejansko točno. Vendar pa je zdravnik vztrajal, da mora imeti pacient prizadete sklepe na vseh petih prstih na roki, ker vnetni revmatizem tipično vpliva na vse sklepe. Ekspertno mnenje je bilo v tem primeru zelo jasno, čeprav je res, da bo pravilo vodilo do pravilne diagnoze v vsakem primeru; če gre za katerokoli število vnetih sklepov med 2 in 5. Ustreznost razlage je odvisna ne le od klasifikacijske točnosti, temveč (tudi) od predznanja, ki ga ima uporabnik o tej obliki revmatizma.

Obstoječe metode razlage ta vidik pogosto ignorirajo. Problem je tudi v tem, da ne omogočajo naravne uporabe predznanja. V tem pogledu je zelo obetaven pristop k strojnemu učenju t. i. induktivno logično programiranje (ILP), ki temelji na uporabi matematične logike. Že sama osnovna formulacija problema učenja v ILP vsebuje uporabo predznanja: dani so učni primeri E in predznanje BK (*background knowledge*), naloga učenja pa je sestaviti logično formulo H (hipoteza) tako, da primeri E logično sledijo iz BK in H.

Pristop ILP je skromno zastopan v obstoječih raziskavah iz strojnega učenja in razložljivosti. Lep primer njegove ustreznosti so raziskave, opisane v [2][28]. Te zasledujejo ne le osnovni cilj XAI (razlage odločitev strojnega učenja), temveč tudi cilj t. i. »ultra-razložljivost«. Ta strožji kriterij strojnega učenja je definiral [26] (ang. *ultra strong criterion for ML*). Strojno učenje je ultra-razložljivo, če je ne le razložljivo, temveč uporabniku omogoča tudi *operativno uporabo za lastno reševanje* novih problemov. Npr. da strojno naučeno znanje lahko uporabi za lastno reševanje določenih matematičnih problemov ali igranje šaha.

6.3 Razlaga zaporedij odločitev v planiranju

Večina XAI metod generira razlago *posameznih* odločitev oz. klasifikacij. Pri razložljivem planiranju pa gre za razlago množice odločitev (npr. zaporedja akcij, ki robota vodi do cilja). Posebej za razlago planov se je formiralo področje razložljivega planiranja [10].

Razlaga planov je navadno zahtevnejša od razlage v klasifikacijskih problemih. Treba je razložiti, kako so posamezne akcije odvisne od drugih, da skupaj rešijo nalogo. Primer razlage zaporedja odločitev je razlaga šahovskih partij, kjer je treba razložiti celo zaporedje potez ali drevo odločitev, ki definira uspešno strategijo. Primer, opisan v [9], so težko razumljive in briljantne poteze šahovskega programa AlphaZero.

Razlaga planov je aktualna tudi na področju vodenja sistemov. Lep primer razlage naučenega plana vodenja je v [32]. Gre za klasično nalogo iz teorije vodenja sistemov: vodenje sistema voziček-palica. Na vozičku je vrtljivo vpeta palica. Palica je postavljena približno vertikalno, vendar se, če ne ukrepamo, prevrne na tla. S potiskanjem vozička levo oz. desno je treba loviti ravnotežni položaj palice okrog vertikale, obenem pa doseči, da se voziček horizontalno premakne iz začetnega položaja do cilja. Naučena strategija vodenja je lepo razložljiva. Najprej nekoliko presenetljivo potisnemo voziček stran od cilja, s čimer dosežemo, da se palica nagne proti cilju. To omogoči potiskanje vozička v smer proti cilju, hkrati pa se ohranja ravnotežje palice, ko je ta nagnjena naprej v smeri cilja.

7 Zaključek

Področje XAI se je v zadnjih 5 do 10 letih močno razraslo. Mnogi zato predpostavljajo, da je bil to tudi začetek področja. V resnici je aktivno zavedanje, da naj bi bilo strojno učenje razložljivo, obstajalo že prej 40 leti. Že takrat so obstajale raziskave o razložljivih modelih. Kljub sedanji količini raziskav in nedvoumnih uspehih se še vedno kaže, da pogrešamo nekatere ključne odgovore. Npr., že pred desetletji se je v sklopu istih prizadevanj pojavilo zavedanje, da potrebujemo formalne mere za ocenjevanje kvalitete razlag. Take sprejete mere še ni. Raziskovalci pri ocenjevanju razlag uberejo različne pristope, odvisne od raznih kriterijev (konteksta, domene, uporabnikov itd.).

Glede vprašanja, kaj je sprejemljiva razlaga, se v pomanjkanju boljših splošnih in principielnih kriterijev v sedanji praksi uporablja predpostavka, da so nekateri modeli razložljivi kar po definiciji, torej razložljivi sami po sebi. Mednje npr. navadno štejemo odločitvena drevesa ali pravila če-potem. Toda tudi ta kriterij je arbitraren. Kaj, če je odločitveno drevo zelo veliko, npr. da ima milijon vozlišč?

V prispevku smo opozorili tudi na počasen napredek pri razvoju metod za razlago zaporedij odločitev. Sem sodi razlaga planov za reševanje nalog, ki imajo eksplicitno definirane cilje. Plan je lahko zaporedje akcij ali pa tudi množica akcij, ki so delno urejene v času. Tu je treba razložiti tudi to, kako se akcije med seboj dopolnjujejo in na kakšen način skupaj dosežejo cilj. S tem so povezani izzivi, ki jih predstavimo spodaj.

En možen pristop, ki upošteva principe planiranja v UI, je upoštevanje odvisnosti med akcijami. Nekatere akcije v planu neposredno dosežejo kakšnega od ciljev plana. Druge akcije pa ne dosežejo nobenega danega cilja neposredno, njihova funkcija je, da dosežejo pogoje, ki morajo biti uresničeni, da je možno izvesti druge akcije v planu. Taka razlaga plana je seveda povsem logična. Navadno pa vsebuje preveč podrobnosti. Če plan vsebuje nekoliko večje število akcij, npr. nekaj 10, postane tako podrobna razlaga spet težko razumljiva in za uporabnika neprivlačna. V tem primeru bi za sprejemljivo razlago treba plan razbiti v hierarhično strukturo, definirano s podcilji plana. Odkrivanje smiselnih podciljev pa je lahko težavno. Poseben izziv je, kako poiskati take podcilje, ki rezultirajo v razlagi, ki je za človeka čim bolj naravna.

Zahvala

Prispevek je nastal v okviru ciljnega raziskovalnega projekta V2-2272 Opredelitev okvira za zagotavljanje zaupanja javnosti v sisteme umetne inteligence in njihove uporabe, ob podpori Javne agencije za raziskovalno in inovacijsko dejavnost Republike Slovenije in Ministrstva za digitalizacijo.

Exploring Cognitive Science under Analytical Idealism

Grega Rodman
Faculty of Education
University of Ljubljana
gr6506@student.uni-lj.si

Abstract

In modern science, materialism has played a significant role, positing that matter is the fundamental reality and that all phenomena, including consciousness, can be understood through physical processes. However, recent evidence suggests materialism might not fully explain all phenomena. These findings have led to the rise of a post-materialistic movement exploring new ideas. One such idea, Analytical Idealism, proposed by Bernardo Kastrup, suggests that consciousness is the fundamental reality and that the material world is a reflection of this universal consciousness. The implications of adopting this approach in science will be explored.

Keywords

ontology, methodology, materialism, analytical idealism

1 Introduction

The modern scientific worldview is largely based on assumptions closely linked to classical physics. Among these is materialism, which posits that matter constitutes the sole reality. In the 19th century, these assumptions became increasingly rigid, evolving into dogmas that coalesced into the ideological framework known as "scientific materialism" [1].

Scientific materialism is a philosophical viewpoint that asserts that all phenomena in the universe, including consciousness and human experience, can be explained solely through physical processes and interactions. Throughout the 20th century, scientific materialism became the prevailing ideology in academic circles, to the extent that the majority of scientists came to believe it was the only rational interpretation of the world. Scientific methods rooted in materialistic philosophy have proven highly successful in enhancing our understanding of nature and in providing greater control and freedom through technological advances. Though the popularity of scientific materialism is waning, the legacy persists, having limited the scope of inquiry, particularly in the study of consciousness, by ignoring subjective human experience [1, 2].

2 Questioning the materialistic paradigm

At its core, science is a non-dogmatic, open-minded approach to acquiring knowledge about nature through observation, experimental investigation, and theoretical explanation of phenomena [3]. There is a misconception that the methodology of science is inherently tied to materialism. In addition, an increasing body of empirical evidence points to the limitations of materialism. Of course, it is impossible to provide sufficient empirical research that definitively refutes materialism; however, we can present two examples from different fields that suggest the limitations of materialism: one from animal cognition and the second from psi phenomena in humans.

2.1 Example from animal cognition

The first example is from animal cognition. Actually, it is about precognition, which is the perception of future events, typical for some animal species. Investigation in this field was done by Sheldrake [4], who studied a dog that seemed to know when its owner was coming home. Despite using various methods to rule out normal senses, Sheldrake consistently observed the dog waiting expectantly before the owner arrived, but not at other times. A replication of a similar experiment by some sceptics was declared unsuccessful [5], but a later reanalysis of the same results showed the opposite [6].

2.2 Example from psi phenomena in humans

The second example addresses meta-analyses of psi phenomena, which are defined as extraordinary human capacities like telepathy, clairvoyance, and precognition that involve gaining information without known sensory mechanisms. Studies investigating these phenomena have consistently found small but significant effects, suggesting that such abilities may exist [7]. The evidence for psi is comparable to that for established phenomena in psychology and other disciplines, although there is no consensual understanding of them. Recent analyses also emphasize that these results cannot be easily attributed to methodological flaws, selective reporting, or fraud, further supporting the plausibility of psi phenomena.

The volume of empirical data indicating the shortcomings of materialism is so substantial that an increasing number of articles and books are being written on this subject [1, 7, 8, 9]. In fact, this has contributed to the emergence of a whole post-materialistic movement in recent decades, which is exploring what this new paradigm might look like [3, 9, 10, 11, 12]. Believe it or not, you can also find a manifesto for post-materialistic science [13].

3 Cognitive Science under Analytical Idealism

One of the proponents of the post-materialistic movement is Bernardo Kastrup, who advocates for Analytical Idealism [3]. Analytical Idealism posits that consciousness is the fundamental essence of reality, rather than matter [12]. The focus of this summary is not to provide a detailed description of Idealism, but rather to explore the potential changes in the methodology of scientific research that could result from adopting this perspective.

3.1 Two distinct routes to knowledge

Changes in ontological views lead to changes in scientific methods as they alter the foundational concepts and relationships that guide inquiry [14]. If consciousness is indeed a fundamental aspect of reality rather than a byproduct of neural activity, it implies that consciousness might directly access aspects of reality without relying solely on sensory perception [15]. This leads us to consider two distinct routes to knowledge: conventional sensory perception (science as it is mainly now) and a more direct introspective approach. Walach calls this approach “radical introspection.” Radical introspection involves a deep inward focus, often achieved through contemplative and meditative practices. Unlike standard qualitative introspection, which relies on external referents (e.g., transcripts, observations), radical introspection does not have such referents beyond personal experience. It faces challenges of subjective bias and lack of established methodology for validating truth claims. However, it remains a crucial aspect of potential new methodologies in science, requiring the development of techniques to record, communicate, and verify first-person experiences.

At this point, it is important to highlight that Walach is not the only proponent of integrating radical introspection into scientific inquiry. Kordeš [16] arrives at a similar conclusion in his arguments, even though he does not refer the concept of idealism at all. He suggests that in-depth, existentially liable introspection and self-inquiry should be considered as serious scientific research tools.

3.2 Combining first and third person research

When looking at current scientific practices, we can see some early attempts in that direction. The godfather of this approach is, of course, Francisco J. Varela [17]. From this approach emerged the field of contemplative neuroscience, which explores individuals in altered states of consciousness that develop through various contemplative practices. This field seeks to integrate traditional third-person scientific methods, such as MRI, EEG, and MEG, with first-person accounts of personal experiences in these altered states of consciousness [18, 19, 20]. When we start taking contemplative and meditative practices seriously, science can begin to exchange ideas with ancient traditions such as Buddhism, Hinduism and others. Even this is already happening [21, 22, 23].

3.3 The consequences of such a research approach

This interdisciplinary exchange highlights the potential for scientific and spiritual perspectives to enrich each other and expand our understanding of consciousness and reality. Additionally, to broaden scientific inquiry, spiritual practices like meditation and contemplation can be secularized and incorporated into the scientific process. Fun fact, At the 6th International Colloquium of Cognitive Sciences, Dr. Berkovich-Ohana began her presentation titled "Meditation and the Self: Neuroscience and Phenomenology" with a few minutes of guided meditation [24]. By integrating these practices, scientists could benefit from improved mental hygiene, enhanced creativity, and increased cognitive capacities [25], [26], [27].

This step can be highly significant, as it enhances the performance of researchers. A greater focus may lead to reduced bias, while increased creativity fosters better hypotheses, ultimately resulting in more effective research. Such advancements are essential for achieving substantial breakthroughs.

Engaging in meditation and/or contemplative practices poses potential downsides for scientists, too. First, the focus on personal experience conflicts with the concurrent objective standards required in scientific research. While self-research can yield valuable insights, its subjective nature can lead to biases that undermine intersubjectivity. Furthermore, the personal transformation that occurs during deep self-reflection may distract researchers from maintaining the rigorous, detached perspective typically expected in scientific inquiry. Ultimately, the integration of such practices into mainstream science remains challenging, as it contrasts with the traditional role of researchers.

4 Conclusion

In conclusion, I would like to emphasize a few key points. First, the entire described methodology can, of course, be applied from a materialistic standpoint as well. It is not the ontology itself that matters; rather, it is the methodology that enables insight. Materialists can also engage in contemplative neuroscience. Second, year by year, we have more scientific studies suggesting that the current mainstream paradigm may be flawed. Let us carefully examine the data and avoid dismissing it simply because it contradicts our preconceived assumptions [28]. Third, if more scientists were to engage in meditation-like practices, this would generally benefit the scientific community for reasons previously discussed. Fourth, when we establish a connection between science and religion, mutual learning can begin.

ABSTRACT.
The rapid advancement of artificial intelligence is significantly enhancing human capabilities, even as human progress itself appears to stagnate, hindered by decadent ideologies and adverse societal trends. Over the past few decades, AI has achieved remarkable milestones, from mastering complex games to revolutionizing industries such as healthcare and finance through advancements in machine learning, natural language processing, and robotics. A particularly notable achievement is the development of GPT models, which have set new standards in language generation and expanded the horizons of AI's potential. This paper examines the impact of AI on various sectors, including societal and individual cognitive advancements, highlighting both the opportunities and challenges of widespread AI adoption. The discussion focuses on the transformative power of AI technologies and the ethical, economic, cognitive, and social implications of this ongoing revolution. As AI continues to drive innovation and transform industries, humans are increasingly integrating with these technologies through the pervasive use of smartphones, personal computers, and wearable devices. This integration has already enhanced our cognitive and functional capabilities, effectively amplifying human potential. However, as AI's influence on human life deepens, critical questions arise about the future of this symbiotic relationship and the trajectory of societal progress.

POVZETEK
Hitri napredek umetne inteligence izboljšuje človeške zmožnosti, medtem ko se zdi, da človeški napredek stagnira, oviran z dekadentnimi ideologijami in negativnimi družbenimi trendi. V zadnjih desetletjih je UI dosegla izjemne mejnike, od obvladovanja kompleksnih iger do revolucije v panogah, kot sta zdravstvo in finance, z napredki na področju strojnega učenja, obdelave naravnega jezika in robotike. Posebej pomemben dosežek je razvoj modelov GPT, ki so postavili nove standarde v generiranju jezika in razširili obzorja potenciala UI. Ta članek preučuje vpliv UI na različne sektorje, vključno z družbenim in individualnim kognitivnim napredkom, ter poudarja tako priložnosti kot izzive, ki jih prinaša široka uporaba UI. Razprava se osredotoča na transformativno moč UI tehnologij ter na etične, ekonomske, kognitivne in družbene posledice te tekoče revolucije.

Medtem ko UI še naprej spodbuja inovacije in preoblikuje industrije, se ljudje vse bolj integrirajo s temi tehnologijami prek vseprisotne uporabe pametnih telefonov, osebnih računalnikov in nosljivih naprav. Ta integracija je že okrepila naše kognitivne in funkcionalne sposobnosti ter učinkovito pomnožila človeški potencial. Ko vpliv UI na človeško življenje narašča, se pojavljajo ključna vprašanja o prihodnosti tega simbiotičnega razmerja in o smeri družbenega napredka.

KLJUČNE BESEDE

1 Introduction

The rapid development of artificial intelligence (AI) is transforming industries and redefining/improving the essence of human capabilities. While AI progresses at an unprecedented pace, human societal progress appears to be stagnating, increasingly entangled in decadent ideologies and negative societal trends. This duality between AI's rise and human inertia is critical to understanding the current technological landscape. Over recent decades, AI has achieved remarkable milestones, including mastering complex games like Go and chess, advancing natural language processing (NLP), and driving significant innovations in sectors such as healthcare and finance. For example, the development of GPT (Generative Pre-trained Transformer) models represents a breakthrough in AI's ability to

generate human-like text, setting new standards for machine language generation and understanding [1, 2].

This paper examines the transformative potential of AI across various sectors, including healthcare, finance, education, and entertainment, highlighting both the opportunities and challenges that accompany widespread AI adoption. In recent years, significant advancements in AI have occurred at an accelerating rate. For example, breakthroughs in reinforcement learning and unsupervised learning have expanded the capabilities of AI systems, with applications ranging from autonomous vehicles to sophisticated recommendation systems [3]. Additionally, the ethical, economic, cognitive, and social implications of AI's proliferation are increasingly coming to the forefront, as debates intensify over issues such as algorithmic bias, privacy, and the potential for AI to displace human jobs [4]. These discussions underscore the need for robust governance frameworks to ensure that AI technologies are developed and deployed responsibly [5].

As AI technologies like machine learning, NLP, and robotics continue to evolve, they increasingly integrate into human life, augmenting cognitive and functional abilities through ubiquitous technologies such as smartphones, personal computers, and wearables. This integration, often referred to as a form of human-AI symbiosis, has already multiplied human potential, enabling tasks and processes that were previously unimaginable [6]. The consequences of this symbiotic relationship are profound, raising critical questions about the direction of societal progress and the future of humanity as AI [7, 8] becomes more embedded in everyday life.

We analyze the implications of AI's rapid development, particularly the considerations that must be addressed to navigate the ongoing AI revolution effectively. By integrating recent scholarly insights with a broader analysis of AI's impact, this paper seeks to contribute to the understanding of how AI is reshaping industries and human capabilities, as well as the future trajectory of this unprecedented technological evolution.

2 AI progress

A recent and transformative achievement is the development of Generative Pre-trained Transformers. These models represent a leap forward in natural language processing, capable of generating human-like text, translating languages, and even writing code. The GPT-3 model, released by OpenAI in 2020, is particularly notable for its ability to perform a wide range of tasks with minimal input, showcasing the power and versatility of large-scale language models [9].

Here we present one major achievement over the last five years, having in mind the constant AI progress in areas like autonomous driving or pattern recognition:

2019: AlphaStar in Real-Time Strategy Games

In 2019, DeepMind's AlphaStar achieved a significant milestone by reaching the top players of professional StarCraft II play, a complex real-time strategy game that requires long-term planning, resource management, and real-time decision-making. This achievement underscored the potential of AI to operate in dynamic and highly strategic environments, far beyond turn-based games like Go [10].

2020: GPT-3

The release of GPT-3 by OpenAI in 2020 marked a significant advance in the field of NLP. GPT-3, with 175 billion parameters, demonstrated unprecedented language generation capabilities, performing tasks such as translation, summarization, and question-answering with high proficiency and minimal fine-tuning. It set a new benchmark for the potential of AI in creative and linguistic tasks [9].

2021: DeepMind's AlphaFold 2 in Protein Folding

In 2021, AlphaFold 2, developed by DeepMind, solved one of biology's greatest challenges by predicting protein structures with remarkable accuracy. This breakthrough has significant implications for drug discovery, understanding diseases, and designing new biological processes, demonstrating AI's potential to revolutionize the life sciences [11].

2022: DALL-E 2 and Image Generation

OpenAI's DALL-E 2, released in 2022, demonstrated the power of AI in generating highly detailed and creative images from text descriptions. This model pushed the boundaries of AI in the visual domain, showcasing its ability to combine artistic creativity with technical precision, and opening new possibilities in design, marketing, and entertainment [12].

2023: GPT-4 and Multimodal AI

In 2023, OpenAI introduced GPT-4, which expanded the capabilities of its predecessor by being multimodal—able to process and generate both text and images. GPT-4's ability to handle complex queries across different formats has made it a powerful tool for applications in education, customer service, and creative industries, further blurring the distinction between products of human and machine intelligence [13].

The last five years have seen groundbreaking AI achievements each year that have pushed the boundaries of what AI can do. From mastering strategic games and understanding protein structures to generating high-quality text and images, AI's progress continues to accelerate, bringing us closer to a future where AI plays an integral role in nearly every aspect of society. In the next section, we examine human progress.

3 Impact of AI progress across various fields

As AI continues to evolve, its influence is expected to permeate multiple sectors, driving innovation and transformation. This section analyzes the potential impact of AI across key fields such as healthcare, finance, education, entertainment, and transportation, highlighting both the opportunities and challenges these advancements may bring.

Healthcare: AI has the potential to revolutionize healthcare by improving diagnostics, personalized medicine, and patient care. Machine learning algorithms are already being used to analyze medical images with greater accuracy than human radiologists, and AI-driven predictive analytics are helping to identify at-risk patients before conditions worsen. Additionally, AI can streamline administrative processes, reducing the burden on healthcare professionals and allowing for more efficient patient management. The integration of AI in healthcare is expected to lead to better patient outcomes, lower costs, and a more proactive approach to health management [14]. The JSI team is in the last phases of donating a home doctor system to all Slovenians.

Finance: The finance industry is experiencing significant transformations due to AI, particularly in areas such as algorithmic trading, risk management, and fraud detection. AI algorithms can analyze vast amounts of financial data in real-time, enabling more informed and faster decision-making. These technologies also enhance the accuracy of credit scoring and personalized financial advice, offering tailored solutions to individual customers. However, the increased reliance on AI also raises concerns about market stability, ethical use of data, and the potential for systemic risks [15].

Education: AI is poised to transform education by providing personalized learning experiences, automating administrative tasks, and enabling new forms of interactive learning. AI-driven adaptive learning systems can tailor educational content to the needs of individual students, allowing for more effective learning outcomes. Additionally, AI can assist teachers by automating grading and providing real-time feedback, freeing up more time for personalized instruction. GPTs further offer significant improvements in education. Integrating AI in education also presents challenges, such as ensuring equitable access to AI-driven tools and addressing concerns about data privacy [16]. At JSI, we tested the quality of various GPTs on educational tasks.

Entertainment: The entertainment industry is undergoing a significant shift due to AI's capabilities in content creation, recommendation systems, and audience engagement. AI-generated music, art, and scripts are becoming increasingly sophisticated, thus differentiating between products of human and machine creativity as often impossible. Recommendation algorithms, powered by AI, personalize content delivery to users, enhancing their experience and increasing engagement. However, this rise in AI-generated content raises questions about the future of human creativity and the potential for AI to disrupt traditional content production models [17]. Recommendation algorithms were one of the central parts of the H2020 smart-city Urbanite project with most of the software developed at AI.

Transportation: AI is driving innovation in transportation through the development of autonomous vehicles, smart traffic management systems, and predictive maintenance. Self-driving cars, powered by AI, promise to reduce accidents, lower emissions, and increase the efficiency of transportation networks. AI can also optimize traffic flow and reduce congestion through real-time data analysis and adaptive traffic control systems. However, the widespread adoption of AI in transportation faces challenges related to safety, regulatory frameworks, and public acceptance [18].

In the next section, human progress and integration with AI are presented.

4 Human progress including merging with ICT and AI

4.1 Historical overview of human progress

Human progress is a story of relentless evolution and technological advancement, spanning millions of years. Beginning around six million years ago, the earliest hominins diverged from the common ancestor we share with chimpanzees, marking the start of a journey toward modern humanity. One of the earliest major milestones was the development of bipedalism, which allowed early humans to travel long distances and use their hands for tool-making. The invention of tools around 2.6 million years ago further distinguished our ancestors, enabling them to manipulate their environment in unprecedented ways.

Approximately 200,000 years ago, Homo sapiens emerged, equipped with greater cognitive abilities and complex language, facilitating social structures and cultural developments that set the stage for future innovations. The advent of agriculture around 10,000 years ago marked a fundamental shift in human society, leading to settled communities and the eventual rise of civilizations.

Fast forward to the Industrial Revolution in the 18th century, human progress accelerated dramatically. Innovations in machinery, transportation, and communication reshaped societies, laying the groundwork for the Information Age. The 20th century saw rapid technological advances, including the development of the computer, the internet, and the beginnings of artificial intelligence, all of which have profoundly impacted human life.

4.2 Recent progress: merging with ICT and AI

In the past few decades, the convergence of information and communication technologies (ICT) and artificial intelligence has fundamentally altered the trajectory of human progress. This merger has enhanced human capabilities and begun to blur the lines between human and machine intelligence, creating a symbiotic relationship reshaping society.

Mobile Phones: One of the most transformative technologies of the late 20th and early 21st centuries is the mobile phone. Introduced commercially in the 1980s, mobile telephones rapidly evolved from simple communication devices to powerful, multifunctional tools. The advent of smartphones in the 2000s, with their integration of internet access, GPS, and a multitude of applications, significantly enhanced human connectivity and access to information. Today, smartphones are essential tools for both personal and professional life, facilitating real-time communication, social networking, and a vast array of digital services [19].

The Internet and Cloud Computing: The development of the Internet in the late 20th century and the rise of cloud computing in the early 21st century have revolutionized how humans interact with information and each other. The internet has democratized access to knowledge, enabling global communication and collaboration, while cloud computing has made vast computational resources and storage available to individuals and organizations alike. These technologies have increased productivity and laid the foundation for the widespread deployment of AI systems, which rely on large datasets and significant computational power [20].

Generative Pre-trained Transformers: The recent advancements in AI, particularly with the development of GPTs, represent a significant leap in the merging of human capabilities with machine intelligence. GPT-3, introduced in 2020, demonstrated the ability to generate coherent and contextually relevant text based on minimal input, performing a wide range of tasks such as translation, summarization, and even creative writing. GPT-4, released in 2023, expanded on this by incorporating multimodal capabilities, processing both text and images, and further enhancing human-machine interaction [13]. These models are not just tools but extensions of human

cognitive abilities, enabling users to perform tasks that require complex reasoning and linguistic skills with the assistance of AI.

Wearable Technology and Augmented Reality: Wearable devices, such as smartwatches and fitness trackers, have integrated AI into daily life, monitoring health metrics and providing real-time feedback to users. These devices exemplify the merging of human biology with technology, offering new ways to enhance physical and cognitive performance. Augmented reality (AR) technologies are also becoming increasingly prevalent, overlaying digital information onto the physical world and creating immersive experiences that enhance learning, navigation, and entertainment [21].

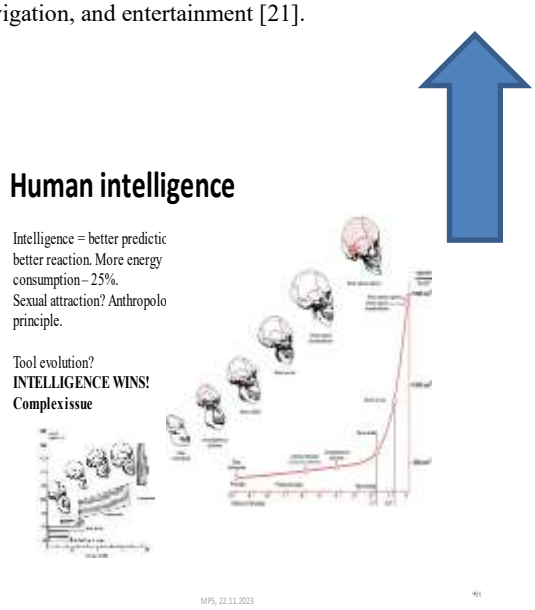

Figure 1: Progress of the human brain and intelligence. Source of the draft (modifications original): https://www.aquatic-human-ancestor.org/anatomy/brain.html

Human progress, from the earliest hominins to the modern age, has been marked by the continuous development and integration of technologies that enhance human capabilities. In recent decades, the merging of ICT and AI with human activities has accelerated this progress, creating a symbiotic relationship that extends human cognitive and physical abilities. Technologies such as mobile phones, the internet, GPT models, and wearable devices have not only transformed how we live and work but have also set the stage for future advancements that may further blur the lines between human and machine intelligence.

The key idea of this overview is that humans and user interfaces are already deeply intertwined, both through physical hardware like mobile phones and more abstract systems such as software and information networks. As these systems fast become more sophisticated, they enhance human cognitive, intellectual, and mental functions, effectively expanding our capacities. This growing interconnection between humans and technology echoes the concept of *cyborgization*, where external devices supplement and expand the functions of the human mind. The development of smartphones, wearable technology, and even future brain-computer interfaces suggests that this synergy is only deepening. Contrary to claims that our brain size is deteriorating, the measure of human intellectual capacity should now include not just our innate abilities but also the external systems that augment them [19].

The view that technology significantly enhances human cognitive ability aligns with Harari's notion of humans becoming "cyborgs" as they increasingly rely on tools that supplement mental processes. Similarly, [22] discusses the extended mind theory, which posits that external tools, such as smartphones, are integral components of the human cognitive system, challenging the notion that brain size or biological limitations strictly define mental capacity. These technological extensions of human cognitive ability have created new frameworks for evaluating our intellectual potential, making it more accurate to assess human functionality in a combined system of biological and technological entities.

The emergence of human-like properties such as consciousness [23], observed in advanced GPT models, represents a pivotal step in the evolution of artificial intelligence and human progress. These models, capable of understanding and generating natural language, are beginning to mimic forms of cognitive processes, thus contributing to what could be described as the dawn of a new "intelligent era." This era, driven by AI's ever-increasing capabilities, promises a deeper integration between human cognition and machine intelligence, potentially fostering innovations in problem-solving, creativity, and the expansion of knowledge.

Researchers like David Chalmers have explored the idea that AI systems, such as GPT models, may embody elements of extended cognition, which can extend human cognitive abilities beyond their biological limits. The more these models evolve, the more they may contribute to an era where AI complements human intelligence in unprecedented ways, leading to new forms of civilization that heavily rely on intelligent systems to solve complex global challenges [7, 22].

Figure 1 illustrates the functional growth of human problem-solving capabilities, driven by the integration of ICT and AI solutions, which serve as amplifiers of natural intelligence. Human cognitive abilities are being multiplied several times through this merger with ICT and AI, as represented by the blue arrow. While the original figure without the blue arrow shows the increase in human skull volume, and thus brain size, the blue arrow highlights the exponential growth in problem-solving capacity. A simple analogy can be drawn: consider a person walking barefoot versus using a car or plane. The speed of movement changes dramatically, even though the human's physical body remains unchanged. Similarly, while human biology (the brain) did not improve, the ability to tackle complex tasks surged drastically with the aid of ICT and AI

5 DISCUSSION

In recent years, there has been growing concern that Western civilization is experiencing a period of decline, marked by political fragmentation, cultural disintegration, and economic challenges. Scholars have pointed to a loss of social cohesion, declining institutional trust, and the rise of non-productive and conflicting ideologies [24, 25].

On the other hand, the rapid advancements in artificial intelligence are driving unprecedented changes across various

fields, fundamentally altering the landscape of industries and society. As AI technologies continue to evolve, they offer both tremendous opportunities and significant challenges that require careful consideration.

Balancing Innovation with Ethical Concerns: One of the primary discussions surrounding AI is the balance between innovation and ethical considerations. AI has the potential to revolutionize fields like healthcare, finance, education, and transportation by improving efficiency, accuracy, and personalization. However, these advancements also raise critical ethical questions, particularly regarding data privacy, algorithmic bias, and the potential for AI to perpetuate or exacerbate existing inequalities. For example, while AI-driven personalized medicine can enhance healthcare outcomes, it also risks marginalizing those without access to the necessary technology or data [14].

Moreover, the use of AI in finance, particularly in areas like algorithmic trading and credit scoring, has the potential to deepen economic disparities if not carefully regulated. The challenges of ensuring fairness, transparency, and accountability in AI systems are significant and demand robust governance frameworks to prevent misuse or unintended consequences [15].

The Human-AI Symbiosis: Another crucial aspect of the discussion is the growing symbiosis between humans and AI. As humans increasingly rely on AI technologies in daily life—through smartphones, wearables, and AI-powered applications—there is a merging of human and machine capabilities. This integration has the potential to significantly enhance human cognitive and physical abilities, leading to what some describe as an augmented human experience. However, this symbiosis also raises questions about dependency, control, and the future of human autonomy. As AI systems become more embedded in decision-making processes, it is essential to consider how these technologies may influence human behavior, decision-making, and even identity.

The development of AI models like GPT-4o has shown how closely intertwined human and machine intelligence can become. These models have not only expanded the possibilities of human-machine interaction but have also challenged our understanding of creativity, communication, and the nature of intelligence itself. As AI continues to evolve, it will be crucial to monitor and understand the long-term implications of this symbiotic relationship on human society and culture [13].

The author of this paper continuously highlights the significance of this merging, noting that the increasing integration of AI into human life first of all augments human capabilities but also to a certain degree presents complex ethical and philosophical challenges. As AI begins to mirror human-like consciousness in certain aspects [22], the line between human and machine products is becoming increasingly blurred, raising questions about the future of this relationship and the implications for human identity and autonomy [23]. The level of consciousness in large language models (LLMs), evaluated through Tononi's axioms of intelligence, was found to be significantly below that of human consciousness, but notably improved compared to earlier AI systems [23].

The Future of Work and Society: AI's impact on the workforce is another critical area of discussion. While AI can enhance productivity and create new opportunities, it also poses a significant threat to traditional job roles, particularly in industries where automation can replace human labor. This shift could lead to widespread job displacement, necessitating a rethinking of economic structures, education systems, and social safety nets to address the needs of a rapidly changing labor market [16].

The potential for AI to drive social and economic inequality is a pressing concern. Without proactive measures to ensure equitable access to AI technologies and to address the disparities that may arise from AI-driven economic shifts, society risks deepening existing divides. One of the best solutions is introducing the AI courses already in elementary schools.

Navigating the AI Revolution: As AI continues to advance, society is at a crossroads, faced with the task of navigating the complexities of the AI revolution. The potential benefits of AI are immense, but there are also certain risks. Ensuring that AI technologies are developed and deployed responsibly will require a concerted effort from governments, industry, academia, and civil society. This includes developing ethical guidelines, regulatory frameworks, and educational initiatives that can help society adapt to the changes brought about by AI. At the same time, these regulations should first of all enhance proper progress, research and development, and not pose additional bureaucratic burdens.

In cognitive terms, GPT models represent a promising approach to creating forms of artificial consciousness and cognitive information beings. These models simulate aspects of human cognition, such as language understanding and generation, by mimicking neural networks that resemble the processing of human brains. As they evolve, GPTs could potentially help us explore and understand the fundamental components of human consciousness, offering insights into both artificial and human cognition [26].

In conclusion, the discussion surrounding AI is multifaceted, touching on ethical, social, economic, and technological dimensions. As we advance, it is essential to balance harnessing AI's potential with addressing the challenges it brings, such as bias, privacy concerns, and the risk of job displacement. By proactively engaging with these issues, we can ensure that the AI revolution creates a future that is not only innovative but also promotes individual and societal human progress. Despite the ongoing debates and misunderstandings, the transition toward an information-driven era seems inevitable, as AI continues to integrate into every facet of human life, shaping our collective destiny.

Tool Usage: ChatGPT-4o and various grammar and word processing tools were applied to enhance the language quality. ChatGPT was also employed periodically to refine informal draft ideas into well-structured, formal text. The text was regardless of the language modifications finally examined and modified by the author.

Cognitive perspective on production of third person dative and accusative clitic pronouns in Slovenian school-aged children

Maruša Brežnik Dornik
Center for Cognitive Science of Language
Faculty of Humanities
University of Nova Gorica
marusa.breznik@ung.si

Abstract

The paper investigates the production of third-person dative and accusative clitic pronouns in Slovenian school-aged children, focusing on whether cognitive factors influence their acquisition, despite the morphological similarities of these clitics in Slovenian. Previous research in Italian suggested that dative clitics in Italian are acquired earlier than the accusative due to their morphological differences, a pattern tested within the Slovenian context. Using elicited production tasks with 71 Slovenian children, the study reveals that in Slovene third person clitics are produced more frequently than third dative clitics, challenging the idea that acquisition is driven solely by morphological complexity. The research is framed within cognitive science, drawing on Universal Grammar and connectionist models to explore how cognitive processes, such as working memory and language processing demands, interact with linguistic structures.

Keywords

Language acquisition, Slovenian clitics, dative, accusative, pronouns

1 Introduction

Language acquisition is a fundamental aspect of cognitive development, providing a window into how and when the human mind processes and structures information. The acquisition of clitic pronouns, such as the third person dative (3DAT) and accusative (3ACC) clitics in Slovenian, involves complex cognitive processes that reflect both innate linguistic capacities and the influence of environmental factors. In the first part, this assignment explores these processes through the lenses of prominent cognitive science theories, including Universal Grammar and connectionist models, while also considering the role of working memory in language development. In the second part, the conducted experiment, which tested proposed research hypothesis from Italian on Slovenian school-aged children, is presented**.**

2 Experiment

Cardinaletti et al (2021) claim that the Italian dative clitics are acquired faster than their accusative counterparts because of a morphological difference between Italian dative and accusative clitics. Since there is no comparable difference between Slovenian dative and accusative clitics, their proposal predicts that the observed difference in acquisition should be absent in Slovenian. I tested this prediction among Slovenian children. The prediction was not confirmed, since children produced 3DAT clitics significantly less often than 3ACC.

2.1 Goals and predictions of the study

This study aims to examine the production of 3DATand 3ACC clitic pronouns among Slovenian school-aged children. Acquisition of the two clitic pronouns had been studied in Italian, where it was determined that the acquisition of the 3DAT clitics precedes the acquisition of 3ACC clitics [3]. The authors argue that the difference in the time of acquisition stems from different morphological makeup of the two sets of clitics. Italian dative clitics do not differentiate between gender (*gli* is a third dative pronoun used for both feminine and masculine gender), while accusative clitics differ for the two genders and are thus morphologically more complex. They argue that gender features, or better the lack of them, must be the reason why Italian children produced more 3DAT clitics than 3ACC clitics.

In Slovenian both 3ACC (ga “him”, jo “her”) and 3DAT (mu “to.him”, ji “to.her”) clitics are comparable in their morphological complexity as they both also spell-out the gender feature. Given the analysis in [3] it is predicted that there should be no difference in the production of 3ACC and 3DAT clitics in Slovenian. The purpose of this research is to test this prediction by exploring whether there is a difference in the production of 3ACC and 3DAT clitics among Slovenian school-aged children.

2.2 Methodology

The methodology for this study is structured around two main elicited production tasks, each tailored to evaluate the production

of dative and accusative clitic pronouns in Slovenian. These tasks are adapted from those used in the study [3], ensuring consistency in approach while accommodating the unique aspects of Slovenian. Slovenian stimuli consist of translations, and where necessary, adaptations of the Italian sentences used in [3] and of mostly unmodified drawings also from [3].

2.3 Participants

71 Slovenian typically developing (TD) children took part in the study. They were divided into six age groups, as shown in the table 1. Written in- formed consent was obtained from the children's parents prior to testing. Parents provided information about the languages spoken at home, which enabled us to exclude bilingual and L2 Slovenian speakers from the study.

Table 1: Groups, age and mean age of tested children.

Groups	Age	Mean age
TD1	6.6-6.9	6.8
TD2	7.0-7.9	7.4
TD3	8.0-8.8	8.6
TD4	9.0-9.9	9.6
TD5	10.0-10.8	10.4
TD6	11.0-11.9	11.4

Elicited Production – Accusative Task

This task is designed to elicit the use of 3ACC clitic pronouns. Children were presented with a series of visual stimuli featuring one or two characters engaged in various actions. For each set of images, the initial scene was described to the child using a recorded narrative. Following this, a second image was shown, and the child was asked to describe the action occurring, specifically focusing on the interaction between the characters. The aim is to prompt responses that naturally incorporate accusative clitic pronouns, reflecting the child's understanding and use of these grammatical structures.

Example Stimulus for Accusative Task

The first drawing shows a boy (agent) destroying a sand castle (patient), (Figure 1). The narrative describes the first scene, and the child is asked, "What is the boy doing to the castle?" (Figure 2). The expected response should include the accusative clitic pronoun corresponding to the castle sand, indicating the action directed towards the patient.

Figure 1: "In this story there is a boy that wants to destroy a sand castle."

Figure 2: "Look, what is he the boy doing to the castle?"

Similar elicited production task was made for the dative.

2.4 Procedure

Each child participant was individually tested in a quiet room within their school, ensuring a comfortable and distraction-free setting. All responses were audio- recorded and subsequently transcribed for analysis, with verification by two separate reviewers to ensure accuracy.

2.5 Response coding

We have classified the answers into three categories: target, production of full noun phrases (NP), clitic/NP omission. Every answer containing a clitic pro- noun was considered as target. Children have produced a good amount of target answers. In most of the answers they produced the same verbal form they had heard in the question, present tense, or sometimes produced sentences containing past tense. The most frequent non-target answer was the production of full NPs (in both, accusative and dative tests). The answers are grammatical, though redundant and pragmatically infelicitous, since the elicitation context requires clitic pronouns. There were some instances where clitics were omitted, either in the accusative or dative tests. In the accusative test, clitic omission led to ungrammatical sentences. In the dative test, ungrammatical responses occurred with verbs like *dati* "give," *podariti* "give," and *prinesti* "bring," all of which require a goal argument. Conversely, verbs such as *brati* "read" and *metati* "throw" resulted in grammatical sentences that were, however, contextually inappropriate for elicitation.

Table 2: Percentages of target answers for all groups

Groups	Target DAT	Target ACC
TD1	28,7	57,4
TD2	57,1	83,3
TD3	37,5	62,5
TD4	71,2	85,9
TD5	64,3	76,2
TD6	81,8	82,6

3 Results and discussion

All children's responses were compared using student t-test: the difference in the amount of 3DAT and 3ACC produced between the tested children is statistically significant ($p < .001$). Table 2 gives an overview of percentages of production of clitics, full NPs and omission in both tasks. Four instances of gender agreement error were found within the youngest group TD1 and two such errors within the TD3 group. Overall, children produced a good amount of target answers. The analysis within each group shows that the difference between 3DAT and 3ACC is noteworthy in all groups, except in TD6. The youngest groups produced significantly more 3ACC clitics than 3DAT clitics, namely TD1 28,7% more, TD2 26,19% more, TD3 25,0% more. As for the analysis between groups, we found significant differences for 3ACC, where the use of a 3ACC clitic is very low in TD1 group with 57,4%, TD3 group with 62,5% and TD5 with 76,19%. The omission was always higher with the 3DAT pronoun than 3ACC, TD1 omitted 3DAT with 16,67% more, TD2 with 25% more, TD3 with 8,34% more, in group TD4 no case of 3ACC omission was noted, TD5 omitted with significantly higher percentage of 20,23% more and TD6 with 4,54% more.

In this study the production of 3ACC and 3DAT clitic pronouns on Slovenian school-age children was tested, using two elicited production tasks. Differences between 3DAT and 3ACC clitics production were found in all groups. Children produced less 3DAT than 3ACC clitics in general. Which differs from what Italian kids (as reported in [1]) were producing, and also goes against the prediction based on [1]. Surprisingly the high omission is present in all age groups. Among the non-target answers, the production of full object instead of clitics was unusually high in the accusative task for the two oldest groups, while the four youngest groups produced fuller object in the dative task, which could be age related linked to the difficulty of the task. As Slovenian 3ACC and 3DAT clitics are morphologically comparably complex, the explanation provided in [1] cannot be used to explain the observed pattern.

The findings suggest that while innate linguistic capacities, as proposed by Universal Grammar, provide a foundation for language acquisition, the role of working memory and cognitive development cannot be overlooked. The results challenge the idea that the acquisition of clitic pronouns is driven solely by morphological complexity.

Acknowledgments

I am very grateful to Anna Cardinaletti, Sara Cerut and Francesca Volpato for sharing with me and allowing me to use their stimuli (drawings and Italian sentences) from [1]. I am grateful to the Elementary schools in Deskle and Celje that assisted me in running the experiment. This research was partially funded by ARIS grants N6-0314 and P6-03.

ABSTRACT

This study explores the effectiveness of a nudge-based intervention, to reduce cigarette butt littering on a student campus. Using the principles of nudge theory, particularly the EAST framework, we designed a ballot box, allowing smokers to "vote" by disposing of their cigarette butts. Observations conducted before and after the intervention revealed a statistically significant increase in proper disposal, supporting the claim that nudges can positively influence environmental behavior. However, the study also highlights several limitations, including varying participant demographics and the challenge of isolating the factors driving behavioral change.

KEYWORDS

nudging, environmental behaviour, gamification, littering

1 INTRODUCTION

1.1. Increasing Need for Innovative Solutions

With the increasingly dire consequences of climate change, the urgency to address the environmental degradation has never been greater. Among the myriad of issues contributing to this escalating problem, littering—particularly the improper disposal of cigarette butts—stands out as a significant, yet often overlooked, contributor. In 2019, of the estimated 6 trillion cigarettes, only a third were properly disposed of [1]. Cigarette butts (CBs) are composed of tightly packed microfiber bundles of cellulose acetate. Cellulose acetate is cellulose treated with acetic acid, which heavily impedes the biodegradability of CBs. During their decades-long degradation period, CBs pose a double threat. The first is plastic pollution, as cellulose acetate is classified as a 'bio-plastic' with the second being the release of toxins that build up through the process of smoking [1]. The effects typically result from leaching, causing damage to aquatic life and contaminating waterways, while the consequences in terrestrial environments range from ingestion of butts, buildup of toxic chemicals, and soil contamination [1, 2, 3]. As such, finding ways to encourage proper disposal of CBs is crucial for reducing environmental harm.

1.2. Nudge Theory

One promising line of research in reducing littering is the nudge theory, first proposed by Thaler and Sunstein in their work *Nudge: Improving Decisions About Health, Wealth, and Happiness.* In their words, a nudge is "any aspect of the choice architecture that alters people's behaviour in a predictable way without forbidding any options or significantly changing their economic incentives" [4]. A nudge replaced their previous idea of paternalism, which similarly influences "choices of selected parties in a way that will make them better off" [5]. Several studies have found that nudges, in their various forms, can indeed be effective in reducing littering [6, 7, 8]. For example, a study on Chinese workers found that it is possible to reduce littering on the factory floor by 20% by placing golden coins, which are culturally and religiously significant, on the factory floor, thus changing it from a place that can be littered, to a place that should not be littered [8]. There are various forms of nudges and can be roughly divided into sizing (e.g. changing portion sizes in restaurants to reduce food waste), priming (e.g. footprints leading towards a bin), proximity (e.g. having a bin close by), presentation (e.g., designing eco-friendly devices as more aesthetic), labelling and improving the functional design [7]. Due to their diversity, usefulness and cost efficiency, nudges could help mitigate the environmental impact of CBs.

1.3. Theoretical framework

Our research was inspired and partly supported by the Green Nudge project[1]. This study specifically targeted the smoking behaviours of the student population from various faculties in the area of Kardeljeva ploščad in Ljubljana, aiming to assess how the design of bins could influence proper disposal habits of the CBs.

[1] The Green Nudge project ("UL za trajnostno družbo – ULTRA"), financed by the EU - NextGenerationEU, and Republic of Slovenia, Ministry of Higher Education, Science and Innovation.

In our pilot study we implemented the nudging principles in the context of pro-environmental behavior. During our research design and nudge implementation process we relied heavily on the ideas from The Little Book of Green Nudges [9], where we utilized their five recommended steps of nudge implementation and their EAST framework, designed to make a nudge Easy, Attractive, Social and Timely. We based our nudge on the findings of Rifkin and colleagues [10], where they found out that behavior, such as tipping in a bar, can be influenced by "dueling preferences". If a behavior is presented as a choice between two options, preference for dogs versus cats, it gives people the opportunity to self-express themselves through a behavior that is not directly connected with the preference. In a similar fashion we have designed a cigarette voting box, where people could cast a vote with their CBs. The previously mentioned study was also a basis for a pilot study by Gay and colleagues [11], where they compared the impact of different cigarette bins on polluting behavior. They found that a "dual preference" voting box, like ours, was the most efficient in reducing the pollution of the environment with CBs.

Figure 1: The ballot box for CB's
The prompts on the box are: morning shower (slo. *tuširanje zjutraj)* and evening shower (slo. *tuširanje zvečer*). The box is made from a repurposed mail box and is standing on a metal pole. Surrounding the box is a picture depicting two smokers. The bin was made by our colleagues at the Academy of Fine Arts.

Existing studies addressing cigarette butt littering through behavioural experiments indicate that 63% of such littering is driven by individual motivations, such as a lack of awareness about environmental impacts and the availability of ash receptacles [12]. Other contributing factors include convenience (e.g., the distance to bins) and habitual behaviour [13], some research highlights a correlation between an area's cleanliness and the likelihood of littering, with certain demographics, like younger individuals and men, being more prone to littering [14]. While the design of ballot bins is often consistent across studies, the specific environments, demographics, and timelines vary. Research demonstrates that these bins can be an effective, low-cost solution for reducing cigarette butt litter, particularly in more homogeneous settings like school campuses. However, their effectiveness may diminish in more diverse public spaces [14]. Given the many variables influencing these outcomes, researchers recommend further experiments to optimize these interventions in different settings [12, 13, 14].

2 METHODS

Our preliminary study into the effectiveness of cigarette disposal through the use of ballot bins was conducted on a student campus in Ljubljana, Slovenia during the spring and summer of 2024. After initially observing the campus area, we decided to target the behavior of throwing CBs on the ground. There were several 'hotspots' of discarded cigarette butts, but we were particularly intrigued by the large number of butts thrown around bins. What intrigued us was the fact that despite there being a clear area for throwing away their cigarettes, smokers still did not opt for this choice. As such, we focused on a popular smoking area of the Faculty of Social Sciences at the University of Ljubljana. During the span of six months, we conducted two sets of observations, totalling seven observations: one set of observations before our intervention and one after. The first four observations were carried out in April 2024 and observed a popular smoking spot for students and faculty next to an existing bin. With the exception of the first observation, which was done in a group by all researchers, all were done individually over the course of two hours. During these observations, we collected data on the total number of CBs thrown in the bin or improperly discarded. We also took into account other factors such as time of day, weather and any other factors we deemed important like the number of people smoking together outside, or any other factors, which might have influenced the final number. The second set of observations was done during July, this time with the nudge (the ballot box) placed next to the bin in a popular smoking spot. The ballot box can be seen in **Figure 1**.

3 RESULTS

Our descriptive results are presented in the table below (see **Table 1**), where we calculated the mean value of CBs either in the bin or on the ground before and after the implementation of our green nudge.

Table 1: Littering behaviour observations before and after intervention with CB's thrown in the bin and on the ground

Observations	Condition	CB's in bin		CB's ground	
		M	*SD*	*M*	*SD*
1	before	21	6.38	12.25	5.74
2	after	17	17.35	4.3	2.52

In order to determine if there is a statistical difference between the proportion of CBs in the bin versus on the ground based on the condition, we conducted a two-proportion Z-test. Based on

the statistical analysis we found that there was a statistically higher proportion of CBs thrown into the bin versus on the ground after the implementation of our cigarette voting box, compared with the proportions before its implementation, $z = 0.165$, $p = 0.0495$.

4 DISCUSSION

Based on our results we can confirm our hypothesis that our nudge would increase the proportion of CBs thrown into the bin versus on the ground thus reducing the pollution of the environment surrounding the student campus with CBs, which is in line with the findings by Gay and colleagues [11]. Although our results do indicate a change in the proportions, conclusions should be taken with caution, since the frequency of smokers present before and after the implementation of the nudge varied vastly and could have had a big impact on the results of our analysis.

Additionally, it is difficult to determine exactly what nudged the participants' behaviour, which opens a broader question of nudge validity. Specifically, for our nudge, there could have been a number of factors influencing their behaviour. Some of these factors include 1) proximity; simply having more available bins could have decreased the number of CBs thrown on the ground, 2) novelty; the nudge gained attention by simply being a new structure in a familiar environment, 3) presentation; the ballot box is more attractive than a conventional bin, which is why participants would decide for it. While these factors do not negate the effectiveness of the nudge, the difficulty in pinpointing the determining factor could influence the design and implementation of nudges. For example, if novelty is the determining factor, a green arrow pointing towards a bin could have the same effect as a costly ballot box. There is also a possibility that our nudge was not clear enough and thus resulted in some people not engaging with it. The communication materials were designed with a tone that was perhaps too playful and light-hearted, which may not have resonated well with the student population of smokers, who might have responded better to more straightforward and direct messages. This lack of clarity could have had an overall impact on the efficacy of our nudge as suggested by Sunstein [15].

4.1. Limitations

One key limitation of our study is the comparability of pre- and post-intervention data. Before the intervention, data was collected during the ongoing academic term with a larger, consistent student population. Post-intervention data, however, was gathered after the exam period, when fewer students were present. Moreover, the population mainly consisted of foreign students attending summer school. The study of Chinese workers by Wu and Paluck mentioned in section 1.2. urges that cultural context must be taken into account when designing a nudge. They state that nudges "must recognize motivations and subjective interpretations within a particular context" [8]. Thus, without the proper consideration of the cultural background of foreign students, it seems highly unlikely that our nudge, designed for Slovene students of the Faculty of Social Sciences, had an equal effect on foreign students attending summer school.

4.2. Future directions

While our pilot study provides valuable insights into the effectiveness of nudging towards pro-environmental behaviour, future research could address the small sample size in this study by employing a larger, more diverse population to improve the generalizability of the findings. Additionally, observing the population within a shorter timeframe would improve the validity of our results. Further studies could also include an interview before implementing a green nudge, using polling to determine the general environmental attitude, and after the green nudge, to ascertain the factors influencing their decision-making process.

In conclusion, our study has shown that nudges can be successfully employed to influence non-environmental behaviours by combining behavioural insights from nudge theory and gamification concepts (see [16] for a study combining gamification and nudging). Specifically, a ballot box could be used in short term settings, like open-air concerts and other events, where littering poses an issue. However, further research is needed to expand upon the factors underlying non-environmental decisions.

ACKNOWLEDGMENTS

This pilot research study was partly supported by The Green Nudge project ("UL za trajnostno družbo – ULTRA") - European Union - NextGenerationEU, and Republic of Slovenia, Ministry of Higher Education, Science and Innovation.

The authors also wish to express their gratitude to the development team at the Academy of Fine Arts, who created the ballot box.

Abstract

Achieving sustainability in today's complex world is a challenging, long-term endeavour. This paper focuses on the critical role of education in advancing sustainability, emphasizing the urgent need for innovative, interdisciplinary approaches that prepare students for the demands of both the modern and future world. Central to this discussion is the idea of problem-solving as a key to a sustainable future, which is deeply connected to the field of cognitive science. By leveraging insights from cognitive processes, researchers can develop innovative solutions to complex challenges, promoting resilience and adaptability in society. Understanding how individuals think and make decisions informs strategies for addressing pressing issues such as climate change, resource management, and social equity, ultimately contributing to sustainable development. By integrating insights from cognitive science—particularly in problem-solving, critical thinking, and metacognitive strategies—we highlight how these cognitive tools enhance students' abilities to tackle sustainability challenges. The paper examines key issues, relevant disciplines, and outlines a framework for shaping future education to effectively contribute to global sustainability efforts.

Keywords

problem solving, education, SDG, ESG, sustainability

1 Introduction

There is a global agreement that sufficient resources should be devoted to preserving, and improving in the amount possible, our society. Having in mind the complexity of our society in total, but also of its many components, this is certainly a rather demanding endeavour. Currently, as a combination of the long-term goals and the operational prescriptions, the Sustainable Development Goals (SDG) were formulated [1]. Closely related to these Goals is the concept relating environmental issues, social issues and corporate governance – ESG [2]. One may argue that each of the three involved notions encompass rather complex and large substructures.

SDG is collection of 17 goals, spanning different aspects of our society [1]. The Goal 4 – Quality Education is specifically devoted to education. But along with it, education is important for all other goals, having in mind that generally education contributes to transferring knowledge and experience between generations. In that way, education contributes both to latency of values and good practices in our society, as well as to their evolution and gradual improvement. It is not just that the learning process is important, but awareness of it is crucial for the reflective thinking needed to address the challenges of sustainability and complex systems.

In this paper, we focus on the stated role of education. In section two, we extract aspects of society that are currently too demanding for most educational approaches and are consequently insufficiently encompassed within the optimal form of education. Cognitive science plays a crucial role by exploring how individuals perceive, think, learn, and solve problems, providing a foundation for developing educational approaches that promote sustainability.

In sections three and four, we concentrate on education. In section three, we extract starting points for the development of an optimal form of education that substantially contributes to sustainability. The ability to solve problems, a key focus of cognitive science, is critical for navigating the unpredictable dynamics of complex adaptive systems, which characterize many contemporary challenges. In section four, we additionally emphasize the education for sustainable future and relate it to systems thinking. Critical thinking, another pillar of cognitive science, enables students to analyse global challenges such as climate change and inequality, making it essential for understanding the interconnected nature of these issues. We argue that the inclusion of systems thinking significantly contributes to the education for sustainable development. Section five provides the perspective and general guidelines for the

http://doi.org/10.70314/is.2024.cog.19

broader application of systems thinking in education. The last section concludes the paper.

2 Society as a complex system

Research of complexity and complex adaptive systems (CAS) broadened our understanding of characteristic dynamics in society and its parts, which includes cooperation and competition, emergence, bifurcations and deterministic chaos, to name some of the relevant notions [3, 4].

Dynamics of the CAS is characterized with nonlinear interactions, the important consequence of which is delay. That includes different aspects of dynamics, particularly the instabilities. Nonlinearity is a notion that can easily be described yet deserves significant experience to be considered properly, whether that be for predictions or for analysis of past events. CAS is modelled on the micro-level, by characteristics of entities, usually called agents, and rules of their interactions [5]. The macro-level, system behaviour is obtained by simulations. There is no direct linking between macro-level and micro-level. Instead, one modifies micro-level characteristics of agents and rules of their interactions to obtain specific macro-level system behaviour. Models differ in the level of stylization, so some reveal generic system behaviour, trends that can be related to many diverse systems [5], while others are specific and reproduce expected dynamics in detail but of a particular system. Some contributors emphasise anthropomorphic interpretation of quantities that are historically considered rather formal [6], while other develop formal approach to intrinsically human-related characteristics such as happiness [7, 8, 9], to mention few examples among a myriad of existing scientific contributions.

All stated should be taken into consideration if one wants to make reliable predictions for a society or some other CAS. That requires a critical mass of competent people, to be formed within every new generation by a well-formulated, learning outcomes oriented, profound education.

3 Education for complex systems

World Economic Forum states top 10 skills, for different periods since almost a decade ago. Consistently, critical thinking and complex problem-solving top the list of skills that employers believe will grow in prominence [10]. These have been consistently emphasized as crucial since the first report almost a decade ago. Moreover, broader application of ESG standards within organizations will also have a significant impact [10, 11]. One aspect is that investments that facilitate the green transition of businesses and the broader application of ESG standards bring about net job-creation [11].

OECD monitors education and different aspects of transition from school to work. In addition, OECD formulated and organizes world-wide testing of skills and knowledge among students, in the form of PISA testing [12, 13].

UNESCO has contributed extensively to the development of competences of children and youth [14]. It was realized some time ago that education for sustainable development is a key instrument to achieve the SDGs [14].

The UN previously proclaimed Decade of Education for Sustainable Development (2005–2014), aimed at integrating the principles and practices of sustainable development into all aspects of education and learning [14].

One of the consequences of the extensive testing of alignment of education with society's needs is that we have rather detailed and reliable insight into the fulfilment of the education potential. Yet, it is clearly stated in words by I. Bokova, General-director of UNESCO: "A fundamental change is needed in the way we think about education's role in global development, because it has a catalytic impact on the well-being of individuals and the future of our planet" [14].

All stated about the reached education level and characteristics of our society (and CAS as its models) point to the fact that an innovative, qualitatively different education is needed to include the complexity in formal curricula, so that students can grasp its fundaments in a significant portion.

As a particular aspect of education, we emphasize problem-solving. It is a set of actions aimed at solving a particular problem, no matter how complex, or interdisciplinary it is. However, that approach is not yet formulated precisely so its potential is realized only by a small part.

Along with the problem-solving skills, and critical thinking, it is crucial to embed metacognitive strategies in education. If students have learned to reflect on their own learning processes, they are better equipped to contribute meaningfully to the SDG-a and adapt to the complexity of modern society as a CAS.

4 Education for sustainable development

The ability to solve problems from the perspective of cognitive psychology is a crucial for achieving sustainability. Cognitive psychology, which studies mental processes such as perception, memory, thinking, and problem-solving, provides insights into how people make decisions and how they can be encouraged to adopt sustainable behaviours. Understanding how people process information and make decisions involves recognizing problems, generating possible solutions, evaluating those solutions, and selecting the most appropriate one. In the context of sustainability, these problem-solving skills are essential for individuals and communities to identify environmental challenges, develop innovative solutions, and implement sustainable practices [15].

Research has shown that human behaviour is a significant source of uncertainty in the use of natural resources and a critical factor in local and global sustainability challenges [16]. By integrating insights from behavioural sciences into sustainability research, we can develop policies that promote sustainable behaviour. Cognitive psychology provides tools to understand how people perceive environmental problems and how they can be motivated to change their behaviour [17].

Education plays a pivotal role in fostering these problem-solving skills. Education for sustainable development (ESD) equips learners of all ages with the knowledge, skills, values, and agency to address interconnected global challenges such as climate change, biodiversity loss, and resource depletion [18]. ESD empowers individuals to make informed decisions and take collective action to transform society and care for the planet [19].

To further enhance these educational efforts, system thinking is another critical element for achieving sustainability. System thinking allows us to see how different parts of a system interact and how changes in one part can affect the entire system [20]. By

understanding complex environmental problems through system thinking, we can develop holistic solutions that consider long-term consequences. This approach is integral to problem-solving as it helps identify the root causes of issues and their interconnections within the environmental system [21].

In addition to system thinking, STEM (Science, Technology, Engineering, and Mathematics) education is essential for sustainable development. STEM education equips individuals with critical thinking, problem-solving, and technical skills necessary to address environmental challenges. By integrating sustainability into STEM curricula, we can prepare future generations to develop innovative solutions for sustainable development [22, 23].

Moreover, a transdisciplinary approach is vital for sustainability. This approach involves collaboration between academics from different disciplines and non-academic actors to co-produce knowledge and develop actionable solutions. Transdisciplinary research addresses complex sustainability challenges by integrating multiple perspectives and promoting holistic understanding [24, 25].

The ability to solve problems from the perspective of cognitive psychology, combined with system thinking, STEM education, and a transdisciplinary approach, provides valuable tools for addressing environmental challenges and achieving sustainable development.

Before proceeding it is to be noted that any new concept or other type of change in education needs to be implemented in real time and space. Regarding time, there is a significant literature about structuration of time and about leisure time of children and youth, see e.g. [26, 27] and references therein.

5 Strategies for enhancing critical thinking and problem-solving skill's

Sometimes it is difficult for educational processes to determine which actions/methods due to the complex systems are successful, especially when we are talking about climate changes, how to integrate them into everyday life and how to receive feedback on the impacts at individual and collective levels [28]. This calls for initiatives to strengthen the link between education and science. To achieve exactly such initiatives, educational systems should use cognitive and educational strategies to foster innovative solutions, but in addition to this, implementation of gamification enhance engagement and motivation towards eco-friendly actions [29].

To be more precise, gamification can be a useful tool to teach students about sustainability in general [30], creating a gamified environment where students could be active citizens monitoring their impact on the environment and thus influence climate change and sustainability, which leads to fostering problem-solving skills, critical and analytical thinking and creating sustainable solutions.

Another strategy which can be implemented in educational system, which in its core supports the development of the individual as a critical participant of a particular system, is the metacognitive strategy. Metacognition as a concept of thinking about thinking [31], enhance critical thinking, problem-solving and finally adaptability in education [32]. Use of metacognitive strategies enables students to develop self-awareness, monitor their thinking process, and regulate their cognitive processes to be more accurate [31]. This is important when addressing complex, interdisciplinary challenges and CAS.

To be clearer, the following three dimensions of metacognitive strategies need to be implemented:

A) **Planning dimension**, students need to prepare themselves for problem-solving scenarios and thought processes, which helps clarify their understanding of the problem and outline an approach to solving it.

B) **Monitoring dimension**, students need to check and validate their comprehension of the problem-solving scenario through self-questioning, which sustains critical thinking. This step ensures continuous reflection on their knowledge, allowing them to adjust strategies based on real-time insights.

C) **Reflection dimension**, after completing the task, students need to analyse what they learned, reflect on the effectiveness of the strategies used, and consider improvements for future tasks. This helps students better understand the complexity of sustainability and develop a deeper understanding of how their learning strategies can evolve.

Therefore, sustainable education should also rely on metacognitive strategies, because in its concept it contains the skills of critical thinking, problem-solving, but also the sustainability of both the problem-solving scenario and the ecosystem that created the sustainable solution.

6 Methodology for implementing sustainable education

According to all previous stated, strategy for empowering sustainable educational system and people involved in it (students, teachers, principals, parents, local community) was created. It is based on the enrichment of school curricula with ESG principles, which ultimately strengthens the school's ecosystem and makes it sustainable, and it is built based on three dimensions.

First dimension of the program are students, which includes students in the local community as active participants and those who contribute to development and innovation through an interdisciplinary and transdisciplinary approach of teaching and learning. In this way, the education system enriches the local community with individuals who are ready to face the complex problems of the CAS, to solve them, and to improve already existing solutions. Second dimension of the program are the teachers. By strengthening their knowledge and skills, as well as by raising their awareness of problems and the possibility of active participation in solving them, teachers provide students with support in an appropriate and sustainable way.

Teachers need to collaborate with system beyond schools in the way that students can gather information, critically think about problems, give the scenario of solving specific problem and in the end implement possible solution. For this, teachers should have a support and life-long education. Third dimension of the program are parents, principals and local community, which, by raising awareness of the needs, problems and possibilities of innovation within the school's ecosystem and beyond, provide significant support to students and teachers in their development.

The ecosystem is then complete, which with its way of functioning provides sustainability because all participants are aware of learning protocols as well as improving or changing existing solutions.

7 Conclusion

The relationship between sustainable education and cognitive science is a profound and crucial one, as it merges the principles of mental processes with practical applications for addressing the complexities of our contemporary world. Cognitive science provides the foundation for understanding and developing educational strategies that foster sustainability. In this context, key cognitive concepts such as problem-solving, critical thinking, metacognition, and systems thinking play a significant role in shaping the approaches needed for sustainable development.

This paper highlights the critical role that education has both in the achieving sustainability in complex, nonlinear systems and in finding solutions to the contemporary problems. It emphasizes the urgent need for innovative and transdisciplinary educational approaches that prepare students for challenges that are expected from them to deal with. Key aspects include the importance of problem-solving skills, critical thinking, and metacognitive strategies. By integrating these elements into education, we equip future generations to address the complexities of sustainable development and complex adaptive systems.

In conclusion, the principles of cognitive science are deeply intertwined with the goals and strategies of sustainable education. Cognitive science provides a framework for understanding how students can effectively engage with the complexities of sustainable development and complex adaptive systems. The integration of these cognitive skills into educational curricula ensures that future generations are equipped with the mental tools necessary to address the pressing environmental and societal challenges of our time.

Ultimately, education for sustainable development, supported by cognitive science, fosters not only informed and capable individuals but also a more resilient and adaptable society.

Abstract

With this paper we aim to outline numerous gaps and other cracks that emerge when we start researching conscious experience through first and second-person research approaches. The terms used to name various gaps were chosen for the sake of coherence (with a pinch of playfulness). The main gap is the *chasm between two consciousnesses* which we are trying to bridge by an exchange of descriptions of our lived experiences. When we begin to turn our awareness to *what it is like* to be we begin to develop the skill and way of observing in which experience is created. We call this gap between our everyday attitude and phenomenological observation the *crevice of awareness* in which lies the act of becoming aware of an experience. After becoming aware of a certain layer of experience we reach the *fissure of description*, which represents the crack between the actual experience as perceived and the constructed linguistic concepts in which we try to convey what and how we perceived the experience. When a description of an experience has been produced, the researcher interested in investigating human experience is confronted with the *cranny of comprehension*. We relate this process of conveying our experience to another conscious being to the processes of translation and remind researchers of lived experience to be careful and weary of the interpretation that inherently shadows every translation.

Keywords

Background experience, Conscious experience, First-person research, Second-person research, Experiential translation.

1 Introduction

Upon delving into topics and discussions regarding our understanding of the mind, we inevitably reach one or another gaping chasm – the most notorious is even named the hard problem of consciousness. David Chalmers [1] points out that there is nothing we know more intimately than conscious experience but there is also nothing harder to explain. In this article we are not trying to explain conscious experience, but we are interested in exploring the process of explaining and describing our conscious experience to another human being – in this paper we call this process of reporting our subjective experiences *experiential translation*. The subjective aspects of thinking, perceiving and feeling are all states of experience that have a certain way in which we experience them. As Thomas Nagel [2] puts it, there is *something it is like* to be a conscious organism, and this *what is it like* to be another organism is, most likely always, over an insurmountable chasm between one conscious organism and another.

We aim to address this chasm that extends from one experiential being to another and explore the cracks that emerge when trying to explore and extend from one ridge to another. In this analogy the ridges of *the chasm between two consciousnesses* represent different conscious organisms, each with their own *what it is like* to be, and the chasm is the impossibility of reaching the exact *what is it like* of another being. In the field of first and second-person research of lived experiences, researchers are trying to bridge this chasm by collecting detailed descriptions of experience. We will argue that in the act of producing and collecting such descriptions we stumble upon many cracks, located on both sides of what we call *the chasm between two consciousnesses*. Starting from first-person view (as one should, when going about empirical phenomenology) we stumble upon a crevice that is becoming aware of *what is it like* to be – the most intimate experience, yet often hidden behind a wall of what Edmund Husserl [3] calls our *natural attitude*.

In this paper we also touch another, an even more veiled dimension of experience that we call *background experience* (explained further in the section 3) but most importantly we state that there is a gap between what we can easily consciously perceive and what we cannot – which, for the sake of clarity, we call *the crevice of awareness*. When trying to convey one's experience to another we stumble upon the next gap in the act of translating the experience into concepts, categories and linguistic forms. We believe that there is a gap between our perceived experience and its description, which we name *the fissure of description*. When trying to fill this fissure we believe the experience conveyed is flattened and reduced. The description produced in this effort then becomes the main building block of the bridge we are building from one side of the chasm and what we can offer to the conscious being reaching out from the other side. In this paper we compare this act of describing on one side and comprehending on another as a process of translation and that practicing experiential translation is the way to more valid and richer descriptions.

2 Experiential translation

Phenomenology, by origin a philosophical discipline, is trying to investigate concrete experiential phenomena and encourages detailed analysis of different aspects of consciousness. As such it has also been described as "a first-person description of 'what it is like' of experience" [4]. This subjective dimension 'as it is lived from the inside' is essential to consider in the field of scientific investigation of cognition and not be constrained merely to the data that can be observed and measured from the outside [5].

Claire Petitmengin [5] warns us that describing one's own subjective experience is not merely hard, but extremely difficult, mostly because turning our attention to our consciousness, and *a fortiori* describing it, requires inner effort and a specific kind of skillset. Her assumption is that a substantial proportion of our subjective experience unfolds below the threshold of consciousness. We question what her assumption presupposes - that our consciousness is something "in there" to be observed and we only need a better instrument to see further and better. We, on the other hand, are more inclined to view conscious phenomena as something co-created with and by the act of observation. In either case we believe that in the field of first-person research the two initial steps – becoming aware of our experience and then describing it - include two important gaps.

1. *The crevice of awareness* is the crack between what our "view from within" knows how to observe and what eludes our reflective thoughts. It denotes the difficulties of becoming aware of our background feelings and core dimensions of our experience.
2. *The fissure of description* is the gap between subjective observations of lived experience and descriptions of observed experience, which are most often verbal. This is perhaps at times even more frustrating, because in an instance when one has become aware of an experience, they must now try to find the right words and gestures to convey and verbalize a description that captures the nature of the subjective experience in question.

Subjective, or first-person research transfers to second-person research when we not only try to surmount *the fissure of description*, but we also convey this description to a researcher interested in exploring structures of lived experiences. Empirical or second-person research usually involves interviewing human participants about *their* experience. In the context of our paper, we call the interview method a rather wobbly bridge that tries to connect participants' lived experience with researcher's understanding *via* the participants' description of experience.

3. With this bridge we mark the third gap in the premise of empirical research of subjective experience – *the cranny of comprehension* – which spans between the second-person investigator and first-person report about the experience. It is a gap each researcher must fill and bridge when trying to comprehend and analyze the descriptive data on experience of others. We differentiate this cranny from the *chasm between two consciousnesses* because it is focused on the description and comprehension, not the entirety of another conscious experience.

We note that all three cracks are part of the greater *chasm between two consciousness*, which refers to the impossibility of experiencing as another being.

2.1 First-person translation

Jakob Boer [6] argues that the process of describing first-person experience is an act of experiential translation, with which we are inclined to very strongly agree. We believe that the act of describing subjective experience is an act of translation (latin *transfero*, "I convey", from prefix *trans-*, "across, beyond" and participle *latus* "borne, carried"). We will describe an example of a process of translating an ancient Greek text to a modern language. The underlaying assumption is that without an observer there is no meaning, and thus the nature and skill of the observer influence the source text immensely. Firstly, one must be able to see the Greek alphabet and know the symbols to perceive anything more than mere scribbles. Secondly, one must understand what a specific set of symbols denotes and relate to it a previously known meaning - one must understand the word. This step alone is complex and multidimensional, because one Greek word can have numerous possible translations and the meaning that stands out to the translator is tied to many factors, such as context and previous knowledge. Thirdly, one must understand the grammar and syntax to make sense of a sentence. With this we want to show how the meaning of a text is co-defined by the observer. The translator must then choose an accurate set of words in another language to convey his interpretation of the sentence. With this example we tried to show the complexity of our influences on what we perceive and how we leave a mark on both our perception and our description.

Experiential translation assumes that lived experience is in nature distinct from linguistic form, and that in the act of verbalizing we carry certain aspects across the gap between experience and description. In the act of translating our lived experiences into words, concepts, and categories we inherently imbue chosen meanings with our interpretation, which is perhaps inseparable from the way we become aware of our experience. We relate this intrinsic interpretation to *horizons of attending to experience*, as explained by Urban Kordeš and Ema Demšar [7], who argue that this co-defines experiential phenomena that end up being observed and reported. The *horizon* is the way in which we perceive, by which we mean co-create, our experience. This is enacted both when we try to observe and when we try to describe our experience.

2.2 Second-person translation

In the previous section we compared the process of describing one's lived experience to the process of translation. We continue with this analogy in the case of second-person research, when such translation is perchance more intuitive, because the 'input' – verbal report – comes in form of language. The researcher that receives the report proceeds with translating it in more than one way. First and foremost, the translation happens instantaneously, as it does every time we speak to another human being – we translate the words into our own known concepts and position them in our pre-existing field of knowledge.

Even more importantly, we aim to compare the subsequent process of analysing, categorizing and forming conclusions on the structure of experience to the process of translating, drawing attention once more to the notion that with translation always comes interpretation. As such we want to note and warn that becoming aware of your own *horizons of attending to experience* is a crucial step for every second-person researcher of

consciousness, which inherently makes them a first-person researcher as well.

3 Background experience

In this paper we turn our attention to a layer of experience which is, ironically, not in the focus of our attention but rather on the brink of it. William James [8] refers to this as the *fringe of consciousness.* To this fringe belong experiences that lack specific, sensory qualities, like the tip-of-the-tongue state (the intention to seek a missing word), feelings of knowing, familiarity and plausibility, intuitive judgments and numerous other conscious or quasi-conscious events that can be reported on with low sensory specificity.

What is it like aspect of those experience is hard to perceive and convey, but Petitmengin [9] describes certain internal gestures, which serve, in the language of our analogy, as bridges that enable us to become aware of the *source dimension* of our experience, which is usually *pre-reflective.* This unarticulated dimension is considered as core due to its ever-present nature, and because it is pre-conceptual and pre-discursive, it seems to be situated at the source of our thoughts. Although it constantly accompanies us, we need special circumstances to become aware of it and/or specific training in first-person observation.

In the realm of emotion, Antonio Damasio [10] calls a group of fleeting and hard-to-name feelings '*background feelings*', because they are not in the foreground of our mind, yet they help define our mental state and color our lives. We relate the foreground of our mind with the experiences on which we can easily focus our attention (such as thoughts, perceptions and loud emotions). Background feelings arise from background emotions, which are directed more internally than externally, but can nevertheless be observable to others in several ways: tone of our voice, prosody of our speech, the speed and design of our movements. According to Damasio, prominent background feelings include fatigue, energy, excitement, tension, relaxation, stability, instability, etc. The relation between background feelings and our drives and moods is intimate and close, but the relation between background feelings and consciousness is just as close, if not more. Matthew Ratcliffe [11] similarly develops the term *existential feeling* as a background which comprises the very sense of 'being' or 'reality' that attaches to world experiences. Specifically directed emotions presuppose this background, so regardless of the structure of such emotion, existential feelings are a more fundamental feature of world-experience. A few examples of such feelings are the feeling of being 'complete', 'unworthy', 'at home', 'abandoned' – all being descriptions of one's relationship with the world.

Hopefully we have now outlined the gap between our focal awareness and the experiences on the fringe of consciousness, where perhaps one of the keys to understanding our mind lies hidden. This gap was one of the points we tried to address in our recent project [12], in which we investigated the feelings of atmosphere with the presupposition that they are in the background of our mind. We will briefly present the context of our empirical investigations to use it as the reference point for our observations regarding the numerous gaps and blind spots of our methodological approach and epistemological premises.

4 Empirical context

In the aforementioned project, 'Unveiling of the Atmosphere – Etnophenomenological exploration of experiential background in relation to space', we aimed to investigate background experience which we have defined as feelings that weave the foundation on which foreground phenomena of consciousness unfold (such as emotions, thoughts and perceptions). We presupposed that experiences of atmosphere are by their nature affective, so we focused on the affective layer of experience. These feelings usually lack specific sensory attributes and are hard to pinpoint and often notice and/or name. We tried to capture and convey such background feelings with an empirical approach and a qualitative research design in which we combined approaches of first-person research such as Descriptive Experience Sampling Method (DES) [13], and ethnographical tools such as *in situ* diary entries. Our study was conducted in three phases, the first being the pilot study. We recruited three participants, previously trained in DES and first-person research, which we deemed important for a study that aims to research pre-reflective dimensions of experience.

Our participants reported about their experience in three ways: 1) through short written reports about randomly sampled moments during the day, 2) with diary entries on multiple occasions during the day of sampling, in which they situated randomly sampled moments in the context of their moods and behaviors, 3) in interview sessions in which we explored and expanded previous two types of data. The aim was to map our participants' affective experiential landscapes and to contextualize their experiences with information about their activities, environment and social interactions. We have analyzed the data according to the principles of qualitative analysis [14], which produced a list of experiential categories divided into two (vaguely distinct yet obviously separate) groups of *foreground* and *background affective experience.* In the background we situated categories such as *background mood*, *ambient atmosphere* and *deep atmosphere*.

1. *Background mood* is felt as all-encompassing and includes different ways of receiving, creating and experiencing foreground experiences (affects, thoughts and percepts), which we call different attitudes. We found three subcategories of background mood: open, closed and numb.
2. *Ambient atmosphere* includes experiences that are not clear and separate, but pervasive and ubiquitous. It represents feelings, which we feel originate from the world, and we are entangled with it either as their co-creator or merely as an observer.
3. *Deep atmosphere* includes experiences that we feel as deeply our own and private. Imprint of *deep atmosphere* marks the way of foreground affects as well as other background feelings. Phenomenologically it is harder to reach and observe, as it usually changes its character less or more slowly. When captured, we observed two distinct subcategories of feelings: *deep perturbation* and *deep unconcern*, the former connected to the feelings of danger and the latter to the feelings of safety.

5 Observational interstices

In this section we aim to address some methodological cracks and to note our observations from our research project on background feelings [12].

5.1 Becoming aware

In our study participants were prompted with a signal which conveyed to them that they should observe and report on their experience of the moment right before the signal. During the interviews they oftentimes reported that after the signal there was a brief state of feeling 'blank', as if the moment before the signal was empty and void of any experience whatsoever. But this feeling soon passed, and they started to remember and find words to describe the moment before the signal. We interpret this feeling of 'blankness' as a type of gap between being immersed in the *natural attitude* [3] and adapting the *phenomenological attitude*. To put it differently – we believe that the act of *epoché* is both and act of opening a gap and of bridging it. We argue that each time we try to bracket our trust in the objectivity of the world, we reveal and/or create a crack in the fluidity and continuity of the flow of our conscious experience. This means that when we change the nature of our awareness, we experience a moment of emptiness. To explain we will compare our awareness with the grip of our hand. When we hold on to one object, let's say a glass, we are gripping something and sensing specific qualities. When we want to switch to a different object, we must first release the glass and be (and thus feel) empty at least for a moment so that we can grip (experience) something else.

5.2 Observing experiential background

As mentioned in the section 2, we tried to observe and capture background feelings with the intention of mapping participants' experiential landscapes of affects. Based on the literature and preliminary observations we presupposed that background feelings change less frequently, which is one of the reasons they are more elusive and harder to notice, as opposed to the foreground experiences which change from moment to moment and require most of our attention.

Our findings support our claim that one way to notice the ever present is by gaps in continuity. Such a way requires regular first-person observation, optimally supported by a second-person approach (dialogue). Noting one's experience often over a longer period can bring to light changes that unravel slowly. To explain this with a more concrete and visual analogy – when a person on a diet is losing weight (if they are doing it in a healthy and sustainable way) they won't see any progress from day to day, but if they observe and measure themselves methodically throughout the whole year, they can notice a vast difference from their starting point.

5.3 Describing lived experience

Tying to the conclusion of the previous paragraph is a very concrete observation based on our research methodology. As described in section 2, we gathered reports on our participants' experience in three ways (short notes on experience of moments during the day, diary entries and interview insights). What we noticed is that often in the descriptions of a singular moment there was a lot of emphasis on the foreground experiences and less so on the background feelings. When participants weaved those moments in the experiential timeline of their whole day (and in the interviews of their whole week) more background feelings came into light – even in the moments which we had detailed descriptions of. We would like to note that minimising the effect of memory on reports is important, but that sometimes in this effort we miss something because it is 'right under our nose'.

6 Conclusion

Delving into the field of empirical phenomenology is a courageous act, because there are few, if any, clear and firm climbing holds. We understand why scientific discourse steers toward replicable and third-person tested approaches, yet we believe that exploration of lived experienced cannot (at least as of yet) be accessed any other way than through subjective observation first. And even if the act of bridging the subjective with intersubjective is full of gaps and other cracks, we stay positive that the descriptions and interpretations produced in this process lead to better understanding of how to approach empirical research of subjective experience. In the analogy of translation as the act of describing one's own experience, we aim to paint the following picture. In the gaps that lurk amid experiencing, being aware and describing, many pieces of the original experience are most likely lost in translation. Yet by persistently and methodically carrying over the remaining pieces created by this process we are building better and more reliable bridges.

Abstract

In this paper, we draw parallels between existing research practices and attempt to piece them together to propose a more wholesome approach in conducting experience sampling research. We consider Experience Sampling Methods (ESM) as valuable tools for studying experience, but they come with challenges, of which we address the participant burden as one of the most significant ones. We think that integrating practices from Personal Science (PS) and Citizen Science (CS), grounded in empirical phenomenology, can help address this challenge. By considering participants as co-researchers and actively engaging them in the research and community, we aim to enhance their motivation and improve the quality of the research data. We illustrate this approach through the pilot project Luna in which we explore lived experiences throughout the menstrual cycle using the ESM mobile application "Curious". This integrative method facilitates a reciprocal knowledge exchange between researchers and co-researchers, which deepens the process of self-exploration and holds a great potential to advance scientific research on experience.

Keywords

Experience sampling methods, citizen science, personal science, empirical phenomenology

1 Introduction

Scientific research into experience is a rapidly growing field. Some researchers and philosophers point out that a core problem within our current scientific worldview is the overlooked experience research [1]. New methods and tools for researching experience are being developed, among which are Experience Sampling Methods (ESM). ESM are intensive longitudinal approaches to collecting experiential and contextual data using structured diary self-report techniques [2]. Due to numerous advantages, especially ecological validity and the reduction of recall bias, ESM has spread to various research fields through the use of mass technology, mostly mobile applications [3]. Based on numerous studies [4, 5, 6] that have used ESM to investigate experiential phenomena in the past few decades, weaknesses of these methods have been identified [7].

We present ESM and the challenges inherent in ESM research, particularly participant burden. By exploring the interest in personal exploration within Personal Science and emphasising the importance of community building in Citizen Science, we attempt to tie these practices together using the concept of a methodological turn from empirical phenomenology [8]. We believe that the challenge of participant burden, which we see as under addressed but highly disruptive in ESM scientific inquiry, can be tackled through this integration of different research practices. We illustrate this approach with our pilot study, Luna.

2 Experience sampling research

We consider Experience Sampling Methods (ESM) as an umbrella term for the research in which participants gather samples of their experiences as they unfold in their life [9]. Typically, we prompt participants at random times to answer questions or to describe their experience of the moment just before they heard the beep [10]. This way we are able to minimise recall bias [7] and are able to sample dimensions of experiential states which are nearly impossible to recall later, especially in detail (e.g., the momentary content of our thoughts). These methods are also highly ecologically valid, since we are sampling experience as it unfolds naturally in people's everyday lives. Participants would receive the prompts several times per day for a longer period of time (e.g., two weeks). These repeated measures enable us to track patterns and changes in individual experiences across time and different contexts [7, 10]. Nowadays we use mobile applications on participants' personal smartphones which makes the data collection process in comparison to pen and paper much more reliable and less burdensome [11].

2.1 Challenges in ESM

ESM research is still loosely defined without a rigorous framework and we are yet to develop appropriate methodological approaches for improvements [9]. A significant challenge in ESM research is participant burden. Collecting frequent, real-time data in everyday life activities puts great demands on participants who need to albeit shortly interrupt their activity to report on their momentary experiential state [3]. These repeated measures over time might affect participants' attitudes towards the research and result in reduced compliance, careless responding and participants' attrition [12]. We should also evaluate this burden from an ethical perspective, ensuring that

benefits outweigh the burden, especially if there is a consideration of affecting participants' well-being [13].

2.2 Existing recommendations for addressing the challenges in ESM

To mitigate this burden, researchers are working on questionnaire optimisation, making them as brief and focused as possible by prioritising essential questions and using clear and concise language [9]. The trade-off between data richness and burden on participants is also mitigated with lowering the sampling frequency [12]. By introducing the personalised scheduling for participants we avoid interrupting them in the situations in which they are unable to respond and would likely react negatively to prompts being delivered in that time [3]. Albeit we should then revise random sampling and account for the introduced bias (e.g., we could supplement the data with retrospective daily reports).

However, a key factor for successful ESM research is participants' motivation [3, 7]. It is better sustained by considering the necessary technical recommendations, but researchers should also give attention to fostering the research interest and social dynamics. Researchers should engage participants who already have interest in the research topic and therefore an intrinsic motivation to learn more on it [3]. They should also provide a sufficient training period in which participants gain the necessary knowledge and skills in order to sample the experience [7]. It is important to establish a rapport with participants and to foster a research alliance throughout the study [2]. It is suggested to provide rich feedback to participants during and at the end of the study which can also be presented as non-monetary compensation [3].

3 Personal science and interest for self-exploration

Technological advancement played a great role in a growing number of ESM studies as well as in an uptake of self-tracking practices for exploration of oneself [14, 15, 16]. The umbrella term for self-tracking practice and communities has been formed under Personal Science (PS) [17]. These individuals and groups pursue their own personal research questions using empirical methods in an iterative process of questioning, designing, observing, reasoning, and discovering which presents itself as an opportunity to scientifically expand on PS. Even though we can draw many parallels between self-tracking and scientific inquiry the question remains to what extent PS can be scientifically interesting [18]. Considering the growing interest in PS activities it seems important to address these practices, especially in new self-trackers. They often experience difficulties in making sense of their self-tracking process in interpreting their data, formulating and refining their research questions, and designing their research process [19, 20]. It would be beneficial for them to receive support that provides at least an initial establishment of their research or engaging them in a more systematic way. Lack of scientific rigour was also reported by researchers in tools used for self-tracking which can potentially mislead self-trackers and give them false ideas of phenomena they explore [21, 22]. Hence, we believe this is an excellent opportunity for the science community to engage in this already widespread phenomenon. Individuals and groups who already possess deep interest in self-exploration can potentially become great co-researchers by which they would gain support in their own exploration as well as make the scientific contribution.

4 Community in Citizen science

Citizen Science (CS) is recognized as one of the eight pillars of Open Science, playing an integral role in democratising scientific knowledge and practices [23]. It significantly bridges the gap between the scientific community and society through the idea of doing science and not merely reacting to it [24]. Due to the heterogeneity of CS projects in terms of scale, objectives, and levels of citizen scientist involvement, it is challenging to provide a universal definition [25]. However, common to all CS projects is to actively involve non-professionals in scientific research at different levels of participation [26]. In a broad sense citizen scientists perform tasks that would be otherwise done by scientists [27] or would not be possible to do without their involvement.

To achieve reciprocity between science and society in CS projects in which the bidirectional knowledge exchange facilitates benefits in both [28], significant time and resources need to be invested to establish the conditions for project activities to run [29]. Since citizen scientists are typically lay people without formal training in scientific research, appropriate training and support are essential to equip them with necessary skills and knowledge [30]. We know citizen scientists engage in the projects upon different motivation factors. We can observe the intrinsic factors, such as gaining fulfilment, enjoying the activities or being altruistic and extrinsic factors, such as building social interactions, gaining on reputation or status and expecting future returns [31]. Therefore, sustaining motivation and engagement requires more than just training. CS practitioners should establish good relationships with citizen scientists and a continuous communication as well as the conditions for citizen scientists to meet and work with each other. We argue that essential to the project's success is building a strong community. Utilising online community spaces, social media, organising workshops and training as well as local meetups, collaborative and other social activities facilitate community building. Strong community in exchange encourages participation, promotes knowledge sharing, foster collaboration and builds on sustainability of the project [32, 33].

5 Bridging ESM, PS and CS with empirical phenomenology

The key to integrating the practices of Citizen science, Personal science, and Experience Sampling research lies in the concept of a methodological turn developed in the field of empirical phenomenology [8]. In experience research, the observed is the observer, meaning that the only access to the phenomena of interest is through the observer's subjective experience. If the observer does not adopt an attitude of curious exploration and engage in epoché, meaning bracketing the natural attitude, the judgments, interpretations, and explanations of their experience, we cannot obtain data on the genuine experience as it unfolds in life. This notion is rooted in phenomenological reduction, a

method of research into experience developed by Edmund Husserl [34]. Experience Sampling has been used to study subjective experiences in real-time contexts, but integrating it with phenomenological reduction enhances the depth of data on lived experiences [35]. Therefore, it is necessary to consider our participants as co-researchers. This attitude allows us to engage them in a way that fosters their interest in the research question which facilitates the methodological turn where the research question becomes in a sense their own and they become researchers of their own experience. While providing the support and means for investigation, it is important to give co-researchers the freedom to explore the research question and their experience in a way that is meaningful to them, and to encourage critical discussion. By opening up the space for co-creation of the research design and enabling co-researchers to actively contribute their findings, we facilitate a deeper reciprocity of knowledge transfer.

6 The pilot study "Luna"

Citizen science project Luna aims to explore the lived experiences of menstrual cycles and their impact on everyday well-being. We use a diary method for daily reports and Experience Sampling Methodology (ESM) to track experiences throughout the menstrual cycle with the use of the ESM mobile application Curious (about) consciousness or Curious in short.

We adopted the iterative co-creation approach to develop our research, combining the principles of ESM research, CS projects, PS and empirical phenomenology. This makes our research process flexible in a way that the research design is being updated in an iterative collaborative manner. We engage co-researchers in the design and assessments of data collection procedure and questionnaires, data interpretation as well as analysis. By encouraging them to develop their own research questions which are relevant to their own experience we promote their personal endeavor in the research. They are also involved in other project activities, such as sharing results and designing the project visual identity. We organise different learning and sharing community activities. In the training workshops we introduced them to the principles of observing ones' own experience, how to bracket the natural attitude and report on the pristine inner experience. On our online community space as well as in the organised meetups we share feedback on the research and their participation, engage them in the conversation on the research topic related questions and encourage them to share their own feedback. They are also invited to share any findings they have along the way in the mobile application. The Curious app is designed in a way to support co-researchers in their data interpretation by providing them with simple visualisations of their gathered data which they are able to filter, compare and reflect on. Our aim in the research is two-fold. It is driven to answer the research questions on phenomenology throughout the menstrual cycle as well as to equip co-researchers with methods and tools to research their experiential landscape and gather self-knowledge. Project tries to go beyond research by also opening up the data driven discussion on possible systemic or social solutions to consider the physiological and phenomenological cyclic nature of people with menstrual cycles. This also presents a motivational factor for some co-researchers who would like to see positive (societal) changes in regard to this phenomenon.

7 Conclusion

We argue that a large number of research questions in ESM research could be better investigated if research projects adopt the CS framework with an emphasis on community building, account for the interest and practice of PS, and use the principles of experience investigation from empirical phenomenology. The challenge of participant burden in ESM research is then mitigated by creating conditions for co-researchers to be involved in personally meaningful activities, which in return provide a higher level of data validity. Even though considerable resources are needed to establish these kinds of project communities, we believe they have the potential to be more sustainable. From CS, we know that citizen scientists develop a sense of community, which encourages them to remain active in science after the initial project ends [36, 37]. This interdisciplinary integration of different research practices enhances the value of our investigations and creates more impactful and sustainable research projects that benefit both the scientific community, involved co-researchers and the society.

PREDGOVOR

Tehnologije, ki se ukvarjajo s podatki so močno napredovale. Iz prve faze, kjer je šlo predvsem za shranjevanje podatkov in kako do njih učinkovito dostopati, se je razvila industrija za izdelavo orodij za delo s podatkovnimi bazami in velikimi količinami podatkov, prišlo je do standardizacije procesov, povpraševalnih jezikov. Ko shranjevanje podatkov ni bil več poseben problem, se je pojavila potreba po bolj urejenih podatkovnih bazah, ki bi služile ne le transakcijskem procesiranju ampak tudi analitskim vpogledom v podatke. Pri avtomatski analizi podatkov sistem sam pove, kaj bi utegnilo biti zanimivo za uporabnika – to prinašajo tehnike odkrivanja znanja v podatkih (knowledge discovery and data mining), ki iz obstoječih podatkov skušajo pridobiti novo znanje in tako uporabniku nudijo novo razumevanje dogajanj zajetih v podatkih. Slovenska KDD konferenca SiKDD, pokriva vsebine, ki se ukvarjajo z analizo podatkov in odkrivanjem znanja v podatkih: pristope, orodja, probleme in rešitve.

FOREWORD

Data driven technologies have significantly progressed. The first phases were mainly focused on storing and efficiently accessing the data, resulted in the development of industry tools for managing large databases, related standards, supporting querying languages, etc. After the initial period, when the data storage was not a primary problem anymore, the development progressed towards analytical functionalities on how to extract added value from the data; i.e., databases started supporting not only transactions but also analytical processing of the data. In automatic data analysis, the system itself tells what might be interesting for the user - this is brought about by knowledge discovery and data mining techniques, which try to obtain new knowledge from existing data and thus provide the user with a new understanding of the events covered in the data. The Slovenian KDD conference SiKDD covers topics dealing with data analysis and discovering knowledge in data: approaches, tools, problems and solutions.

Abstract

Knowledge graphs have traditionally required the use of specific query languages, such as SPARQL, to retrieve relevant data. In this paper, we present a system capable of performing natural language queries on knowledge graphs by leveraging retrieval-augmented generation (RAG) and large language models (LLMs). Our system can ingest large knowledge graphs and answer queries using two approaches: first, by utilizing LLMs to extract information directly from subgraphs; and second, by generating SPARQL queries with LLMs and using the results to inform further inference, such as counting the number of items.

Keywords

knowledge graph, semantic inference, Industry 4.0, LLM, RAG

1 Introduction

In the context of Industry 4.0, knowledge graphs play a crucial role in mapping and describing the entire production vertical, from supply and demand dynamics to intricate details within the production process. This includes the configuration of shop floors, production lines, machines, and data setups, extending even to specific datasets generated during operations. Knowledge graphs can also include relevant information about the tools required for particular processes, as well as details about personnel, including their skills and roles.

A key standard for representing such data within the Industry 4.0 initiative is the Asset Administration Shell (AAS) [3], which provides a logical representation for a factory asset (can also be a piece of software, etc.). By adopting AAS, industries can ensure interoperability and standardization, enabling more efficient data exchange and integration across various systems, ultimately enhancing the agility and responsiveness of manufacturing processes.

Querying knowledge graphs can be a challenging task for end users, as it often requires expertise in specialized query languages such as SPARQL [8] — a skill that is not widely known among non-experts. Working with SPARQL SELECT queries remains a challenge also for LLMs, with performance varying significantly depending on the specific model and task complexity. While the leading LLMs can reliably address basic syntax errors, generating semantically accurate SPARQL SELECT queries remains difficult in many cases [10]. Similar work has been done on interaction with databases, however even with SQL query generation the results of GPT-4 are still far behind human ability (approx. 55% execution accuracy) [9].

To overcome these challenges, we propose a system that enables users to interact with knowledge graphs through natural language queries. The system leverages LLMs' capabilities to interpret knowledge graphs while compensating for their limited ability to generate fully syntactically and semantically correct SPARQL queries. Proposed system, depicted in Figure 1, leverages large language models (LLMs) [11] to process natural language inputs and provide responses in natural language. Our approach integrates retrieval-augmented generation (RAG) techniques alongside the automatic generation of SPARQL queries based on natural language input [2].

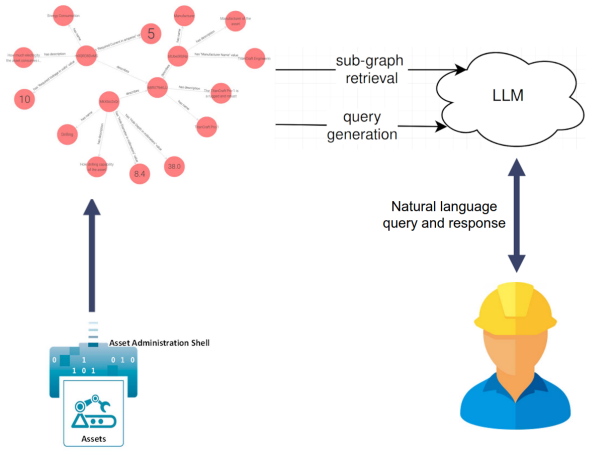

Figure 1: Intended usage of the system: AAS instances are converted into a knowledge graph, enabling natural language queries by the user.

By doing so, our system not only simplifies the querying process but also ensures that the responses are accurate and contextually relevant, making knowledge graphs more accessible and usable for a broader range of users. Additionally, the use of LLMs in combination with SPARQL querying enables the system to handle complex tasks, including those that require logical reasoning, aggregation, or interpretation of data, thus enhancing its utility in real-world applications. For example, our system is able to answer queries such as: "Give me all machines that are capable of drilling a hole with 2cm perimeter".

Finally, question answering with the help of knowledge graphs and language models has been tackled before [16], however, the development of retrieval-augmented generation (RAG) systems has seen significant growth recently. In 2024, several preprints have emerged showcasing the application of the RAG approach to knowledge graphs [12, 13, 14]. This paper contributes to this rapidly evolving field by presenting our own advancements and findings.

2 Data

This study uses a generated dataset representing a hypothetical factory with various machine models, designed to test the capabilities of the developed application. The work is part of the Smart Manufacturing pilot in the EU-funded HumAIne project [7], with the aim of eventually using real-world data from participating factories.

The mock factory includes models of "DRILLERS", "CIRCLE CUTTERS", and "CIRCULAR SAWS", each with unique names, manufacturers, and descriptions. These models are represented using AASs with relevant submodels for energy consumption, manufacturer details, and operation-specific parameters like hole diameter or depth of cut.

We created AASs for 7 drilling machine models, 7 circle cutter models, and 10 circular saw models, along with 1,000 machine instances randomly assigned to these models. Numerical values and availability were populated randomly for testing, reflecting potential real-world variations.

The initial step after acquiring AAS data is to convert it into a knowledge graph. This process involves transforming JSON-serialized AASs into RDF triples, which represent the semantic information of the data. Once the RDF triples are generated, they are stored in a GraphDB[1] repository. To enable semantic data retrieval, we employ a connector that interfaces with the ChatGPT Retrieval Plugin[2], which operates alongside the server application. When new triples are added to the GraphDB repository, the connector triggers the plugin to generate vector embeddings of the text representations of the new nodes. These embeddings are created using a language model and are stored in a separate vector database. The ChatGPT Retrieval Plugin enables interacte to a selection of different vector databases, in our case we employed the Milvus vector database. The system is also designed to maintain consistency; if any triples are removed from the GraphDB repository, the corresponding vector embeddings are automatically deleted from the vector database.

3 Methodology

The system architecture is illustrated in Figure 2. The user interacts with the system through a client application, developed using ReactJS, which serves as the graphical user interface (GUI). This client application communicates with the system's middleware, which is built on the Flask framework. Users have the capability to upload AAS data to construct and enhance the knowledge graph, as well as to issue natural language queries.

The middleware acts as the core of the system, facilitating communication between the client application, the knowledge graph stored in a GraphDB database, and OpenAI's GPT models. The AAS data uploaded by the user is first converted into RDF triples and then stored in the GraphDB repository. The Flask-based middleware also integrates with the ChatGPT Retrieval Plugin, which is responsible for generating vector embeddings of the knowledge graph nodes using OpenAI's `text-embedding-ada-002` model.

These vector embeddings are stored in the Milvus vector database [15]. The ChatGPT Retrieval Plugin allows the system to efficiently retrieve the most relevant embeddings in response to user queries, ensuring that the system can provide accurate and contextually appropriate answers. Additionally, the middleware leverages LlamaIndex[3] to manage sub-graph retrieval and query generation, which are essential for responding to complex queries by the user.

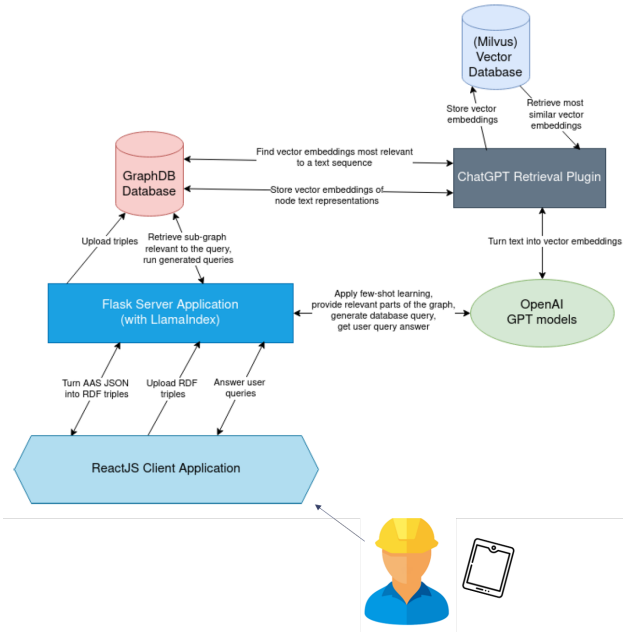

Figure 2: System architecture for retrieval augmented generation with knowledge graphs in Industry 4.0.

In summary, the architecture is designed to streamline the process of building a knowledge graph from AAS data and enables users to query this graph with retrieval-augmented generation (RAG) using natural language, with the system handling the complexities of data storage, retrieval, and natural language processing in the background.

The sequence diagram in Figure 3 illustrates the interaction between system components during query processing. Our system enables two distinct approaches to handle natural language queries, often combining both to generate a comprehensive answer for the user.

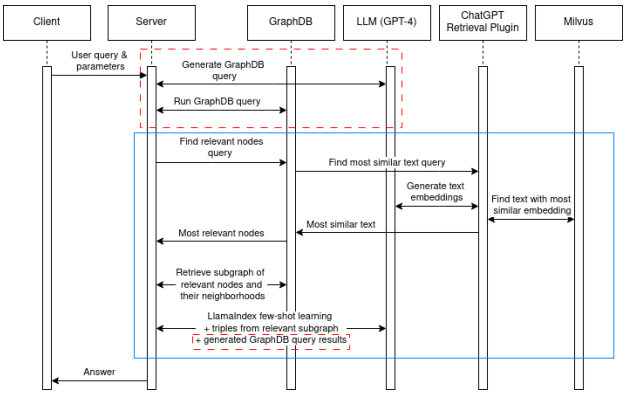

Figure 3: Sequence diagram of different approaches for data extraction. The blue box represents the RAG approach and the red box represents the SPARQL query generation approach. Note that RAG approach utilizes results from SPARQL queries on the knowledge graph.

[1] https://graphdb.ontotext.com/
[2] https://github.com/openai/chatgpt-retrieval-plugin
[3] https://www.llamaindex.ai/

The first approach utilizes a Retrieval-Augmented Generation (RAG) method. Upon receiving a query, the system analyzes the query to identify relevant concepts and generates vector embeddings for these concepts [5]. These embeddings are then matched against the knowledge graph stored in GraphDB to find the most relevant nodes. Once the relevant nodes are identified, a naive neighborhood expansion is performed, capturing additional related nodes to ensure a more complete context. The search is parameterized using parameters: scope, how many nodes from the graph to retrieve; breadth, from how many relevant nodes to start the neighborhood expansion; score weight, how many more nodes are visited from the identified relevant nodes that are deemed more relevant using embedding similarity. This subgraph, along with a few examples for context, is then fed into the Large Language Model (LLM) using a few-shot [1] learning technique to generate a response [4]. The LlamaIndex framework provides a general context query for turning triples into natural language. This method is particularly effective for queries requiring contextual understanding and extraction of complex information from the knowledge graph.

The second approach involves generating a SPARQL query based on the natural language query and the ontology used within the knowledge graph. The system attempts to execute this SPARQL query in the GraphDB database. If the query runs successfully, the resulting data is passed to the LLM to formulate the final answer. This approach is especially beneficial for tasks that involve counting instances or performing specific data aggregation operations, where LLMs alone might struggle. This approach benefits from the first approach as it can use it as backup or to enrich the SPARQL query results with additional context.

4 Results

To thoroughly evaluate the system, we employed three different evaluations: (a) assessing the accuracy of data retrieval based on query parameters (not using query generation), (b) evaluating the system's ability to correctly fetch the number of instances (testing query generation), and (c) conducting a manual assessment of most relevant user queries.

4.1 Accuracy of Data Retrieval

The first approach involved testing the system's ability to accurately retrieve data that met specific query conditions without employing SPARQL query generation. We focused on queries where the user requested a list of machines of a particular type with a voltage requirement less than or equal to a specified value. An example query would be: "Return all drilling machines that consume at most 4 volts and specify their consumption."

We conducted these tests on three types of machines: "drilling machines", "circle cutters", and "circular saws". The voltage values specified in the queries ranged from 0 to 10 volts, inclusive. The evaluation was designed to measure how accurately the system could identify and return the correct set of machines based on these voltage constraints.

For these tests, the following parameters were used (scope: 100, breadth: 1000, score weight: 100, model: `gpt-4-1106-preview`, query generation strategy: **disabled**).

The system's performance was assessed by comparing the retrieved data against the expected results, specifically checking the number of machines that met the voltage criteria and identifying any errors, such as incorrect voltage values or unnecessary machine retrievals. Results are depicted in Figures 4 and 5.

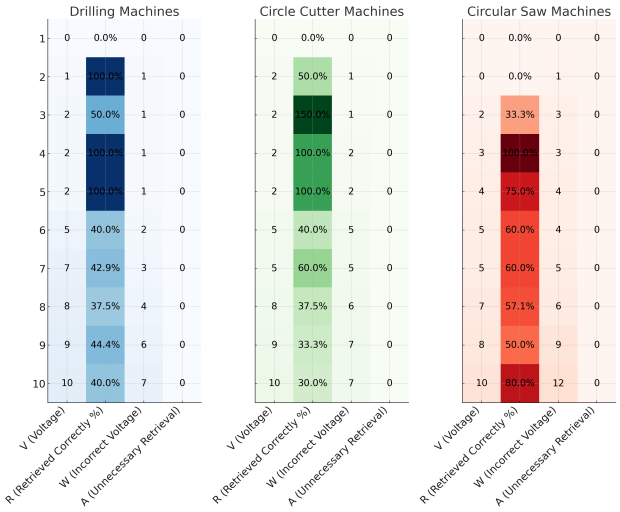

Figure 4: Performance of the system by the type of the machine and query.

In Figure 4, each table contains four columns: "V" (voltage specified in the query), "R" (percentage of correctly retrieved machines), "W" (number of machines with incorrect voltage), and "A" (number of unnecessary machine retrievals). Figure 5 summarizes the results: "Fully Correct Answers" shows the percentage of queries that returned all requested information without errors; "Share of Expected Information Found" indicates the proportion of requested information retrieved; and "Share of Incorrectly Displayed Voltages" represents the percentage of retrieved voltages that were incorrect.

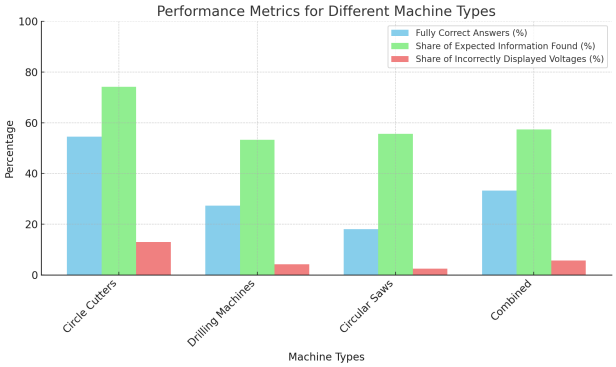

Figure 5: Combined performance.

The results show that sometimes the LLM would incorrectly generate a different voltage requirement for a machine, making it appear to satisfy the query conditions. However, the retrieved machines were always of the correct type. For example, a query like "Name all drilling machines and specify their voltage requirements" correctly retrieves all machines with the right specifications, suggesting the issue may lie with the LLM rather than the knowledge retrieval process.

To address this, users can try adjusting query parameters or rewording the query to verify the information's accuracy. If this

type of query is crucial, incorporating voltage-specific queries into the query generation strategy could improve reliability, although the LLM may struggle with large lists due to its context window limitations. As shown in Figure 5, these types of queries often do not reliably provide all requested information in one answer, so users should run multiple queries to increase the likelihood of retrieving all necessary data.

4.2 Instance Fetching Accuracy

In these tests, we tested query generation strategy. The following parameters were used (scope: 100, breadth: 1000, score weight: 100, model: `gpt-4-1106-preview`, query generation strategy: **enabled**).

The queries asked for the number of available instances for selected machine models, such as "Get the number of available [name of the machine 1], [name of the machine 2] machine instances. Specify the number for each machine type separately.". The query format was picked such that the LLM will benefit from query generation (availability property is specified in the schema supplied for query generation).

A total of 100 queries were run, with 10 queries for each number of specified machine models (ranging from 1 to 10 models). The share of fully correct answers for each query type was between 80 and 100%. The overall accuracy was 96%. This supports our hypothesis that the query generation strategy provides more accurate answers for slightly more complex queries.

4.3 Manual Evaluation of Example Queries

This evaluation was initially performed to identify several shortcomings in our methodologies as mentioned in the previous subsections. By manually evaluating specific queries relevant to end users, we were able to partially address these issues and fine-tune parameters to achieve more accurate results. For instance, while the system's initial results were often incomplete (e. g., query did not return all the machines satisfying certain criteria), increasing the breadth parameter to include a larger subgraph and allowing LLMs to traverse a broader neighborhood improved the results. Additionally, we demonstrated that subgraph retrieval and query generation can complement each other, further enhancing overall performance. All the results are commented in detail in [6].

5 Conclusions

In this paper, we presented a system that bridges the gap between natural language processing and querying knowledge graphs, specifically within the context of Industry 4.0. By leveraging large language models (LLMs) and retrieval-augmented generation (RAG), our system allows users to interact with complex knowledge graphs using natural language queries, thereby simplifying access to detailed manufacturing data.

Our evaluation demonstrated the usability of our system, however with the integration of LLMs for natural language understanding, some challenges remain. These include occasional inaccuracies in data retrieval and the LLM's limited ability to handle large datasets or specific queries. By adjusting subgraph retrieval parameters such as breadth and scope, and by combining it with SPARQL query generation, we were able to significantly enhance the system's accuracy and reliability.

This work highlights the potential of combining knowledge graphs with LLMs to create more intuitive and effective query systems in industrial environments. Future improvements could focus on refining query strategies and further optimizing the balance between subgraph retrieval and SPARQL generation to ensure even more robust and comprehensive query handling.

Abstract

This paper presents a comparative evaluation of three distinct categories of models applied to groundwater level data: traditional batch learning methods, time series deep learning methods, and time series foundation models. By enriching the water level data with weather-related features, we significantly improved the effectiveness of simpler models. The results demonstrate that, despite their state-of-the-art performance on univariate datasets and the corresponding publicity, advanced models without contextual feature support are still surpassed by traditional methods trained on enriched datasets.

Keywords

groundwater level prediction, time series forecasting, deep learning, foundation models, contextual data

1 Introduction

Accurate water level prediction is crucial for mitigating the impacts of climate change on water resources. By forecasting water levels, we can better prepare for potential floods and droughts, and more effectively manage our water supplies. However, predicting water levels presents a significant challenge due to the dynamic nature of the data. As climate change leads to prolonged droughts and increasingly erratic precipitation patterns, the need for reliable forecasting methods becomes even more important [2].

In this paper, we aim to compare the performance of various models in forecasting groundwater levels. Specifically, we focus on the differences between traditional batch learning methods that utilize relevant contextual data and newer univariate time series deep learning and foundation models.

The main contributions of this paper are:

- A comparative analysis of the performance of traditional batch learning methods against state-of-the-art time series deep learning techniques and time series foundation models, particularly in the context of feature vectors enriched with relevant contextual data.
- The application of time series foundation models and deep learning methods to the domain of groundwater level forecasting.

The groundwater dataset used in this study has previously been employed for predictive modeling with traditional batch learning methods [9], where extensive feature engineering was also performed. Our work builds upon and extends this earlier research by incorporating a different set of models.

2 Methods

In our experiments, we employed three categories of methods: traditional batch learning techniques, time series deep learning models, and time series foundation models.

2.1 Traditional Batch Learning Methods

In the context of data-driven modelling of environmental issues, traditional batch learning methods have historically demonstrated significant success [5]. In this study, we employed linear regression alongside two tree-based approaches: random forest and gradient boosting [7] as baselines to evaluate whether the newer, more prominent techniques, which have recently gathered a considerable amount of attention, can perform competitively in this specific setting.

All of the chosen batch learning techniques are regression-based and are valued for their simplicity, speed, and ease of use. However, they often lack the complexity necessary to fully capture intricate patterns in the data. To mitigate this limitation, we incorporated contextual features, such as weather data and forecasts (e.g., precipitation, cloud cover, temperature). While the data fusion problem is solved [8], this approach raises concerns about the availability and relevance of the contextual data.

2.2 Time Series Deep Learning Methods

Time series deep learning models are explicitly designed for forecasting time-dependent data. In our study, we employed N-BEATS [12] and PatchTST [10], both of which have architectures tailored to capture trends and seasonalities inherent in time series data. Despite their advanced capabilities, these models have drawbacks, including longer training and inference times, the necessity for extensive hyperparameter tuning to achieve optimal performance, and limited support for incorporating additional features. Although certain models support multivariate time series, they were not utilized in our experiments.

2.3 Time Series Foundation Models

While deep learning methods require separate training and prediction phases, time series foundation models aim to eliminate the training step. Inspired by large language models, these models are pretrained on extensive time series datasets, enabling zero-shot predictions on new time series without additional training. We used CHRONOS [1], an open source foundation model. The advantages of this approach include ease of use with minimal parameter adjustments and no need for training. However, similar to deep learning models, they lack support for multivariate time series.

Several studies have already evaluated the performance of various deep learning and foundation models for time series forecasting [1] [13]. However, this research extends the application of these forecasting models to groundwater level data, therefore contributing to the better understanding of their effectiveness in this domain.

3 Experiment Setting

The experiments were conducted on a dataset of groundwater levels in Slovenia. Due to the cumulative nature of water levels and to facilitate comparison with the original study [9], predictions were made on daily changes in water levels rather than on absolute values.

3.1 Dataset

The groundwater dataset is a subset of the larger dataset used in the study [9]. It consists of groundwater level measurements taken daily from multiple stations across Slovenia. To apply traditional batch learning methods, we enriched the dataset with weather data, associating each water measurement station with the nearest weather station. Due to the availability of weather data, only data from the years 2010 to 2017 was included in our study. For consistency and ease of comparison with previous study [9], we focused on data from two water measurement stations located in Ljubljana.

In traditional batch learning within the environmental domain, it is essential to not only use the raw data but also to engineer relevant features. Initially, we removed the pressure and dew point features, as they were either unrelated to the target variable or highly correlated with other features [9]. We then created additional features by shifting the data from 1 to 10 days, making historical values available, and by computing the averages of features over a 2- to 10-day window. This process resulted in approximately 2,000 features. Given the excessive number of features, which could degrade model performance, we employed a feature selection algorithm to identify the most informative subset.

We used a genetic feature selection algorithm from scikit-learn, evaluated on 365-day part of training dataset, with the maximum number of features set to 40. The algorithm was executed separately for each model, focusing on one station and a prediction horizon of three days, resulting in distinct feature vectors. Subsequently, weather forecast features with longer offsets were manually added to the selected feature set.

3.2 Evaluation Metrics

The dataset was split into a training set (approx. 2,500 days), a validation set (100 days), and a test set (365 days) for model evaluation. Model performance was evaluated using the R^2 score, averaged across all tested stations. Although alternative metrics such as root-mean-squared error (RMSE), and mean absolute percentage error (MAPE) were considered, they, for this dataset, produce results that are closely related to the R^2. This metric was selected due to its robustness against variations in data offset and amplitude, and for direct comparability with the results in the original study [9]. The R^2 score is defined as:

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2},$$

where y_i is the i-th true value, $\hat{y}_i$ is the i-th predicted value and $\bar{y}$ is the average of true values.

3.3 Baseline Methods

The primary objective of our research was to compare the performance of traditional batch learning methods, enriched with relevant contextual features, against that of modern deep learning techniques and foundation models for time series forecasting. Therefore, we selected linear regression, random forest regressor, and gradient boosting regressor as our baseline methods. These models were previously applied to the groundwater dataset [9], necessitating a reproduction of the results as a benchmark.

3.4 Implementation Details

The prediction pipelines varied slightly between the different types of models:

- For **CHRONOS**, we utilized the dataset without weather features, as it only supports univariate time series. Since no hyperparameter tuning was required, the data was divided into training and test sets, omitting the validation set. The model generated the predictions directly from the water level data. We used the chronos-t5-large model from the chronos library.
- For **N-BEATS** and **PatchTST**, the same dataset was used, given the same limitation as mentioned previously. However, a validation set was required for hyperparameter tuning. After selecting appropriate hyperparameters, the models were trained on the training set and evaluated on the test set. Implementations from the NeuralForecast library were used for both models.
- For the **linear regression**, **random forest regressor**, and **gradient boosting regressor** models, we included both water level and weather data. Feature selection was conducted to reduce the number of features, resulting in 42 features for linear regression, 30 for random forest, and 36 for gradient boosting. After feature selection, hyperparameters for the random forest and gradient boosting models were tuned, and the data for linear regression was normalized. The models were then trained on the training set and evaluated on the test set using scikit-learn's implementations.

The hyperparameters used for training are listed in Appendix A, while a description of the selected features is provided in Appendix B.

4 Results

The results for all tested models across various prediction horizons are presented in Table 1. The reported R^2 scores were calculated based on the differences in water levels; if absolute water levels had been used, the R^2 scores would have been significantly higher. For example, in the case of CHRONOS with 1-day ahead predictions, the R^2 score is 0.725 for relative level differences and 0.998 for absolute water levels.

Among the models, linear regression achieved the highest performance, followed by the random forest. In contrast, the more complex methods, including deep learning models and the foundation model, showed generally lower performance, with the exception of the 1-day prediction horizon, where N-BEATS outperformed the tree-based models. Notably, the R^2 scores decrease as the prediction horizon lengthens, with a more pronounced decline observed in the deep learning and the foundation models compared to the traditional batch learning methods.

Figures 2 and 3 display the predictions from CHRONOS, PatchTST, and linear regression compared to the true data for the 1-day and 5-day prediction horizons. It is evident that the predictions from CHRONOS and PatchTST begin to exhibit a rightward shift as the horizon extends. Figure 1 visualizes the R^2 scores for all models across the different prediction horizons.

Table 1: R^2 Scores for Different Prediction Horizons and Models.

Methods	1 day ahead	2 days ahead	3 days ahead	4 days ahead	5 days ahead
Chronos-large	0,725	0,365	0,175	0,04	-0,09
GradientBoostingRegressor	0,640	0,603	0,527	0,556	0,545
RandomForestRegressor	0,726	0,697	0,701	0,706	0,691
N-BEATS	0,742	0,397	0,17	-0,03	-0,143
PatchTST	0,721	0,394	0,215	0,109	-0,02
LinearRegression	**0,792**	**0,781**	**0,785**	**0,784**	**0,780**

The best and second-best results are bolded and underlined respectively.

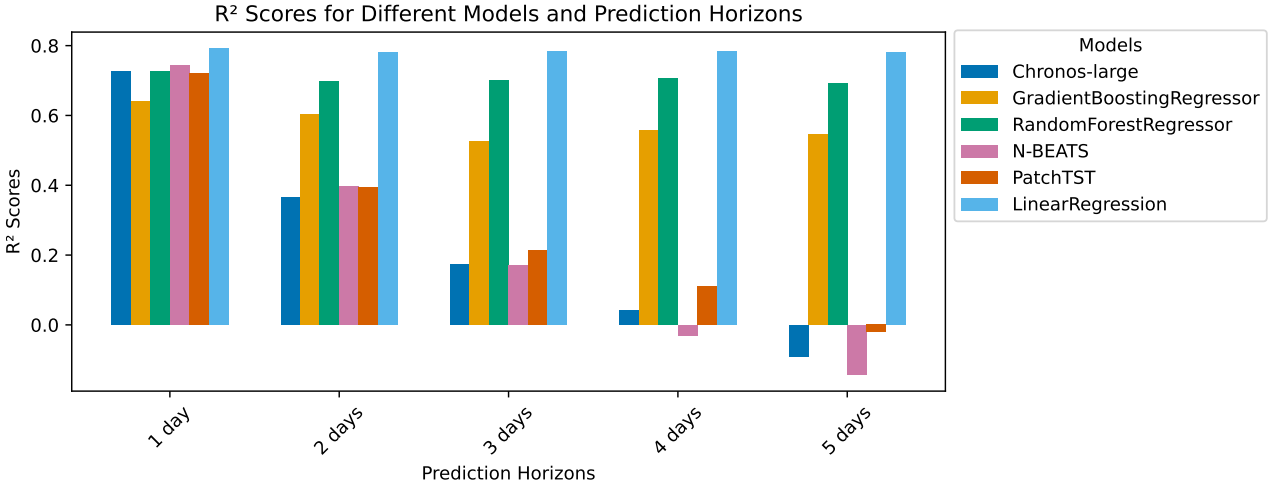

Figure 1: R^2 Scores for All of the Methods and Prediction Horizons.

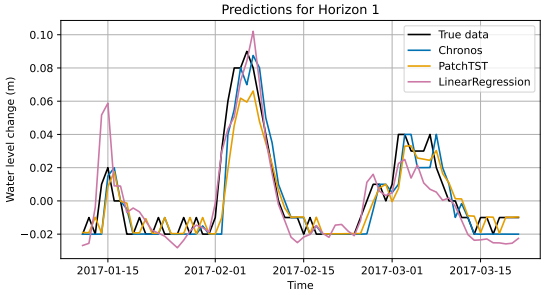

Figure 2: Example Predictions for Three Models for 1-Day Prediction Horizon.

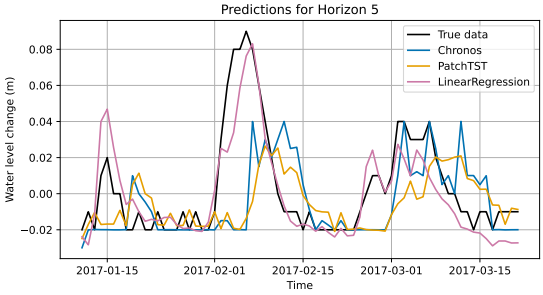

Figure 3: Example Predictions for Three Models for 5-Day Prediction Horizon.

The results indicate that traditional methods, when supplemented with relevant contextual features, outperform more complex models that do not incorporate such data. While the 1-day ahead predictions show comparable performance across all methods, as the prediction horizon extends, the accuracy of CHRONOS, PatchTST, and N-BEATS declines sharply. In contrast, the traditional models, supported by contextual features, maintain their predictive accuracy much more effectively, as shown in Figure 1.

A closer examination of the predictions in Figures 2 and 3 reveals that for 1-day ahead predictions, all models track the true data closely. However, in the 5-day ahead predictions, models lacking contextual data begin to exhibit a rightward shift in their predictions. This likely occurs due to the absence of contextual information, causing these models to lag in capturing the true trajectory of water levels. In contrast, models with access to weather data can predict further ahead by accounting for factors such as the impact of rainfall patterns on water levels.

An unexpected finding is that among the baseline models, linear regression outperforms the more sophisticated methods. For instance, in the article [9], while linear regression produced strong results, it did not surpass the performance of the other two methods.

5 Conclusion and Future Work

After evaluating all models on the groundwater level dataset, we observed that traditional methods, when equipped with relevant features, consistently outperformed newer and more sophisticated techniques, particularly as the prediction horizon lengthened. This suggests that the emphasis on developing the most powerful deep learning or foundation models for time series predictions may be overstated. With thoughtful selection of contextual features, even the simplest models can outperform modern approaches, which is a significant finding for fields with sufficient contextual data, such as data-driven environmental modelling.

To enhance the robustness of our evaluation, future work could involve testing additional methods, expanding the analysis to include more measurement stations and surface water level data, and incorporating deep learning models that support multivariate time series, such as N-BEATSx [11] and N-HiTS [3]. Further insights could be gained by exploring foundation models with multivariate support, such as TimesFM [4], as well as some more univariate models, like TimeGPT-1 [6]. Future research could also compare the inference times of various models and assess performance across different time series lengths.

B Selected Features

Due to the large number of features selected by the feature selection algorithm, we provide a summarized description of the most frequently chosen features. The features that appeared most often include shifts and averages of precipitation, precipitation forecasts, temperature, altitude difference, cloud cover, humidity, and snow accumulation. Notably, the majority of selected features were derived features we generated, with only approximately one original feature being selected per model.

In Table 4, the most common shifts and averages for each individual model are presented. The table indicates that shifts and averages of varying lengths were selected, with a slight preference for shorter ones.

Table 4: Most Frequently Selected Shifts and Averages for Various Methods.

Method	Shifts (days)	Averages (days)
GradientBoostingRegressor	4, 10	2, 6
RandomForestRegressor	2, 6	3, 9
LinearRegression	2, 10	2, 7
Combined	**2, 10**	**2, 3**

Interactive Tool for Tracking Open-source Artificial Intelligence Progress on Hugging Face

Abstract

Given its increasing importance in our daily lives, Artificial Intelligence has become a prominent subject that needs extensive investigation and understanding. This study presents an analysis of the open-source community in the field of Artificial Intelligence (AI). Various questions arise anytime AI is introduced. open-source AI introduces additional concerns. Should artificial intelligence (AI) be universally accessible, or should it be restricted to private use? Is it worthwhile to offer basic models to the broad user population? We chose the most important data from the primary website in the field, Hugging Face. We have developed a tool that allows for straightforward monitoring of the progress of various open-source AI models using data obtained from their leader board. The platform offers accessible and valuable information about various AI models, including their architectures and the activities of authors. Through performing a quick review with our tool, it becomes evident that the open-source community is becoming large and has an undeniable impact on the AI community.

Keywords

LLM, open-source, AI, Hugging Face

1 Introduction

Artificial intelligence, particularly large language models (LLMs), is an important topic in the computer industry today. Despite the numerous fears and dogmas around it, it is certain that AI has become an integral aspect of our lives. This research has specifically concentrated on the development of a tool for monitoring the impact of the open-source community in the area of artificial intelligence. As implied, these models are accessible to all individuals. There is considerable debate on whether this type of technology should be universally accessible. We wanted to investigate if the open-source community is actively contributing to the development of the field, regardless of one's philosophical convictions. Due to the substantial computational requirements, it was previously impossible to execute Large Language Models on personal computers. As increasingly compact versions with impressive capabilities are being produced, this scenario undergoes a significant transformation. Currently, it is feasible to execute your own model, as long as it is of a modest enough size, on a home computer's graphics processing unit (GPU), even if the GPU is a few years old [9]. The rise in accessibility also enables a larger community to test and develop new solutions and build on top of existing models. We believe that there is a big lack of tools for monitoring the impact of this movement.

Hugging Face [1] has grown into one of the primary platforms for the open-source community. Users are able to download and interact with all significant open-source models. Subsequently, users have the option to publish their models on the platform and compare their performance by adding them to the leaderboard, where all the models are benchmarked and ranked. The open-source community relies heavily on the distribution of models by large corporations, as creating a model from scratch is a hard undertaking [9]. This tool facilitates collaboration among open-source contributors, enabling them to collectively generate social media content, exchange ideas, and even publish concise articles. In addition to the models, they have the ability to generate and upload useful datasets. It represents the most advanced and innovative developments in the field of open-source AI and Machine learning.

An issue that has been observed is the absence of effective visualization tools on Hugging Face, which would enable users to easily see patterns and gain a comprehensive understanding of the open-source AI area. In order to address this issue, we have developed a sophisticated tool that offers users various viewpoints on the data.

2 Literature review

Large Language Models (LLMs) have proven essential in enhancing software engineering (SE) tasks, demonstrating their effectiveness in code comprehension Similar to conventional software engineering tools, open-source cooperation is essential for achieving superior products in this area. [8]

The article authored by Patel et al. [9] emphasizes the significance of the open-source AI community and elucidates its rapid growth in the wake of major industry leaders like Google, Microsoft, and OpenAI. An important milestone in this subject is often emphasized as the day when the LLama model was initially made available to the open-source community. The community promptly recognized the possibilities and potential involved in this release.

Due to its continuous growth, Hugging Face has emerged as the primary platform for exchanging machine learning (ML) models, resulting in an increasing level of complexity. A relational

database called HFCommunity was established to facilitate the analysis and resolution of this issue [1].

As previously said, open-source AI models offer an extensive range of possibilities. At the recent conference, the authors [12] demonstrated their effective use of Hugging Face. Due to the significant difficulty in developing a model with broad intelligence, researchers have merged ChatGPT capabilities with models from HuggingFace using agentic architecture to get impressive results in multiple domains. ChatGPT was tasked with creating a plan of action and assigning specific duties to each open-source model based on their own areas of expertise. This is an excellent demonstration of the influence and capabilities of the open-source community, given the familiarity with open models and their capabilities.

The article [6] examines the vulnerabilities associated with open-source AI. A much higher number of repositories with high vulnerabilities has been discovered compared to those with low vulnerabilities, particularly in root repositories. This emphasizes the significance of ensuring the security of technology in order to facilitate its utilization.

In a recent paper [10], authors have analyzed the transparency of Hugging Face pre-trained models regarding database usage and licenses. The analysis revealed that there is often a lack of transparency regarding the training datasets, inherent biases, and licensing details in pre-trained models. Additionally, this research identified numerous potential licensing conflicts involving client projects. 159,132 models were examined. It was found that merely 14% of these models explicitly identify their datasets with specific tags. Furthermore, a detailed examination of a statistically significant sample comprising 389 of the most frequently downloaded models showed that 61% documented their training data in some form.

3 Methodology

We obtained the data by extracting the Open LLM Leaderboard from Hugging Face [2] by saving the data server sent to the client. This data contains information about repositories of models that are currently on the leaderboard and the models that are waiting to be evaluated for the leaderboard. A Python pipeline was developed to clean and enrich this data available on [2]. The leaderboard data includes model architecture and precision as well as the model type and performance on the following benchmarks: ARC[3], HellaSwag[14], MMLU[5], TruthfulQA[7], Winogrande[11] and GSM8K[4]. In addition to the data provided on the leaderboard, additional information on the given models was obtained by using the HF API client. This included data about repository contributors, tags, base models, used datasets, and repo activity. It is important to note that the data is self-reported by the developers and is not enforced by HuggingFace. Additionally, the leaderboard includes duplicates due to developers being able to replace models in the repository with different models under the same name. This means the duplicates have the same repository data but distinct performances. Due to the inability to programmatically determine the current model in the repository, we chose the best-performing model under the repository name as the model representing the repository when removing duplicates. Thus, all datasets were generated for further utilization. The following analysis was conducted using the R programming language. The data was mostly studied via the perspective of time, as our focus was on identifying any obvious trends. The data was categorized using several criteria, such as model type, model architecture, and amount of parameters. The data was initially selected and aggregated to ensure that all crucial components were easily accessible. All models that were categorized as flagged have been excluded from the dataset. In addition, we have collected data on the authors' activities and conducted a study on that particular aspect. Once the data had been cleaned and prepared for visualization, we utilized the R ggplot library to create visual representations of the data. A comprehensive R Shiny app was developed by aggregating all the visuals. We chose to utilize Shiny because it is a great option for constructing interactive data analysis solutions due to several factors. Firstly, it enables the development of web applications that are capable of responding and adapting to real-time changes and user interactions. This simplifies the process of exploring and analyzing data. Shiny easily incorporates with R, utilizing its robust statistical and graphical functionalities to generate complex, interactive visualizations without the need for experience in web technologies such as HTML, CSS, or JavaScript. [13] Finally, our application was deployed to a server, making it accessible online.

4 Results

The outcome of this study is the tool we have developed. The link may be accessed via the following URL. [3]. It has six distinct viewpoints, all conveniently accessible inside its tab. The initial figure, labeled as 1, displays both the count of new models and the distribution of various model types. Hugging Face has identified five distinct categories of models: basic mergers and moerges, fine-tuned on domain-specific datasets, chat models, continuously pretrained models, and pretrained models. If the model did not belong to any of these classes, its type was classified as unknown. The user has the ability to effortlessly choose their preferred categories, along with the desired time frame and unit of aggregate (daily, weekly, or monthly). This allows the viewer to clearly observe the evolution of model types and their popularity over time. It is evident that fine-tuned models are predominantly utilized. This is logical, as users are adapting base models by training them on unique datasets to achieve specialization. Also, we can see that merged models are a relatively recent phenomenon.

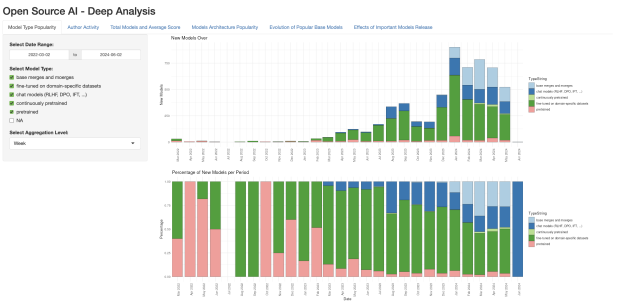

Figure 1: Popularity by model type over time

The second view, referenced as 2, has two interconnected visualizations. The upper section displays the activity of the top 10 authors within a specific range of dates. The display showcases every model they have developed, along with its corresponding type. The lower section presents the average benchmark score for

[2]https://github.com/VakeDomen/HF_analysis

[3]https://oai.dltlt.famnit.upr.si/

each model, organized by author. This visualization enables users to effortlessly monitor the most prominent authors and observe their patterns and accomplishments in model development over time. Users have the ability to effortlessly choose a certain range of dates and also narrow down the list to the top 10 authors according to their preferences. It is evident that leading authors typically do not adhere to trends and consistently provide models of similar type.

Figure 2: Top authors activity over time

The following perspective 3 illustrates two aspects. The first aspect is the alteration in the average benchmark score for each model type as time progresses. The display showcases the top-performing model for each category and time interval (daily, weekly, or monthly). In addition to the dots representing each model, we have incorporated a smooth line to aid the user in seeing the temporal changes for a particular model type. Following the first visualization, we have included a second visualization that displays the total number of models for each model type within the chosen period range. Through these visualizations, users can easily identify the model type that experienced the most improvement and the model types that were mainly produced. We can see the trend, which indicates that open-source AI models are improving, as evidenced by the improvement in average benchmark scores across most of them. The overall number of models is rapidly increasing, indicating a rise in the popularity of open-source AI models.

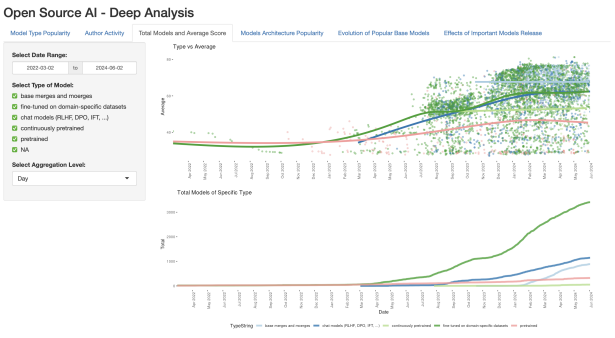

Figure 3: Change of benchmark score and total models per type over time

The fourth perspective, as seen in Figure 4, examines the changing popularity of various model architectures throughout time. The following architectures have been chosen for this specific objective: LLama, Mixtral, Mistral, Qwen2, Gemma, Phi, Opt, GPT2, and GPT2-NeoX. All architectures that did not fit into any one category were classed as "Other". This perspective has two graphics that depict popularity. The first comparison assesses the popularity of a model relative to itself, depending on the number of new models introduced before. The second one compares it to the average number of new models created, taking into account their architecture. Both are depicted by coloring the area, as it is the most convenient way to track. Users may analyze the fluctuation in popularity of well-known model architectures over time and examine how the rising popularity of a particular architecture might impact the popularity of a certain architecture of interest. The lower plot indicates that LLama and Mistral are the predominant models; nonetheless, they have experienced fluctuations throughout time, as visible on the upper plot.

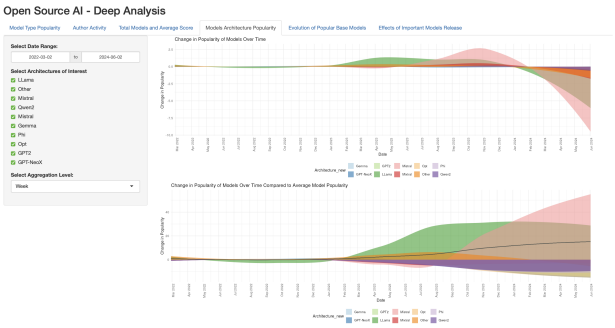

Figure 4: Change of popularity of main architectures over time

The graphic labeled as 5 illustrates the progressive improvement of the key base models developed by famous companies. This was accomplished by isolating each incremental improvement in score over time, using the base model as a reference. In order to fulfill this objective, we have chosen five distinct variations of LLama, Mistral, and Mixtral, as well as three iterations of Phi. The user may easily observe the overall improvement in benchmark scores for each base model. In addition, users have the ability to view the overall duration required for the model to achieve its maximum performance. We have included a feature that enables users to toggle the visibility of model labels, hence enhancing visibility and facilitating more in-depth examination according to their preferences. This allows the user to observe the speed at which specific models reached their peak performance and the extent of their improvement relative to the base models.

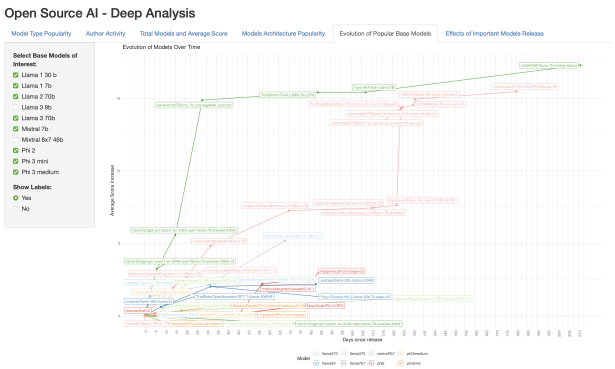

Figure 5: Evolution of famous base models

The final view, as depicted in Figure 6, illustrates the impact of significant releases on the popularity of various model designs. As we have employed identical model designs to those in view four, we have extracted and categorized all significant release dates of these models. The user has the option to choose the time unit for aggregate, which can be either day, week, or month. Users may quickly analyze the impact of significant releases and observe how they influence the popularity and mass creation of specific models. We can observe the evident impact of the recent releases of LLama and Mistral for their popularity.

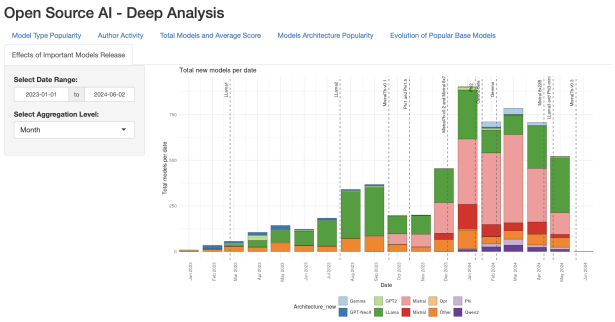

Figure 6: Effect of big releases on architecture of produced models

5 Conclusion and future work

Given the growing importance of Artificial Intelligence in modern culture, it is beneficial to explore the free solutions that are accessible rather than just depending on commercial alternatives. This paper offers valuable insights into a tool designed to simplify the examination of trends in open-source AI in a user-friendly manner. It offers various viewpoints and enables users to acquire knowledge and reach certain conclusions about the subject. Hugging Face has the capability to function as an excellent tool for finding a certain model. As time progresses, open-source AI is expected to provide a growing contribution to the AI community and provide more specific applications for models that could be ignored by big organizations.

We aim to enhance the functionality of our Shiny application by incorporating more perspectives and expanding the range of data interaction options. Our objective is to ensure that the system is as updated as possible. Besides that, we want to conduct a comprehensive analysis of the data to identify patterns and correlations inside this group. We aim to assess the potential of these models and examine their capabilities and potential uses in addressing real-world issues. We would like to analyze the sustained popularity and efficacy of these models over a longer time frame.

Abstract

As social media usage increases, so does the volume of toxic content on these platforms, motivating the Machine Learning (ML) community to focus on automating hate speech detection. While modern ML algorithms are known to provide nearly human-like results for a variety of downstream Natural Language Processing (NLP) tasks, the classification of hate speech is still an open challenge, partially due to its subjective annotation, which often leads to disagreement between annotators. This paper adopts a perspectivist approach that embraces subjectivity, leveraging conflicting annotations to enhance model performance in real-world scenarios. A state-of-the-art multilingual language model for hate speech detection is introduced, trained, and evaluated using diamond standard data with metrics that consider disagreement. Various strategies for incorporating disagreement are compared in the process. Results demonstrate that the model performs equally or better on all evaluated languages compared to respective monolingual models and drastically outperforms on multilingual data. This highlights the effectiveness of multilingual and perspectivist methods in addressing the complexities of hate speech detection. The presented multilingual hate speech detection model is available at: https://huggingface.co/IMSyPP/hate_speech_multilingual.

Keywords

hate speech detection, inter-annotator disagreement, multilingual language modeling

1 Introduction

The phenomenon of hate speech, which is typically defined as offensive or derogatory language targeting individuals or groups based on characteristics such as race, religion, ethnic origin, sexual orientation, disability, or gender [2], has become a significant problem on social networks in recent years, with communities being increasingly exposed to toxic content as the networks grow and become more interconnected [13, 3]. Consequently, the Machine Learning (ML) and computational linguistics communities have begun developing content moderation strategies using advanced algorithms and Natural Language Processing (NLP) techniques to detect hate speech [10, 11]. However, a key challenge is the subjectivity of hate speech, as annotators often disagree due to diverse backgrounds and perspectives.

To address this challenge, researchers have proposed alternative methodologies to ground-truthing, including the incorporation of diverse perspectives into the training and evaluation pipelines of ML models [1, 14]. One such approach is introduced by [7], who train monolingual hate speech classifiers in several languages directly on datasets that include disagreement. As an alternative to gold-standard data, such data is referred to as diamond standard data, based on the assumption that more than one single truth exists. In terms of evaluation, the researchers focus on the evaluation of models from the perspective of disagreement, with the ultimate goal of estimating the agreement between the annotators themselves, as well as between models and annotators by using the appropriate metrics. Their main findings indicate that disagreement between annotators represents an intrinsic limitation to the performance that can be achieved by automated systems.

This paper aims to explore the potential of training a multilingual hate speech model, as well as further explore the ideas of incorporating inter-annotator disagreement in model training. Therefore, at the basis of this paper lie the following research questions:

- *How does the performance of multilingual hate speech classifiers trained on diamond standard data compare to the performance of monolingual models?*
- *How can inter-annotator disagreement be effectively incorporated into the classifier fine-tuning process?*

In light of these research questions, the expected outcomes are twofold: (1) multilingual classifiers trained on diamond standard data are anticipated to outperform monolingual models, and (2) incorporating inter-annotator disagreement is expected to enhance sensitivity to nuanced hate speech. These findings could benefit computational linguistics research and social media providers by informing the development of more effective content moderation algorithms.

2 Related Work

Several methods exist for incorporating disagreement into ML training pipelines [12, 5], but few focus on hate speech detection. One approach is presented in [7], where monolingual hate speech classifiers were trained for English, Italian, and Slovenian. These classifiers utilized diamond standard datasets sourced from YouTube and Twitter, employing a consistent annotation process for each language. Their main findings indicate that, according to the accuracy scores, the annotators demonstrated a high degree of agreement in approximately 80% of the cases across all three datasets. In terms of Krippendorff's ordinal alpha score, which considers both agreement by chance and the ordering of classes (from least to most severe), the agreement score is approximately

*The first author conducted the research with significant input from the second author, under the supervision and guidance of the third author. All authors contributed to writing the manuscript.

© 2024 Copyright held by the owner/author(s).
https://doi.org/https://doi.org/10.70314/is.2024.sikdd.7

0.6 for all three languages. Furthermore, the evaluation results indicate that the performance of each model aligned with the inter-annotator agreement, both in terms of accuracy and the alpha score. This implies that the performance of models is inherently constrained by the level of agreement among annotators. Consequently, when trained on diamond standard data, it is unlikely that the performance of these models can significantly surpass human performance.

This work was built upon these findings through investigating the potential of multilingual models to enhance hate speech detection, with the aim of broadening their applicability across diverse linguistic contexts. Additionally, strategies for incorporating annotator disagreement were explored, with the goal of improving model performance to approach human-level accuracy and agreement.

3 Method

This section details the methodology for training and evaluating the multilingual hate speech classifier presented in this paper. It begins with a brief overview of the datasets used, followed by an explanation of the chosen pre-trained language model that serves as the foundation for fine-tuning. The section concludes with a description of the methods employed for evaluating the models.

3.1 Datasets

Three monolingual datasets, i.e. the English (Youtube), Italian (Youtube) and Slovenian (Twitter) datasets, introduced in [7] served as the basis for our multilingual model. Each item was annotated by two annotators independently, assigned to one of four available classes: [Appropriate], [Inappropriate], [Offensive], and [Violent]. In the case of conflicting labels, both annotating instances were kept.

To explore strategies for incorporating disagreement, three multilingual datasets were created. First, the *Duplicate All* (DA) dataset, which contains all instances by their respective two annotators from the three monolingual datasets. Second, the *Duplicate Disagreement* (DD) dataset, in which instances where annotators disagreed appear twice with their respective conflicting labels, while instances that they agreed upon appear only once, creating a more balanced training set that reflects both agreement and disagreement, potentially preventing the models from being biased towards instances where annotators agree. And third, the *Remove Disagreement* (RD) dataset, which consists only of instances where annotators agree. Thus, the first two datasets contain diamond standard data, while the third dataset can be considered a gold standard dataset in which disagreement has been explicitly removed.

All instances in these datasets have undergone the same preprocessing steps, such as replacing links and usernames with placeholders. This step was undertaken to mitigate any potential biases associated with certain names, as discussed in [6]. Table 1 presents an overview of the label distribution across the three multilingual training sets. The datasets used for monolingual evaluation are the unmodified evaluation sets presented in [7].

Table 1: Label distribution of the multilingual train sets

Dataset	Acceptable	Inappropriate	Offensive	Violent
DA	191,677	11,005	112,833	7,145
DD	111,324	8,346	72,706	4,992
RD	80,573	2,661	40,255	2,161

3.2 Model Selection and Fine-Tuning

Our proposed multilingual hate speech model builds on the pre-trained XLM-R transformer model [4], chosen for its proven effectiveness in cross-lingual understanding and its ability to handle a wide range of languages. This provides a robust foundation for fine-tuning and optimization, particularly since English, Italian, and Slovenian—the languages used for fine-tuning—were included in XLM-R's pre-training. To explore various strategies for incorporating annotator disagreement during training, three model variants were fine-tuned on the previously presented datasets, referred to in the tables as MDA, MDD, and MRD, respectively.

To address class imbalance and enhance model performance on minority classes, a custom training loop with a weighted cross-entropy loss function was implemented, as proposed in [9]. The class weights were calculated to be inversely proportional to the frequency of each hate speech class within the training data. The hyperparameters for the fine-tuning process included a learning rate of 6×10^{-6}, a batch size of 8, and 3 training epochs. During the training phase, the AdamW optimizer was employed to optimize the model parameters. The fine-tuning process was implemented using PyTorch.

3.3 Model Evaluation

In terms of evaluation, the approach introduced in [7] was replicated in order to compare the performance of the multilingual classifiers to human judgment from the perspective of disagreement. This was achieved by employing identical measures to estimate the agreement between human annotators, as well as the agreement between annotators and models. Accuracy, F1 score and, most notably, Krippendorff's ordinal alpha were used to evaluate all models in this research.

Rarely used in ML applications, Krippendorff's alpha is a robust measure for assessing inter-rater reliability, accounting for agreement beyond what might occur by chance. It is applicable across various data types (nominal, ordinal, interval, and ratio scales) and is particularly effective in dealing with missing data. The value of Krippendorff's alpha ranges from -1 to 1, where 1 indicates perfect agreement and 0 suggests agreement equivalent to chance. Generally, an alpha above 0.80 is considered a strong agreement, while in hate speech datasets, the alpha values range from 0.25 to 0.65. For a detailed discussion, see Krippendorff [8].

4 Results

This section presents the evaluation results on the multilingual model and its variants. It starts with an evaluation from the perspective of inter-annotator and model-annotator agreement. Then, the class specific evaluation results, as well as a model comparison based on the models' average scores are presented. The models are also compared to monolingual baselines fine-tuned on data for their respective languages, including the BERT model for English, AlBERTo for Italian, and CroSloEngual for Slovenian, as presented in [7].

4.1 Inter-Annotator and Model-Annotator Agreement

The inter-annotator agreement was computed on the evaluation sets for each language using Krippendorff's alpha and accuracy. The same measures were also used to compute the agreement between the annotators and the models. The results are presented in Table 2.

Table 2: Inter-Annotator Agreement compared to model-annotator agreement in terms of Krippendorff's ordinal alpha (α) and Accuracy (Acc.) for the models Multilingual Duplicate All (MDA), Multilingual Duplicate Disagreement (MDD), and Multilingual Remove Disagreement (MRD) based on the language-specific evaluation sets

Dataset	Inter-Annotator Agreement		MDA		MDD		MRD	
	α	Acc.	α	Acc.	α	Acc.	α	Acc.
English	58.19	82.91	55.89	79.97	50.18	76.47	**57.90**	**81.41**
Italian	57.00	81.79	**58.29**	82.00	56.15	80.43	57.84	**82.69**
Slovenian	56.62	79.43	55.74	78.60	52.95	76.52	**55.15**	**78.84**

First, in the case of inter-annotator agreement, annotators agree around 80% of the time in terms of accuracy, with an accuracy score between 79% and 82% across all three datasets. However, accuracy does not account for class imbalance, nor the ordering of the classes. A more appropriate estimate of the agreement is computed through Krippendorff's ordinal alpha. Here, the annotators achieve an agreement score alpha in the values between 0.56 and 0.58 across the three languages.

Second, in terms of agreement between annotators and models, the same metrics were applied. The results demonstrate a consistent level of agreement between the models and annotators across all cases. Based on accuracy scores, all models align with at least one annotator approximately 80% of the time, with alpha values comparable to inter-annotator scores. In most instances, the models achieve the upper limit of inter-annotator agreement, and in some cases, even exceed it (e.g., Italian *Multilingual Duplicate All MDA*). This suggests that the models are effectively learning consistent patterns or biases that align well with one or more annotators. Such outcomes are expected in scenarios where annotator disagreement is largely due to subjective interpretation. This should not be construed as the model being inherently superior, but rather as an indication of its efficiency in modeling the predominant patterns present in the training data.

Third, a comparison between the multilingual variants shows that the *Duplicate Disagreement (DD)* strategy consistently shows worse alpha scores, meaning that emphasizing only on disagreement might be detrimental in training. No consistent difference between *Duplicate All (DA)* and *Remove Duplicates (RD)* is evident from the experiments.

4.2 Model Comparison

To evaluate the performance of the models across the four hate speech classes, the F1 score was used. Additionally, the combined (weighted) F1 score was computed for each model to assess their overall performance. To determine the best-performing model, the weighted F1 scores were averaged across all three languages. Table 3 shows the results achieved by each of the models on the English evaluation set. In the case of the English dataset, the results show that the multilingual model outperforms the baseline monolingual English model across all classes except the [Appropriate] class, a case in which it still performs competitively. The variant which achieved the highest score on the minority classes is the *MDA* model, with an F1 score of 39.16 for the [Inappropriate] class and an F1 score of 27.82 for the [Violent] class. This is most likely due to introducing the weighted cross-entropy loss function, which was effective in improving performance on underrepresented classes, a procedure which was not performed in [7].

Similar patterns emerge on the Italian dataset (Table 4). The multilingual model is competitive to the monolingual model while outperforming the Italian baseline on the minority classes. The highest scores on the most important classes [Violent] and [Offensive] were achieved by the *MDA* variant, once again showing the superiority of the *Duplicate All (DA)* strategy.

Table 3: Model evaluation results in terms of class-specific F1 scores on the English dataset. The Total score was calculated using the weighted F1 score. The first three models represent the monolingual baselines. The subsequent models represent the multilingual models

Model	Appropriate	Inappropriate	Offensive	Violent	Total
EN	**89.38**	28.95	68.36	24.17	**83.44**
IT	85.25	13.81	0.41	0.00	63.39
SL	88.01	25.17	49.69	2.88	77.71
MDA	86.10	**39.16**	68.24	**27.82**	81.09
MDD	83.33	34.16	65.07	24.52	78.20
MRD	87.43	29.90	**69.02**	27.27	82.18

In the case of the Slovenian dataset, the observed phenomena slightly differ from the previous ones. The evaluation results are presented in Table 5. Here, two of the multilingual variants (*MDA* and *RD*) outperform the Slovenian monolingual model overall, despite predicting worse on the [Appropriate] class. Notably, the monolingual model outperforms all models on the [Violent] class, which has not been the case for the other languages. This could be due to language specifics that the multilingual model fail to capture, or to the specifics of the CroSloEngual BERT which is also heavily pre-trained on Croatian and Slovenian data. Once again, the *DA* disagreement strategy shows slight superiority over *RD*.

Finally, Table 6 shows the average scores of all models, achieved by averaging their combined (weighted) F1 scores across all three languages. Summarizing the multilingual superiority, these final results show how monolingual models drastically falter on unseen languages, while the multilingual models have the capacity to reach the inter-annotator agreement ceiling for all languages.

While overall results show that the *Remove Disagreement (RD)* gold standard strategy for incorporating disagreement is best, one should be cautious when making such conclusions. Class-specific results show that the Duplicate All (DA) strategy outperforms in all the classes most relevant to hate speech detection, except for [Appropriate], which is the least relevant class. Another difference is that the *MDA* model involved training longer on the same data which might have resulted in improvement on minority classes and saturation on the majority class. For a future fairer comparison, the fine-tuning process on gold standard data should be adjusted accordingly. The *MDA* variant of the model is available at: https://huggingface.co/IMSyPP/hate_speech_multilingual.

5 Discussion

In recent years, automated hate speech detection has become crucial for moderating online content and mitigating the negative impact on social dynamics within online communities. This

MDD	78.86
MRD	**81.16**

research proposes a novel multilingual hate speech model to address these challenges on a broader scale. The following discusses the main findings.

First, the inter-annotator agreement and the agreement between annotators and models suggest that inter-annotator agreement sets an intrinsic limit on model performance. Models are limited by the quality and consistency of the annotated data, which directly affects their ability to accurately predict unseen data. However, incorporating areas of disagreement into model development can lead to more robust models capable of handling ambiguous cases by employing one of the several available strategies for incorporating disagreement.

Second, the multilingual model consistently surpassed the monolingual baselines, achieving the inter-annotator agreement ceiling across all languages. This success can be attributed partly to the ability to leverage patterns learned from multiple languages, partly to vast amounts of data incorporated into state-of-the-art pre-trained multilingual models, and partially to the class weighting scheme employed in the fine-tuning. These findings support the first research question, demonstrating that a multilingual hate speech classifier trained on diamond standard data outperforms its monolingual counterparts.

Finally, this research contributes substantially to hate speech classification in a multilingual context by introducing a novel multilingual hate speech detection model and making it available on the Hugging Face platform. Our model underscores the importance of incorporating inter-annotator disagreement into model development, challenging the reliance on gold standard data in subjective tasks, such as hate speech detection.

6 Conclusions

This paper advances automatic hate speech detection by introducing a novel multilingual model fine-tuned on the state-of-the-art XLM-R transformer. By leveraging multilinguality, the model significantly outperforms monolingual baselines, demonstrating its effectiveness across diverse linguistic contexts. This highlights the potential of multilingual approaches in improving hate speech detection, especially in scenarios where content spans multiple languages.

Additionally, this research incorporates inter-annotator disagreement into the fine-tuning process using diamond standard data, offering a valuable alternative to traditional gold-standard models. By embracing rather than ignoring annotator disagreement, the model better reflects the nuances of subjective annotations, enhancing its real-world applicability. However, while this approach shows promise, annotator disagreement continues to present challenges, indicating that further work is needed to fully address its impact on model performance.

Future research could extend this work by evaluating the models on additional languages, exploring alternative baseline models, refining strategies for incorporating annotator disagreement and handling minority classes. As online hate speech extends its impact, developing robust, multilingual content moderation systems is crucial to maintaining safe and inclusive digital environments.

Predicting Pronunciation Types in the Sloleks Morphological Lexicon of Slovene

Jaka Čibej[1,2]

Abstract

We present an experiment dealing with the automatic prediction of pronunciation types for lemmas in the *Sloleks Morphological Lexicon of Slovene*. We perform a statistical analysis on a number of mostly *n*-gram-based features and use a set of statistically significant features to train and test several machine learning models to discriminate between lemmas for which a phonetic transcription can be generated automatically using Slovene grapheme-to-phoneme (G2P) conversion rules (e.g. *Novak*), and lemmas with pronunciation that follows other G2P rules (e.g. *Shakespeare*).

Keywords

grapheme-to-phoneme conversion, pronunciation types, morphological lexicon, proper nouns, Slovene

1 Introduction

The *Sloleks Morphological Lexicon of Slovene* [2] is the largest open-access database containing machine-readable information on the morphological properties of Slovene lemmas (e.g. *miza* 'table', noun, common, feminine) and their inflected forms (e.g. *mize*, singular, genitive; *mizo*, singular, accusative). Since version 2.0 [3], each lemma and inflected form also contains accentuated forms (e.g. *míza*) and phonetic transcriptions in the International Phonetic Alphabet (IPA) and its equivalent X-SAMPA (e.g. IPA: /ˈmiːza/, X-SAMPA: /"mi:za/). Both transcriptions were generated automatically from accentuated forms, first in version 2.0 using a rudimentary rule-based system, then again in 3.0 with a greatly improved and linguistically informed rule-based grapheme-to-phoneme (G2P) conversion tool for Slovene.[1]

Rule-based G2P conversion for Slovene (particularly from accentuated forms) yields very good results and leaves only a minority of issues to be resolved manually because in terms of its orthographic depth, Slovene features a shallow orthography ([9]) in which each grapheme in the alphabet generally corresponds to one phoneme (see e.g. [4]) and the spelling-sound correspondence is relatively direct ([1]; [11]): the pronunciation rules allow for words to be pronounced correctly based on their graphemic representation, with some exceptions and several predictable phoneme assimiliations (such as the assimilation of voiceless consonant phonemes to their voiced equivalents *glasba* 'music', IPA: /ˈglaːzba/, or vice-versa, voiced-to-voiceless, *podpreti* 'to support', IPA: /pɔtˈpreːti/).

However, not all entries in Sloleks follow Slovene G2P principles. For a number of words, particularly proper nouns denoting people (*Shakespeare*, *Sharon*), locations (*Sydney*, *Birmingham*), inhabitants (*Newyorčan* 'New Yorker'), etc.; as well as adjectives derived from proper nouns (*aachenski* 'pertaining to Aachen', *Acronijev* 'belonging to Acroni'), the phonetic transcription cannot be generated using Slovene G2P rules. In such cases with foreign orthographic elements that indicate relations between graphemes and phonemes that are unusual for Slovene, Slovene linguistic and lexicographic practice (see e.g. [5]) first requires a transliteration into the closest equivalent using Slovene graphemes, which can then be used to generate the phonetic transcription using Slovene G2P rules (e.g. *Newyorčan* → *njújórčan* → IPA: /ˈnjuːˈjoːrtʃan/).

Because of this, it is necessary to discriminate between different *pronunciation types*: categories of words that follow Slovene G2P rules (*Slovene G2P*) and those that do not (e.g. *Other G2P*; more on this in Section 2). Pronunciation types denote the manner in which the phonetic transcription of the word can be generated. In some cases, assigning the pronunciation type to a lemma is trivial – if the lemma contains a grapheme that is not part of the Slovene alphabet[2] (e.g. *x*, *y*, *w*, *q*), it belongs into the *Other G2P* category (e.g. *Byron*, *Oxford*). There are, however, many exceptions that belong in the *Other G2P* category despite being comprised entirely of Slovene graphemes (e.g. *Matt*, *Sharon*).

In Sloleks 3.0, the first cca. 100,000 lemmas that had been part of version 2.0 were manually annotated with pronunciation types, whereas the 264,000 new entries (added automatically from the *Gigafida 2.0 Corpus of Modern Standard Slovene* [6]) still lack this information. Because manual annotation from scratch is time-consuming, we performed an experiment to determine to what degree the pronunciation type can be predicted automatically by relying on the scarce linguistic and morphosyntactic information that can be extracted from an individual lemma.

The paper is structured as follows: we describe the dataset that was used for the statistical analysis and machine learning experiment (Section 2), as well as the process of feature selection (Section 3). We train several machine-learning models and evaluate their performance using 10-fold cross-validation (Section 4). Finally, we manually evaluate a sample of automatically annotated entries (Section 5) and conclude the paper with our plans for future work (Section 6).

[1]The Slovene G2P tool is part of *Pregibalnik*, a piece of software used for the automatic expansion of the *Sloleks Morphological Lexicon of Slovene*: https://github.com/clarinsi/SloInflector It was developed within the *Development of Slovene in the Digital Environment* project. The Slovene G2P converter is also available as an API-service: https://orodja.cjvt.si/pregibalnik/g2p/docs

[2]Although *ć* and *đ* are not part of the Slovene alphabet, they are phonemically transparent and frequently occur in names of Slovene citizens, so they are not counted as foreign characters for the purposes of this task.

Acronym	845	0.23%
Slovene G2P with minor deviation	113	0.03%
Abbreviation	70	0.02%
Ambiguous G2P	69	0.02%
Symbol	49	0.01%
Total	**365,340**	**100.00%**

Table 2: Lemmas in Sloleks 3.0 with *Other G2P* pronunciation type by Morphosyntactic Properties

Morphosyntactic Properties	Frequency	%
Adjective, possessive	1,092	35.62%
Noun, proper, masculine	958	31.25%
Noun, proper, feminine	713	23.26%
Adjective, general	142	4.63%
Noun, common, masculine	127	4.14%
Noun, common, feminine	20	0.65%
Adverb, general	10	0.33%
Noun, common, neuter	2	0.07%
Verb, main, imperfective	2	0.07%
Total	**3,066**	**100.00%**

2 Dataset

Sloleks 3.0 contains a total of 365,340 entries, but only approximately 28% have been manually assigned one of 8 pronunciation types[3] (as shown in Table 1). For the classification task, we focus only on the two most frequent pronunciation types (*Other G2P* and *Slovene G2P*). [4]

In terms of their morphosyntactic features, the *Other G2P* lemmas mostly consist of possessive adjectives and proper nouns, collectively accounting for cca. 90% of the category (as shown in Table 2), but only 15% of the portion of Sloleks annotated with pronunciation types.

The final dataset for statistical analysis and machine learning consisted of 94,863 *Slovene G2P* lemmas (e.g. *dekadentnost*, *Košak*, *prefiltriran*) and 3,066 *Other G2P* lemmas (e.g. *Elizabeth*, *Presley*, *Sinclaire*).

3 Statistical Analysis and Feature Selection

From each lemma, we extracted a series of features that could help discriminate between the two classes: (a) percentage of *Slovene G2P* graphemes within the lemma (i.e. graphemes of the Slovene alphabet as well as *ć* and *đ*); (b) morphosyntactic features (e.g. *noun*, *proper*, *masculine*); (c) relative frequencies[5] of character-level uni-, bi-, and trigrams within the lower-cased lemma (e.g. *Matt* $\rightarrow f_r(m)$, $f_r(a)$, ..., $f_r(ma)$, $f_r(at)$, ..., $f_r(mat)$, ...); (d) relative frequencies of character-level uni-, bi-, and trigrams from a robust CVC-conversion of the lemma, substituting consonant graphemes with *C* and vowel graphemes with *V* (e.g. *Matt* $\rightarrow$ *CVCC* $\rightarrow f_r(C)$, $f_r(V)$, ..., $f_r(CV)$, $f_r(VC)$, ..., $f_r(CVC)$, ...); (e) relative frequencies of character-level uni-, bi-, and trigrams from a finegrained CVC-conversion of the lemma[6] (e.g. *Matt* $\rightarrow$ *ZVKK* $\rightarrow f_r(Z)$, $f_r(V)$, ..., $f_r(ZV)$, $f_r(VK)$, ..., $f_r(ZVK)$, ...)

For (c), (d), and (e), the initial and final uni-, bi-, and trigrams of the lemma were extracted separately as well, as in some cases the position of the *n*-gram in the word can be indicative of one class over another.

For general character-level *n*-grams, the first 1,498 with a frequency of at least 500 across all Sloleks 3.0 lemmas were analyzed; these cover cca. 88.34% of all *n*-gram occurrences. For robust CVC and finegrained CVC *n*-grams, all were analyzed. We performed the Kruskal–Wallis H test [7] (k=2, n=97,056) on a total of 6,148 features, out of which 2,490 (40%) were statistically significant.[7] Statistically significant features by categories are shown in Table 3. 1,146 features are more indicative of *Slovene G2P* and 1,344 are more indicative of *Other G2P*. As shown in Table 4, only three of the top 10 general *n*-grams indicative of *Other G2P* actually contain non-*Slovene G2P* characters, confirming that detecting lemmas from the *Other G2P* category is more complex and requires more than simply taking into account non-*Slovene G2P* graphemes.

Table 3: Statistically Significant Features by Category

Feature Category	Number
Percentage of *Slovene G2P* characters	1
Morphosyntactic features	3
General character-level *n*-grams	1,119
Initial character-level *n*-grams	398
Final character-level *n*-grams	468
General robust CVC *n*-grams	66
Initial robust CVC *n*-grams	44
Final robust CVC *n*-grams	39
General finegrained CVC *n*-grams	157
Initial finegrained CVC *n*-grams	102
Final finegrained CVC *n*-grams	93
Total	**2,490**

4 Pronunciation Type Prediction

The identified features (along with several placeholder *n*-grams to take into account any graphemes not covered in the initial dataset) were taken into account to develop a custom vectorizer that converts a given lemma and its lexical features based on the MulText-East v6 (MTE-6) Morphosyntactic Specifications for

[3]It should be noted that all the inflected forms within the entry effectively inherit the pronunciation type.

[4]Symbols in Sloleks are rare, along with entries within the *Ambiguous G2P* category (where an entry can either follow Slovene G2P rules or not, depending on the context – e.g. *Amanda* as a Slovene name: /amˈaːnda/; or as an English name with a pronunciation adjusted to the Slovene set of phonemes: /əmˈɛːnda/). Abbreviations and numerals are easily identifiable, and while acronyms have a separate manner of generating phonetic transcriptions which also depends on their morphological patterns, they are also mostly identifiable with rules. Because of its rarity and similarity to *Slovene G2P*, the *Slovene G2P with minor deviation* category was merged into *Slovene G2P* for the classification task.

[5]Relative frequencies were calculated as $f_r(x_n) = f_a(x_n)/\sum f_a(y_n)$, e.g. the absolute frequency of *n*-gram *x* of length *n* within the lemma divided by the sum of absolute frequencies of each *n*-gram *y* of length *n* within the lemma.

[6]In the finegrained CVC-conversion, consonant graphemes were generalized into more finegrained categories, e.g. graphemes denoting Slovene sonorants (M), voiced (G) and voiceless obstruents (K), foreign consonants (X), etc.

[7]Effect size was calculated as $\eta^2 = (H - k + 1)/(n - k)$, as reported in [10].

Table 4: Top 10 Statistically Significant General Character-Level *n*-Grams by Effect Size (η^2)

n-Gram	H	p	η^2	Means
y	11509.36	$p \leq 0.0001$	0.1186	$\mu_S < \mu_O$
w	9595.25	$p \leq 0.0001$	0.0989	$\mu_S < \mu_O$

Table 5: Model Performance Based on 10-Fold Cross-Validation

Model	A	BA	P	R	F1	ROC AUC
LinearSVC	**99.08**	**87.87**	**96.36**	**87.87**	**91.64**	**98.89**
Multin. NB	97.38	79.17	78.12	79.17	78.62	96.55
kNN (k=5)	98.25	75.17	93.67	75.17	81.74	91.63
Majority	96.87	-	-	-	-	-

Slovene[8] into a 2,500-dimensional numerical vector. The entire dataset was converted into vectors and split into a training set (80%) and a test set (20%), both stratified by class. Three models[9] (Linear Support Vector Classifier (LinearSVC), Multinomial Naive Bayes Classifier (Multin. NB), and k Nearest Neighbors Classifier (kNN)) were trained and evaluated with 10-fold cross-validation. The results are listed in Table 5[10] and show that LinearSVC outperforms the other two models. All three exhibit above-baseline accuracy compared to the majority classifier, but Multinomial NB and kNN perform much worse in terms of balanced accuracy as well as precision and, in case of kNN, recall. Recall is also somewhat lower with LinearSVC, which is to be expected – some *Other G2P* lemmas might contain no indicative *n*-grams and are thus hard to detect; on the other hand, once identified, the model is very precise in its prediction.

Table 6 shows the confusion matrix for the LinearSVC model tested on the 20% stratified test dataset. The model very rarely misclassifies *Slovene G2P* lemmas, and more frequently errs with *Other G2P* lemmas. A closer inspection of the misclassified *Slovene G2P* examples reveals several errors in the original dataset: *Beethoven*, *Ratzinger*, *Rotterdam*, *Franco*, *Oberstdorf*, and *Keller* were in fact correctly classified as *Other G2P*, but they are miscategorized as *Slovene G2P* in the original dataset. Other misclassifications include examples of foreign proper nouns and possessive adjectives that contain unusual grapheme combinations for Slovene (e.g. *Andreas*, *Aurelio*, *Hilton*, *Simpsonov*), but their pronunciation can still be derived from their graphemic representation (e.g. *Andreas* → IPA: /and'reːas/).

On the other hand, *Other G2P* lemmas misclassified as *Slovene G2P* include *Andersonov*, *Atkinsov*, *Batmanov*, in which the grapheme

[8]MTE-6: https://nl.ijs.si/ME/V6/msd/html/msd-sl.html The vectorizer uses Slovene morphosyntactic tags, e.g. *Slz* (S – noun, l – proper, z – feminine).
[9]All models were trained using the Python library *scikit-learn*. [8]
[10]A, BA, P, R, and F1 refer to accuracy, balanced accuracy, macro-precision, macro-recall and macro-F1, respectively.

Table 6: Confusion Matrix for Linear Support Vector Classifier

True → ↓ Predicted	Slovene G2P	Other G2P	∑
Slovene G2P	**18,939**	140	19,079
Other G2P	34	**473**	507
∑	18,973	613	-

Table 7: Confusion Matrix for Manual Evaluation

True → ↓ Predicted	Slovene G2P	Other G2P	∑
Slovene G2P	**86**	9	95
Other G2P	14	**91**	105
∑	100	100	-

'a' is pronounced as /ɛ/, but this cannot be discerned from the graphemic representation itself. Other misclassified examples are more obviously pertaining to *Other G2P*, e.g. *Dorfmeister*, *Faulknerjev*, *Flaubertov*, *Heisenbergov*, *Balfourjev*. This might indicate that not all indicative *n*-grams have been included as features (e.g. 'ei', 'ou'), possibly for lack of evidence in the original dataset or because they are less frequent and have not been included in the initial batch of statistical tests. As the lexicon expands with new entries, the model will be updated with new examples and new features to potentially improve performance.

5 Manual Evaluation

We trained a new instance of the LinearSVC model on the entire dataset and used it to annotate the remaining cca. 264,000 lemmas from Sloleks 3.0 with no pronunciation type, resulting in 86,730 lemmas with *Other G2P* and 177,808 lemmas with *Slovene G2P*.

We performed a preliminary manual evaluation consisting of a random sample of 100 examples from each class. The results are shown in the confusion matrix in Table 7. Although the sample is too small to be representative of the whole, it indicates that the model performs well even on unseen data, achieving an accuracy of 88.50% (P=0.91, R=0.87, F1=0.89) over a majority baseline accuracy of 50.00%.

The misclassifications of *Other G2P* as *Slovene G2P* include examples such as *Mukhamedov*, *Beatli*, *Livenza*, and *Preidler*, with limited indicators that the words belong to the *Other G2P* category. Most graphemes in these examples are pronounced according to *Slovene G2P* criteria, with the exception of individual *n*-grams ('nz', 'ei', 'kh'), some of which have not been included in the set of features. In other examples, only one or two vowel graphemes are indicative of *Other G2P* pronunciation (e.g. *Trendlina*, which is also a lemmatization error; the correct lemma is *Trendline*; and *Sanberg*), and the pronunciation of single vowel graphemes appears harder to predict than consonant graphemes or combinations thereof.

Similarly, the misclassifications of *Slovene G2P* lemmas as *Other G2P* lemmas include examples such as *Doneck*, *Barson*, *Bronson*, *Piersanti*, and *Faustini*. While these are proper nouns of foreign origin, their Slovene pronunciation can either be fully discerned from their graphemic representation (e.g. *Doneck* → IPA: /dɔ'neːtsk/), or it only differs slightly from what Slovene

grapheme-to-phoneme conversion would produce (e.g. *Faustini* → automatically converted IPA: /faus'ti:ni/; correct IPA: /fa͡us'ti:ni/).

6 Conclusion

In the paper, we presented the results of an attempt to automatize the assignment of pronunciation types to lemmas in the *Sloleks Morphological Lexicon of Slovene*. The results show that a model based on a series of mostly *n*-gram features can provide good results when discriminating between *Slovene G2P* and *Other G2P* categories, with the best performance achieved by the Linear Support Vector Classifier. However, there is still room for improvement, particularly in terms of recall – a number of *Other G2P* lemmas from the test set were misclassified as *Slovene G2P*, while those classified correctly were classified with a relatively high precision score. *n*-grams that are statistically significant as indicative of one class have proven to be useful features for model development, but because they are not evenly distributed and occur sporadically in different lemmas, it would make sense to further improve the model by performing the same statistical analysis (as described in Section 3) on the long tail of less frequent *n*-grams to prepare a more comprehensive list of indicative *n*-grams. The current version of the model is very light-weight and additional features should not cause the model to become overencumbered.

There are several possibilities for further development of the model. Firstly, instead of using relative frequencies of *n*-grams as features, it would be useful to test how different measures such as TF–IDF, absolute frequencies, or even Boolean values influence the performance of the model, and potentially also test several other machine learning algorithms (e.g. Random Forest Classifier). Secondly, while the other pronunciation types from Sloleks 3.0 (acronyms, abbreviations, etc.) are relatively easily identifiable (but much less frequent), in the next step, it would be informative to include them in the training set and test out the model's performance on the full set of categories. Thirdly, a statistical analysis should be performed on the probabilities with which the model makes decisions and to what degree they correlate with the percentage of graphemes that differ from the shallow orthographical Slovene G2P rules (e.g. *Anderson*, with arguably only 'a' not following Slovene G2P rules; vs. *Châteaux*, where the majority of graphemes are pronounced completely differently compared to Slovene G2P rules). This would require the preparation of a separate dataset in which graphemes are manually aligned to either the graphemes of their transliterated Slovene graphemic forms (*Newyorčan* → *njújórčan*) or their Slovene IPA transcriptions. By assigning scores that reflect the degree of orthography depth for the individual lemma, it would be possible to use the dataset to train a regression model.

Similarly, *Other G2P* lemmas from Sloleks 3.0 can be manually annotated with their language of origin and transliterated according to the recently published transliteration rules of *Pravopis 8.0*,[11] the new orthographic manual of Slovene, which at the time of writing this paper is still in development. Such a dataset would enable the development of a model for language identification for individual lemmas, and, ultimately, a model for automatizing transliteration of lemmas of foreign origin into their Slovene equivalents. As of now, no such tool yet exists for Slovene, and even the new orthographic manual anticipates that all transliteration should be done manually, which begs the question whether at least part of the work can be automatized. This would be an important step in the development of a modern, digital infrastructure for Slovene orthography, and would facilitate the automatic expansion of modern digital dictionary databases and datasets for automatic speech recognition.

In addition, although our preliminary experiments with LLMs (ChatGPT 3.5 and 4.0) classifying *Slovene G2P* and *Other G2P* lemmas have yielded much worse results than the best performing LinearSVC model, more systematic experiments are warranted.

As part of our future work, we intend to implement the model into *Pregibalnik*,[12] which is used for automatically extending the lexicon and currently assigns no pronunciation type. The model itself is available under the Apache 2.0 license on Github[13], while the pronunciation type annotations will be included in future versions of Sloleks and, eventually, manually validated.

Acknowledgements

The research presented in this paper was conducted within the research project titled *Basic Research for the Development of Spoken Language Resources and Speech Technologies for the Slovenian Language* (J7-4642), the research programme *Language Resources and Technologies for Slovene* (P6-0411), and the CLARIN.SI research infrastructure, all funded by the Slovenian Research and Innovation Agency (ARIS). The author also thanks the anonymous reviewers for their constructive comments.

Abstract

Bibliographic databases only provide basic services to users, but they could provide much richer information for specific user needs. The main reason for the delay in developing such higher-order bibliographic services is the limited access to data in proprietary databases. We expect the new open bibliographic databases like OpenAlex will encourage faster development of these services. We describe an approach based on a collection of bibliographic networks as a foundation to support the development of higher-order bibliographic services.

Keywords

bibliographic database, open access, network analysis, higher-order bibliographic service, prototype, OpenAlex

1 Introduction

From special bibliographies (BibTEX, EndNote) and bibliographic databases, it is possible to obtain data about works (papers, books, reports, etc.) on selected topics. A typical work description contains the following data: authors; title; publisher/journal; publication year and pages. In some sources, additional data are available including languages, classification of documents, keywords, authors' institution/country affiliation, lists of references, and the abstract. This data can be transformed into a collection of compatible two-mode networks on selected topics [5]: works × authors; works × keywords; works × countries, and other pairs of characteristics describing works. Besides these networks, we can also get the partition of works by their publication years, the partition of works by journals or publishers, the vector of the number of pages, and, in some cases, the (one-mode works × works) citation network.

When constructing any of these networks, the first task is to specify the nodes and which relations are linking them. In short, the network boundary problem [16] has to be solved. This includes deciding whether a network is one-mode or two-mode and which node properties are important for the intended analyses. For specifying links, this amounts to answering a series of questions:

(1) Are the links directed?
(2) Are there different types of links (relations) to include?
(3) Can a pair of nodes be linked with multiple links?
(4) What are the weights on the links?
(5) Is the network static, or is it changing through time?

Another problem that often occurs when defining the set of nodes is the identification of nodes. The unit corresponding to a node can have different names (synonymy), or the same name can denote different units (homonymy or ambiguity). For example in the BibTEX bibliography from the Computational Geometry Database [14] the same author appears under 7 different names: R.S. Drysdale, Robert L. Drysdale, Robert L. Scot Drysdale, R.L. Drysdale, S. Drysdale, R. Drysdale, and R.L.S. Drysdale. Insider information is needed to decide that Otfried Schwarzkopf and Otfried Cheong are the same person. At the other extreme, there are at least 57 different mathematicians with the name Wang, and Li in the MathSciNet Database [20]. Its editors have tried hard, from 1985, to resolve the identification of the author's problem during the data-entry phase. The significant growth of contributions by Chinese scientists and their full name similarity in

Roman transcriptions adds additional complexity to the problem. In the future, the problem could be eliminated by implementing initiatives such as using ORCID or resolving the identification problem in bibliographic databases (Scopus, OpenAlex).

2 Higher-Order Bibliographic Services

The data collected in different bibliographic databases can be used to provide higher-order bibliographic and bibliometric services such as what to read (contact/visit)? – a list of relevant articles/books (authors, institutions) on selected topic; where to publish? – a list of journals suitable for the publication of an article, automatic suggestion of keywords; reviewer selection – a list of reviewers suitable for a submitted article; possible partners for research collaboration; a career application – a candidate's activity report draft; etc.) for different types of users (students, researchers, teachers, decision-makers, funding agencies, research institutions, database managers, etc. . To support this goal we have to use high-quality data often obtained by combining data from different databases.

For the development of higher-order bibliographic and bibliometric services, open bibliographic databases such as OpenAlex are particularly welcome, as the developed services can remain open.

3 OpenAlex

The basic type of unit in a bibliographic database is the work. A user searching the database gets a list of works satisfying the query. Usually, some operations with such lists (inspection, filtering, merging, intersection, statistics, etc.) are supported. Only basic services are provided to users.

Some web services also supporting some other types of units (authors, institutions, research fields, conferences, etc.) were developed such as Google Scholar [19], Scholar GPS [12], and DBLP – computer science bibliography [10].

Our approach is based on OpenAlex [18, 9] but this information can be obtained from most bibliographic databases [13, 11]. OpenAlex indexes more than twice as many scholarly works as the leading proprietary products and the entirety of the knowledge graph and its source code are openly licensed and freely available through data snapshots, an easy-to-use API, and a nascent user interface.

OpenAlex is based on 7 types of units (entities): **W**(ork), **A**(uthor), **S**(ource), **I**(nstitution), **C**(oncept), **P**(ublisher), or **F**(under) (and some additional ones such as topics, keywords, countries, continents, languages, etc.). Each unit gets its OpenAlex ID – we assume that the identification problem is solved by the database.

The simplest use of OpenAlex is through its web interface (service) https://openalex.org/ or using a direct URL request in the browser URL line. For example

- Author's name: search the OpenAlex web service
- Known author ID: URL https://openalex.org/A5001676164
- Work with DOI: URL https://api.openalex.org/works/https://doi.org/10.1007/s11192-012-0940-1
- Known work ID: URL https://openalex.org/W2083084326
- Name of the institution: search the Openalex Web service
- Known institution ID: URL https://openalex.org/institutions/I4210106342

This way, the OpenAlex web interface provides basic inspections of the selected unit. For example, by including a link with our OpenAlex author ID on our web page we get a report on our publications. Similarly, we get the report on the publication activity of the selected institution.

3.1 API

An application programming interface (API) is a way for two or more computer programs or components to communicate with each other. It is a type of software interface, offering a service to other pieces of software [21]. In our case, API enables us to use the database data from our programs. An R package supporting the use of OpenAlex is `openalexR` [1].

The OpenAlex API is available at https://api.openalex.org. Its response is returned in JSON format. Here is an R code using the OpenAlex API for the IMFM institution search

```
setwd(wdir <- "C:/work/OpenAlex/API")
library(httr); library(jsonlite)
res <- GET("https://api.openalex.org/institutions",
    query = list(search="imfm"))
str(res)
cont <- fromJSON(rawToChar(res$content))
names(cont); str(cont)
```

The response data are available in the variable `cont`. Similarly, the API can be used also from other programming languages.

The OpenAlex query can be composed of different components. Using **search** we can search for a given search text across titles, abstracts, and full-text. Using a **filter** we can limit our search to units satisfying given conditions. Using **select** we can select data fields that will appear in results. The query can be further controlled by some parameters. For example

```
wd <- GET("https://api.openalex.org/works",
  query = list(
    search="handball",
    filter="publication_year:2015",
    select="id,title",
    page="2", per_page="200"))
names(wd)
wc <- fromJSON(rawToChar(wd$content)); names(wc)
names(wc$meta); wc$meta$count; str(wc$results)
```

returns the second page (with up to 200 entries) on works on handball published in the year 2015. Only information about works ID and title is returned.

The OpenAlex API uses paging – the list data are provided by pages. The **basic paging** (up to 10 000 units) is based on two parameters `page` and `per_page`). The **cursor paging** is a bit more complicated than basic paging, but it allows us to access as many records as we like.

4 A collection of bibliographic networks

We developed an R package `OpenAlex2Pajek` to support the creation of bibliographic networks from OpenAlex [4]. We get a collection of bibliographic networks (citation network **Cite**, authorship network **WA**, sources network **WJ**, keywords network **WK**, countries network **WC**), some partitions and vectors (properties of nodes) (publication year, type of publication, language of publication, cited by count, countries distinct count, referenced works, and additionally two files containing names of works `xyzW.nam` and names of authors `xyzA.nam`. Most acquired networks are 2-mode – they link units of two different types; an ordinary or 1-mode network links units of the same type.

Currently, `OpenAlex2Pajek` contains three main functions `OpenAlex2PajekCite`, `OpenAlex2PajekAll`, and `coAuthorship`.

We split the process of creating the collection of bibliographic networks into two parts:

- determining the set W of relevant works using the **saturation approach** [7, page 506],
- creation of the network collection for the works from W.

The set W is determined iteratively using the function `OpenAlex-2PajekCite` and the collection is finally created using the function `OpenAlex2PajekAll`.

The function `coAuthorship` creates a weighted temporal network describing the co-authorship between world countries in selected time intervals. The weight of an edge is the number of works co-authored by authors from the linked countries.

In an analysis of weighted networks, the 1-neighbor skeleton is often used to get an overall insight into the network's basic structure. In the 1-neighbor skeleton, only its strongest link is kept for each node. The resulting directed network is forest-like. Non-trivial connected components in 1-neighbor skeletons are (usually) directed trees with a pair of nodes linked in both directions with the largest weight in the tree – these two arcs are usually replaced by an edge (undirected link). In Figure 2 the 1-neighbor skeletons for years 1990, 1995, 2000, 2010, 2015, and 2020 are presented. We see that the number of isolated nodes (countries not collaborating with other countries) is decreasing. In all analyzed years the US has a leading (hub) position. In the years 1990, 1995, 2000, and 2010 the edge in the main component links US and GB but in the years 2015 and 2020 GB is replaced by CN. In 1990, stronger secondary hubs were GB, FR, RU, JP, and DE. In the following years, some other countries SE, ES, AU, CN, BR, ZA, and IN (BRICS) became secondary hubs attracting previously non collaborating countries or geographically or linguistically close countries.

Most of the ingredients of basic reports are counters, sorted lists, (weighted) degrees and their distributions obtained from an adequate network. Sometimes also the time is considered producing time series.

An important property of a collection of bibliographic networks is that some of them are compatible – they share a common set (most often the set of works W). This allows us to use network multiplication (defined by the product of network matrices) to compute the corresponding derived network connecting the remaining two sets [5]. For example, in the derived network $\mathbf{AK} = \mathbf{WA}^T \cdot \mathbf{WK}$ its entry $AK[a,k]$ tells us in how many works the author a used the keyword k. Similarly, in the derived network $\mathbf{ACiK} = \mathbf{WA}^T \cdot \mathbf{Cite} \cdot \mathbf{WK}$ its entry $ACiK[a,k]$ tells us how many times the author a cited works described by the keyword k.

A 2-mode network is always compatible with its transpose (on both sets). The corresponding derived networks are called projections – the row projection $\mathrm{row}(\mathbf{WA}) = \mathbf{WA} \cdot \mathbf{WA}^T$ and the column projection $\mathrm{col}(\mathbf{WA}) = \mathbf{WA}^T \cdot \mathbf{WA}$. Both projections are ordinary weighted 1-mode networks that can be analyzed using standard network analysis methods.

For the authorship network **WA** its column projection $\mathbf{Co} = \mathbf{WA}^T \cdot \mathbf{WA}$ is the co-authorship network. Its entry $Co[a,b]$ counts the number of works that authors a and b co-authored. It turns out that a work with k co-authors contributes k^2 links to the co-authorship network – works with a large number of co-authors are overrepresented in it. To treat all authors equally the fractional approach is used [3]. In Figure 1 the largest co-authorship groups at level 10 at the University of Primorska are presented – connected components of the link cut at level 10 in the network **Co**. Each pair of linked authors co-authored at least 10 works

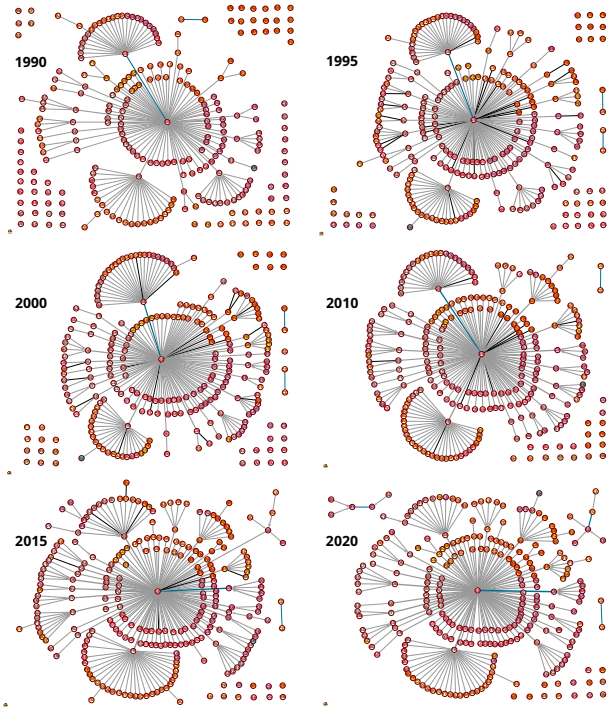

Figure 2: 1-neighbors skeletons of world co-authorship for selected years.

in the bibliography of works with at least one co-author from University of Primorska.

In bibliometric analysis, the citation network **Cite** has a very important role. It collects "votes" about the relevance of previous works for a given work. It is often used for solving the network boundary problem, and also for identifying the most relevant works in the collected bibliography [2, 6]. The derived network $\mathbf{ACiA} = \mathbf{WA}^T \cdot \mathbf{Cite} \cdot \mathbf{WA}$ describes the citations between authors – its entry $ACiA[a,b]$ counts the number of times author a cited author b. The co-citation network is defined as the column projection of the citation network $\mathbf{coCi} = \mathrm{col}(\mathbf{Ci}) = \mathbf{Ci}^T \cdot \mathbf{Ci}$ and the bibliographic coupling network is defined as the row projection of the citation network $\mathbf{biCo} = \mathrm{row}(\mathbf{Ci}) = \mathbf{Ci} \cdot \mathbf{Ci}^T$.

The idea of derived networks can be extended to temporal bibliographic networks [8]. Using derived networks we enlarge the source for different statistics. Additional insight can be gained by analyzing the structure of networks and identifying important subnetworks in them [6].

In the following, we present an overview of typical report ingredients [7, 15]. Because of limited available space, we decided to put examples on Github/bavla.

5 Report ingredients

5.1 Statistics

Because the analyzed networks are often large a complete presentation is not an option. To describe them we use different statistical descriptors.

- sizes of sets (number of nodes, number of links); structural network properties (number of components, size of the largest component, etc.)
- top units – ordered lists of units with the largest values of selected property (degre, weighted degree, link weight,

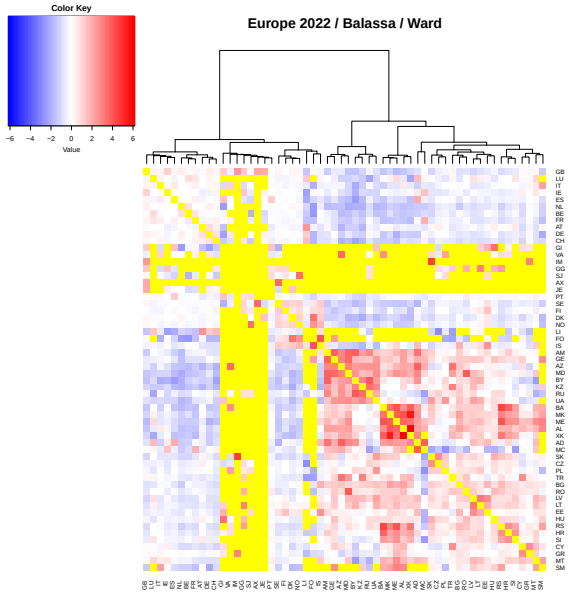

Figure 3: Balassa EU co-authorship for the year 2022.

- distribution of selected property
- time series describing temporal changes of selected properties
- scatter plots showing a possible relationship between two selected properties

Often bibliometric properties of units follow laws such as Zipf (or power) law, Bradford law, Lotka law, lognormal distribution, Hirsch index, etc.

5.2 Network analysis

Derived networks are weighted. To get readable results of reasonable size we usually search for important subnetworks, often a kind of skeleton – from a given network less important elements are removed. There are different types of skeletons (spanning forest, k closest neighbors, cuts, cores, islands, etc. [6]).

A traditional graph-based visualization is used if the obtained result network is not dense. For denser networks, the matrix display is much more readable. In a matrix display, the permutation of nodes (usually obtained by clustering) can create patterns that reveal the network's internal structure.

Figure 3 presents a matrix display of Balassa co-authorship indices between European countries in 2022 (yellow cell – no link, red/blue cell – above/below expectation) [17].

5.3 Special algorithms

Some properties can require special computational procedures and direct access to the bibliographic data. In such cases, open access to the bibliographic database is of crucial importance.

5.4 Reports

The results of analyses can be combined and presented to users in different forms:

- Booklet report (in PDF).
- (Service generated) web pages.
- Dashboards.
- Dataset (JSON, CSV, etc.).

6 Conclusions

We have presented an approach to support higher-order bibliographic services based on networks. Open access to high-quality bibliographic data is crucial for the faster development of such services. The new bibliographic database OpenAlex seems to be a step in the right direction. It needs the support of science policy and also of individual scientists (checking the correctness of their data).

Acknowledgements

The computational work reported in this paper was performed using a collection of R functions OpenAlex2Pajek and the program Pajek for analysis of large networks. Code, data, and figures are available on Github/Bavla/OpenAlex.

VB's work is partly supported by the Slovenian Research Agency ARIS (research program P1-0294, research program CogniCom (0013103) at the University of Primorska, and research projects J1-2481, J5-2557, and J5-4596), and prepared within the framework of the COST action CA21163 (HiTEc). JP's work is partly supported by ARIS (research program P5-0361 and research projects J1-2551 and J5-4596). TP's work is partly supported by ARIS (research program P1-0294 and research projects N1-0140, J1-2481, J5-4596).

Abstract

We conduct a bibliometric analysis of the Slovenian science by scraping the data from Slovenian current research information system (SICRIS) and using it to build a knowledge graph, representing a network of all Slovenian scientific fields and a large majority of Slovenian researchers. By analyzing this network using different graph measures, we obtain valuable insights into the connections between different scientific fields and researchers in Slovenian science. Additionally, we show the importance of graph measures as measures of scientific excellence, since they measure very different aspects of scientific success than the traditional citation metrics.

Keywords

bibliometrics, Slovenian scientific community, knowledge graphs

1 Introduction

With the growth and diversification of the scientific enterprise, obtaining empirical evidence on the research process is crucial for enhancing its efficiency and reliability. Meta-research and bibliometrics are developing scientific disciplines, seeking to analyse, evaluate and refine research practices, and several studies have focused on the analysis of the global scientific endeavour, e.g., identifying most prominent scientists and fields [7]. These studies also focus on the problem of how to properly rank scientific excellence and scientific outputs in general, warning that one should not rely on just a few metrics to obtain a comprehensive picture of the actual impact a specific scientist has [8].

Until now, very few studies have tackled the analysis of scientific ventures at national level, and to our knowledge, there has been no study covering the Slovenian scientific landscape specifically. This kind of research is nevertheless important and could potentially influence policies that would improve scientific production and enable effective distribution of research funds and resources.

In this study, we try to address the identified research gaps by 1.) drawing the map of Slovenian scientific research that would enable proper decision making and policy formulation, and 2.) proposing new metrics of scientific excellence that would allow us to obtain a more complete view of the impact a scientist or a discipline as a whole has. More specifically, our contributions are the following:

- Using the collected data about the Slovenian scientists and their projects, covering different scientific fields and a large majority of researchers working in Slovenian science, we conduct a graph analysis of connections between different fields and researchers. By drawing a comprehensive map of connections between actors and fields, we identify the most important researchers and scientific fields that connect others and play a vital role in the Slovenian scientific ecosystem.
- We created a new ranked list of Slovenian scientists according to graph based metrics, which were not available in any of the previous analyses or databases. We argue that these metrics measure the importance of a role that a specific scientist has in a research community, i.e., their influence which allows them to act as a bridge or a hub connecting scientists from different fields.

2 Related work

Studies in bibliometrics (see [4] for a comprehensive survey of techniques used for measuring scientific excellence) have recently gained traction in parallel with the success of the scientific enterprise, which has grown in both size and diversity, and with the availability of data. According to Ioannidis et al. [7], research on research is becoming important due to the mounting evidence suggesting an alarming drop in reproducibility of research findings, the growing inefficiency of the scientific process, and the fact that the number of false positives in the literature is exceedingly high. To address these problems, they propose a meta-research divided into five main categories that should be studied: methods, reporting, reproducibility, evaluation, and incentives. Studying these five areas would correspondingly allow for five distinct insights into how to perform, communicate, verify, evaluate, and reward research.

Recently, several studies also tackled the problem of how to properly rank scientist and scientific outputs in general. For example, Ioannidis et al. [8] addressed the increasing prevalence of multiauthorship observed in several fields and how this phenomenon affects the effectiveness of the informativeness of citation metrics. They also explored how sensitive the indicators are to self-citation and alphabetic ordering of authors. They concluded that multiple indicators should be used for ranking, as a composite of different metrics gives a more comprehensive picture of the actual impact that a specific scientist has. They also acknowledged that no single or composite citation indicator can be expected to select all the best scientists.

Several studies employed graph-based metrics to enrich the assessment of bibliometric analysis [4, 1]. Network metrics such as degree of centrality, betweenness centrality, eigenvector centrality, closeness centrality, and PageRank were used to pinpoint the relative importance of research constituents (i.e., researchers and institution), which may not necessarily be reflected just through publications. In a large majority of cases, these metrics were calculated on co-authorship graphs.

The studies that would cover Slovenian scientific environment are very scarce. In fact, we are aware of just one, the study by [2], where they claim that research performance is highly dependent on the conditions of (national) research environments. They focus on analyzing research activity in six eastern European countries, namely Croatia, Estonia, Hungary, Latvia, Lithuania, and Slovenia, and try to determine and compare the effectiveness of research in a specific country by obtaining the number of articles belonging to the most cited 10% and the most cited 1% articles in the corresponding subject area and publication year for each country. Their empirical analysis addresses three levels: cross-country, cross-institution, and cross-researcher comparison. The study concludes that Hungary is the country with the highest output, followed by Croatia and then Slovenia, when it comes to the number of influential articles published.

3 Methodology

In this section, we describe our methodology, namely 1.) how we gather the data and 2.) how we analyze these data to obtain a map of the Slovenian scientific community.

3.1 Data Retrieval

Data were retrieved from the Slovenian Current Research Information System (SICRIS) website[1], which lists more than 35,000 researchers working in Slovenian research institutions. Data collection from the SICRIS website proved challenging, as information about a specific researcher can only be obtained by scraping his/her Web page on SICRIS. This required finding a solution to quickly retrieve data from more than 35,000 different pages, and to achieve this, we used the Python Asyncio[2] and BeautifulSoup[3] libraries, which allow the asynchronous connection to several dozen pages simultaneously and extraction of the required data.

Since the script sometimes took several seconds to connect to a specific page, which could quickly accumulate, resulting in considerable overall slowdowns, we optimized the procedure and identified potential slowdowns. Our proposed solution was to implement a strategy that involved canceling the connection and adding the URL to a list whenever a page failed to connect within a 0.5-second time frame. This timeframe was chosen after several trials and was found to be the best compromise. Once all pages had been visited, we repeatedly tried to reconnect to the URLs on this list until it was empty. This change significantly reduced the time required to retrieve all our data. Once all the data was retrieved, we used the Pandas library[2] for data manipulation, which allowed us to export the results into Excel spreadsheets, appropriate for further processing.

From SICRIS, we extracted research areas for each scientist and various bibliometric indicators of their impact, namely A", A', A1/2, citation metrics based on a quantitative assessment of publications in exceptional, high quality and important venues, respectively. We also extracted the A1 metric, which represents a weighted sum of these three metrics, a CI10 metric measuring the number of pure citations of scientific work in the last 10 years, the CImax metric measuring the number of citations in the most cited work, and the h10 metric representing the h-index in the last ten years. Furthermore, we extracted the SICRIS points, a conglomerate metric combing several distinct metrics mentioned above, and the A3 metric, which measures the amount of funds a specific researcher received for his research activity outside of the Slovenian National Research Agency (ARIS).

Finally, the SICRIS database also contains information on projects financed by the Slovenian national research agency in which a specific researcher participated. Scraping this information provided us with an important insight into collaborations between different scientists and fields, allowing us to build collaboration graphs, calculate several graph-based ranking criteria and draw the map of the Slovenian scientific community.

3.2 Methods

Once the data was obtained, we conduct two distinct analysis steps, namely 1.) graph construction and analysis, and 2.) correlation analysis

3.2.1 Graph construction and analysis. To construct the necessary graphs, we used the Python NetworkX library [6]. Using the data from SICRIS, which contain information about project collaboration, we created an undirected graph as follows: all researchers who participated in at least one project are represented by a node, and nodes of researchers who worked together on a project are connected by weighted edges, in which the weights represent the number of shared projects. By removing the isolated nodes, we ended up with a graph with a total of 20,012 nodes and 618,871 edges.

In the next step, we apply several graph statistics and measures in order to obtain several node rankings, each of them measuring a different aspect of the importance a specific node (i.e., a researcher) has in the graph. More specifically, we calculate PageRank (PR), Betweenness centrality (BC), and Eigenvector centrality (EC) measures.

In the context of our graph, the **PageRank** [3] algorithm is applied to evaluate the influence of researchers within the collaboration network. Thus, researchers who are strongly connected to other researchers, who also have many connections (i.e, the so-called hubs in the graph), will have a higher PR score, reflecting their importance and influence in the Slovenian research community. On the other hand, the **Betweenness Centrality** [5] measure evaluates the role of each researcher as an intermediary or a bridge between other researchers. This measure is based on the idea that researchers who are on many collaboration paths between other researchers are considered central and influential in the network. In our contexts, it helps to better understand the structure of the collaboration network among researchers. Researchers with high BC are those who play a crucial role in creating links between different subgroups of researchers and interdisciplinary connections. In practical terms, BC evaluates the number of times a researcher is traversed by the shortest paths connecting other researchers in the network. Thus, researchers who are frequently used as pathways for collaboration among their peers obtain higher BC scores.

[2] https://docs.python.org/3/library/asyncio.html
[3] https://www.crummy.com/software/BeautifulSoup
[2] https://pandas.pydata.org/

[1] https://networkx.org/

Another graph centrality measure that we applied to the created graph is the **Eigenvector centrality** [9]. This measure evaluates the influence of a researcher taking into account both the quality and the quantity of connections. EC assigns more weight to connections that include influential researchers. Thus, a researcher connected to influential researchers will be assigned a high score, reflecting potentially greater influence within the network. This measure helps to detect researchers who, even with fewer direct connections, occupy strategic positions in the collaboration network. While this may seem similar to the PR algorithm, there are some differences. Unlike PR, which primarily focuses on the popularity of links, Eigenvector centrality also takes into account the quality of connections. This means that even if a researcher does not have a large number of direct connections, if they are connected to influential researchers, their Eigenvector centrality score can be high. In summary, while both measures aim to evaluate the influence of researchers in a network, they do so through slightly different approaches, thus offering complementary perspectives for analyzing the structure and importance of actors within the collaboration network.

Our second important area of focus in our research is the collaboration between different fields. To build a graph that would represent interdisciplinary collaboration between fields, we grouped all researchers from the same field into a single node, representing an entire field, i.e., we obtain a node for each scientific field found on SICRIS. Similar to the previous graph, edges and their weights represent collaborations on a project between researchers in the linked fields.

3.2.2 Correlation analysis. In order to better understand the metrics from SICRIS and to evaluate the relevance of our scores, we deemed it pertinent to explore the correlation between all our data. This analysis has two main purposes. First, we aim to test the **hypothesis 1** that the new graph ranking we presented, measure different aspects of scientific excellence than the more established measures based on number of citations or publications available on the SICRIS web page. This hypothesis would be deemed correct if one-on-one correlations scores between the newly proposed graph measures and other measures would be low, and incorrect if correlations would be high.

Additionally, we wish to explore the correlation between the established measures available on the SICRIS web page. More specifically, we wish to test the **hypothesis 2** that these measures are strongly correlated, which would indicate that they essentially all measure a very similar aspect of scientific excellence, which is problematic. In order to obtain one-on-one correlations between all measures, we calculate the Spearman correlation coefficient among all of them and then display it through a heatmap.

4 Results

In Table 1, we present some of the results of the graph analysis conducted on the graph of nodes representing researchers, connected by edges representing project collaborations. More specifically, we present 10 best ranked researchers in the SICRIS dataset according to the average between ranks of the three newly proposed graph-based measures, their declared scientific fields, and their ranking (i.e., lower is better) according to the SICRIS points, BC, EC and PR measures.

Note that while the table does contain some highly ranked researchers according to the SICRIS points (e.g., Dr. Sašo Džeroski is ranked as 33rd out of roughly 20K researchers according to this criteria), several researchers in the table are ranked relatively low according to SICRIS points (e.g., the best ranked researcher according to our novel three measures, Dr. Branimir Leskošek, is ranked as 5731th according to the SICRIS points). This finding supports **hypothesis 1** that the proposed new measures measure different aspects of scientific excellence than the more established citation measures. Another important observation is that 7 out of 10 best ranked scientists appear to be active in two fields. This might suggest that they are (or have been) involved in several interdisciplinary projects, which could have a positive influence on the newly proposed graph-based metrics.

In Figure 1, we present the heatmap of the correlations between the different metrics extracted from SICRIS website and the newly proposed graph-based metrics. We observe a strong correlation between PR and BC, 0.7, which might suggest that researchers who collaborate with a wide range of colleagues from different fields are more likely to work with the most important ones.

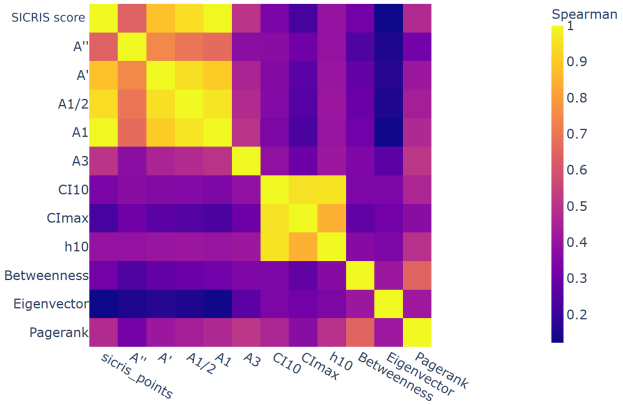

Figure 1: Heatmap of the Spearman correlation among metrics.

We also observe very strong correlations in the top left corner of the heatmap. While a strong correlation was expected, as A", A', A1/2 and A1 are all scores based on the number of publications (in venues of different qualities), the almost perfec correlation between the SICRIS points and A1 (which suggest they measure exactly the same aspect of the scientific impact) is surprising. This finding supports **hypothesis 2** that the current SICRIS measures all measure a very similar aspect of scientific excellence. On the other hand, there is no strong correlation between any of the newly proposed graph-based metrics and metrics extracted from the SICRIS website.

In Table 2, we present the results of our study of interdisciplinary collaboration between different scientific fields. The graph metrics were obtained from a graph of nodes representing fields and edges representing interdisciplinary project collaborations. Note that the field of Computer science and informatics ranks first according to all the criteria. On the other hand, most interdisciplinary collaborations are conducted by the researchers from the field of Chemistry, which ranked as third according to the average (AVG) between the ranks of three graph-based metrics, PG, BC and EV.

5 Conclusions

The graph based bibliometric analysis of the Slovenian scientific community shows that current citations based metrics do not cover some aspects of scientific excellence, such as researcher's

Table 1: 10 best ranked researchers in the SICRIS dataset according to the average between ranks of the three newly proposed measures, BC, EC and PR. We do not show metric scores, but ranks according to scores (i.e., lower value is better).

role of connecting a wider research community. Our correlation analysis indicates that existing measures of scientific excellence extracted from the SICRIS web page are strongly correlated. In the future, we plan to expand this analysis to also measure the impact of Slovenian scientists on the global scientific enterprise and conduct additional research to try to find certain patterns across disciplines, or institutions.

6 Acknowledgments

The authors acknowledge the financial support from the Slovenian Research Agency for research core funding for the programmes Knowledge Technologies (No. P2-0103).

ABSTRACT

The amount and heterogeneity of data generated in the context of education allied to the rapid progress of scientific research and technological development have created vast amounts of data, much of it open data, but significant challenges to gathering, filtering and making sense of this information. In this paper, we discuss the research outcomes of complementary Artificial Intelligence (AI)-based strategies monitoring and enhancing Open Education, mining online forum interaction student-educator, and empowering mentorship of educators. Firstly, the initial results obtained from the construction of an Observatory focusing Open Education Resources (OERs), contribute to implement 2019 UNESCO OER Recommendation and advance the Education-focused Sustainable Development Goal (SDG) 4. It is acting on five verticals, enriching and treating multilingual data, it displays meaningful information on a dashboard focused on AI and OERs and serving as a collaboration platform focused on existing partnerships within the international research centre on AI under the auspices of UNESCO (IRCAI), the UNESCO Chair in Distance Education and the UNESCO Chair on Open Technologies for Open Educational Resources and Open Learning, mobilizing research collaboration on key AI research challenges relating to generating knowledge about OER. Secondly, we will discuss the recent development of an Educational Recommender System (ERS) that integrates Conversational Analysis (CA) to assess and enhance collaborative learning (CL) in Virtual Learning Environments (VLEs). This novel system was designed to identify collaboration among students and provide tailored recommendations to promote participation and interaction within discussion forums. Finally, we will discuss the development and implementation of AI and OERs in alignment with SDGs, addressing topics of significant social impact over an international online mentoring initiative.

1 Introduction

The centralizing piece of the discussions in this paper is an AI-based observatory that allows to explore OER-related topics, particularly those mentioned in the OER Recommendation: promoting OER and acknowledging it's contribution to advancing quality education while providing information on advances focused on the equity and inclusion qualities of OER, as well as on research, activities, projects and news related to OER development, including new initiatives and projects while also promoting public infrastructures for education. The OER Observatory builds on the content made available in UNESCO's OER Dynamic Coalition Portal (oerdynamiccoalition.org) providing the user with access to any of the four proposed views: media; science; policies and training. In each of the views, the user can access interactive data visualisation summarising the sourced data configured to observe the UNESCO OER recommendations. As it is fully based on open data, it allows the user to click on the resources collected and summarized, being taken directly to the source in media, journal, policy or training.

Embracing the intersection of AI and education, which has led to the development of various tools that personalize and enhance learning experiences, we discuss a complementary research based on CA much aligned with the objective of empowering Community interaction at the SDG 4 (Education) Observatory [6]. AI applications in education often focus on providing adaptive feedback, facilitating personalized learning paths, and analyzing student data to improve outcomes. CA is a method that examines the understanding generated through interactions, offering a framework for analyzing how students collaboratively build knowledge. By combining CA with AI, this research aims to develop a system that not only assesses but also actively promotes collaboration in VLEs [10]. The ERS discussed later in this paper, is an example of how IRCAI's SDG4 Observatory gains a complex capability towards the engagement with communities such as in Education. This discussion then expands towards the appropriate mentorship of the professionals that will change the domain's landscape. While initiatives in this context are diverse and disperse, the authors are not aware of existing similar approaches [5].

2 AI-based strategies for the moderation of online forums on education

Entering the age of Big Data, AI is feeding the data-driven digital transformation across industries including Education. CL emphasizes the importance of group tasks and joint participation, wherein students learn by actively engaging in dialogues that facilitate the sharing of ideas and information. Even in remote settings, CL enables students to learn together through virtual platforms. AI offers new opportunities as a pedagogical tool, providing adaptive and personalized environments that can support CL. This research explores the integration of AI into educational contexts, particularly through the development of an Educational Recommender System (ERS) that uses CA to identify and promote collaboration among students in VLEs [1] (see Figure 1).

Figure 1: The ERS forum analysis screen

The research methodology is divided into three key stages: *Conversational Analysis*, applying CA to monitor discussion forums within the Moodle platform, focusing on interactions among students, identifying collaborative behaviors and interaction patterns; *Collaboration Assessment***,** evaluating the level of collaboration among students based on identified interaction patterns; and *Development of ERS*, building a mechanism that provides recommendations to students, teachers, and tutors. These recommendations are aimed at enhancing collaboration and are based on the analysis of forum interactions [15]. The initial dataset comprises 20,976 messages of Moodle discussion forums, with 15,703 posted by students from a vocational education school. The analysis focuses on these messages to develop and validate the ERS's recommendations. The quality of collaboration is measured through various indicators, which are extracted during different stages of CA. *Preprocessing* applies techniques of Natural Language Processing (NLP) to ensure the accuracy of the analysis, preparing data for the *Resource Processing* stage using Social Network Analysis (SNA) to characterize social dynamics and interactions among students. Moreover, the *Message Attribute Identification* is the CA stage that allows identifying characteristics of students' messages, , specifically their questions, and then *Topic Modeling* is employed to identify key terms discussed in the forums [12], using Tomotopy library (bab2min.github.io/tomotopy) The ERS was tested across five experimental cycles in different classes at two Brazilian Federal Institutes , in a Portuguese language context. The results indicated a positive impact on student learning, with 82% of participants acknowledging the relevance of the recommendations. The system motivated increased participation and collaboration, with a notable trend of students writing more and systematically organizing their ideas in forum posts. Additionally, 90% of students engaged in other activities proposed by their teachers, demonstrating the effectiveness of the recommendations. The results also demonstrate the system's effectiveness in fostering collaboration, with positive feedback from students and educators. A dashboard was developed for teachers, containing graphs including one that shows the main terms discussed in the forum by analysis, in which each edge represents a message from the student with two of these terms, and the nodes in blue highlight the new terms that emerged in relation to the previous analysis (see Figure 2).

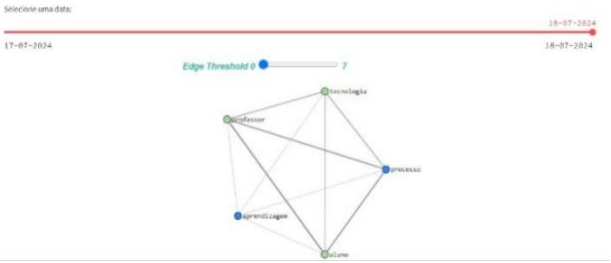

Figure 2: Visual analysis of students' collaboration in a discussion forum where nodes represent actors in the discussion (students/educators) and edges represent interactions.

The development of the ERS represents a significant advancement in promoting collaborative learning in educational settings [6,7]. By integrating CA into the system, the ERS effectively identifies and enhances collaboration among students. The current implementation of this ERS aims to provide personalized recommendations to students, teachers, and tutors, fostering a more interactive and collaborative learning environment [6]. Future work will explore the integration of additional features, such as *wikification* and visualization tools, to further enhance the system's capabilities. Furthermore, the research will benefit from the semi-automatic categorization of educational resources of a range of formats, including videos as in [3].

3 An AI-based Observatory to Assess the Impact of OER Worldwide

Although the abundance of information available online, some of which is labeled as education-related, it is harder and harder to find the appropriate resources that can serve education either at an undergraduate or a professional training level. IRCAI's Open Education Observatory is an initiative dedicated to monitoring, analyzing, and promoting the use of OERs globally. It serves as a hub for research insight and fomenting collaboration, providing valuable insights and data on the

adoption, impact, and trends of OER in education systems worldwide. The observatory supports educators, policymakers, and institutions in leveraging open resources to enhance teaching and learning. It is designed to support government and institutional decision-makers dedicated to promoting the goals of the 2019 UNESCO OER Recommendation, which is centred on OER but generally promotes the ideals of Open Education (see Figure 3).

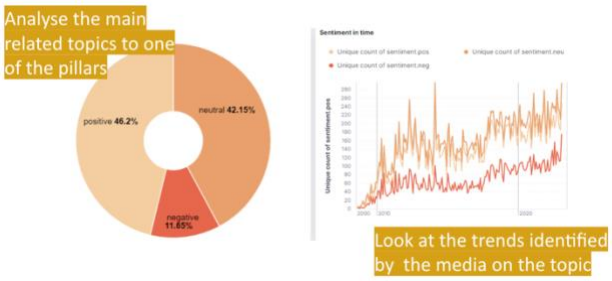

Figure 3: Dashboard of visual modules to analyse the most relevant topics under a certain domain or SDG, and the trends that can direct the education actors preparedness

The Open Education Observatory ingests a range of different data sources with heterogeneous nature and different frequency: (i) worldwide news in almost real-time providing information from a vast catalogue of multilingual world news, captured in more than 60 languages and based on a variety of *wikidata* concepts; (ii) published scientific articles, including journal and conference papers, mostly peer-reviewed, covering over more than 126 million articles with yearly updates; (iii) OER policies from the OER Policy Hub (www.oepolicyhub.org) that needs to be input into the OER DC Portal; subsequent extraction and enrichment of metadata; preparation of dashboard related to dashboard based on filters over the metadata, as well as OECD policies data and metadata on AI and Education with yearly updates; (iv) lectures and videos selected and filtered on content from Videolectures.net [10] resources related to OER; (v) a snippet of worldwide public and private initiatives related to AI and SDG 4 captured by IRCAI's Top100 and related actions; and (iv) a range of worldwide indices with yearly updates on Education-related topics such as the percentage of children out of school, or the literacy rate in youth and adults (see Figure 4).

To ensure that content is readily available for each focus area, materials from the mentioned sources are categorized by relevant keywords and concepts closely associated with the five key areas of the Recommendation. This organization allows users to easily filter and access content based on their specific interests within these areas. By doing so, users can tailor their exploration of resources to match their focus, whether it's capacity building, supportive policy development, leveraging equitable access provided by OER, sustainability models, or international cooperation.

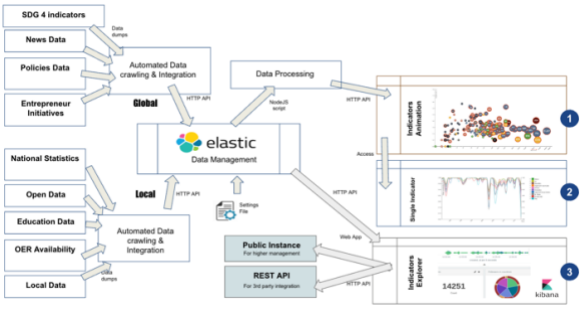

Figure 4: The architecture of the OER Observatory as an Elasticsearch-based system that enables the visualization of heterogeneous data on OERs

For each area, users can filter and find content specific to their domain of interest: up-to-date news and research on OER developments, academic studies related to professional development, and relevant lectures for capacity building; information on OER policy development; resources and research focused on effective, inclusive, and equitable access to quality OER; strategies for developing sustainable OER models; and opportunities for fostering international cooperation through potential new partnerships and shared goals. This organized approach enhances the ability to pinpoint and utilize the most relevant information in each domain. Information generated by the Observatory can be used to aid in the resolution of problems related to the promotion of OER, by identifying trends and major areas of discussion, and to explore successful scenarios through similar challenges and cases. The Observatory provide benefits to a range of stakeholders including: national governments, providing access to a variety of perspectives on OER trends for decision-making; educational and research institutions, facilitating the access to resources and data; civil society, allowing access to information and training materials that explore the knowledge available towards the implementation of the UNESCO recommendations; and the general population, empowering open education.

4 Open Education for a Better World

The Open Education for a Better World (OE4BW) program is an international online mentoring initiative aimed at advancing the development and implementation of open educational resources (OER) that address topics of significant social impact, in alignment with the United Nations Sustainable Development Goals (SDG) [2,14]. As part of the Slo2Svet project, the program received 70 project applications and 87 mentor applications from six continents and 25 different countries (see Figure 5). The program's activities are structured into thematic clusters, focusing on areas such as Artificial Intelligence, Displaced

Persons, Sustainability, Health and Well-being, Renewable Energy, Education, and Youth (specifically targeting developers aged 12-24). Throughout the project development process, progress was closely monitored by a network of mentors and hub coordinators, providing essential guidance and support to OER developers. Additionally, within the scope of the Slo2Svet project, evaluation rubrics for the OER projects were developed and will be utilized during the final conference, where developers will present their completed work.

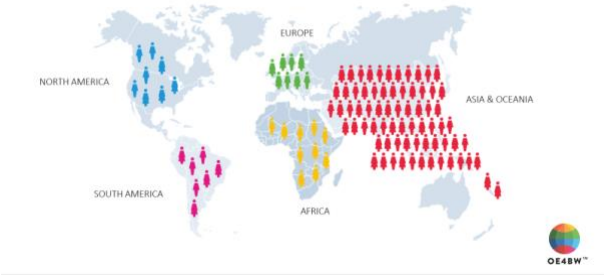

Figure 5: Participants of the OE4BW mentorship in 2023/24.

5 Conclusions and further work

In this paper we discussed the research results and opportunities in Open Education, building on an overall perspective over the OER landscape, the AI-enhanced student-educator interaction, and the mentorship for further progress.

We will be exploring further the potential of the OER observatory, particularly in what regards the appropriate use of LLMs in analyzing the compliance to AI policies in Education. In what regards the future developments of the EduColab, in alignment with IRCAI's *SDG 4 Observatory* and the *Videolectures.net* research agenda and the potential for institutional collaboration, we will focus on: (i) the appropriate *wikification*, incorporating suggestions of *Wikipedia* concepts identified by *Wikifier* and related to the main discussion topics; (ii) integration of interactive data visualization presenting graphical representations of collaboration trajectories, topic evolution, and other key indicators; (iii) extending the system, applying the ERS to other datasets, including public and private message exchange logs, to validate and enhance its applicability; and (iv) personalized recommendations**,** developing a user-based collaborative filtering technique to tailor recommendations more specifically to individual student groups. Moreover, we will explore together the pathways of AI-based citizen science in the context of Open Education and how it can be integrated in the wider scope of the SDG4 Observatory. In the context of the Slo2Svet project, we are conducting a comprehensive analysis of the Open Education for a Better World (OE4BW) mentoring program since its inception, examining outcomes and connections to other initiatives [see for example, 12]. Additionally, we will develop an evaluation framework to assess the impact of the projects produced through the program, mapping project outputs to the five action areas of the 2019 UNESCO OER Recommendation, using insights provided by automatic text analysis and other AI tools. This will allow us to connect the projects produced by OE4BW to the concrete objectives of the Recommendation, providing examples of practice that can be leveraged to advance its goals.

ABSTRACT

The topic of water sustainability has been leading the priorities worldwide where Artificial Intelligence (AI) can position research institutions, public & private companies and governments towards evidence-based decision-making in regards to water resources. In this particular domain, the amount and heterogeneity of data generated allied to the rapid progress of scientific research and technological development have created vast amounts of data, but significant challenges to gathering, filtering, and making sense of this information. This paper presents the research outcomes of collaborative effort engaging a total 51 students mentored by 15 professors across 11 research institutions in North Africa, distributed by 14 selected projects focusing the appropriate application of machine learning methods to local and national water sustainability problems. These outcomes were motivated by a youth challenge co-organized during May 2024 between AI Africa and IRCAI with the support of GITEX.

KEYWORDS

Machine learning, text mining, large language models, community engagement, water sustainability, competition

1 Introduction

Building upon common interests, exciting initiatives and existing projects developed by IRCAI and AI in Africa (aiinafrica.org), focused on AI and Sustainability, this activity aimed to build capacity within African youth to advance the Sustainable Development Goals (SDGs) though AI on challenges within their own communities and in the region. The AI Youth Challenge originated in the context of discussions started in GITEX Dubai in 2023 and forwarded to a concrete event in the AI Everything section of the GITEX Africa in the end of May 2024. It was mostly directed to PhD/MsC students and young entrepreneurs working on AI to solve problems for the good of their communities, exploring a wide range of machine learning methodologies (from image recognition on satellite imagery, to text mining on social media, gamification strategies optimizing water consumption, and application of LLM frameworks for RAG and AI Agents in the context of water sustainability), engaging experts from global agencies like, e.g., UNESCO, AI Movement, and UNESCO's Water Education Institute, as well as national companies, research institutions and government. The global challenge of this action, "Water, AI and Sustainability" is one of the MENA priorities, takes into consideration the UN Water Program for 2024-25 [12], and follows the work done by IRCAI with the European Commission (EC) on the NAIADES Water Observatory [9], as well as the recently opened new IRCAI Committee on AI and Water Resource Management [4] focusing on the impact of AI in SDG 6 [11]. This work aligns with UNESCO's interests in taking action to capacitate the Youth towards AI, with focus on the recent activities based from Morocco but with a global scope, including the opening of the new UNESCO AI Centre, the AI Movement (aim.um6p.ma).

Figure 1: Winner of the AI4Water challenge, designed and developed by UM6P students, exposing a water map that pinpoints remote villages with assigned water scores based on satellite imagery and crowdsourced data.

2 Finalist innovative ideas on water sustainability

Attracting the participation of more than 50 PhD and MsC students across 20 teams based in research institutions in Morocco, this initiative was designed to encourage a conversation between the communities, corporate thought leaders, the education visionaries, and the ecosystems builders to have constructive conversations around the shifts and needs of the changing future landscape. The discussions included researchers, start-up communities, technologists, and government representatives to unite and define the future of water sustainability as they see it. The selected AI technologies and methodologies ranged from the use of satellite imagery to the analysis of news and social media, or the input from water-related sensors and the application of Large Language Models (LLMs) to describe good practices. We shall proceed with describing the problems addressed by the finalists of the AI4Water challenge, their prototypes and the value of the innovation they brought with them.

AquaScore. The Rural communities in Morocco's High Atlas Mountains struggle with water management due to limited resources and visibility. Despite needing modest funds, these villages face significant hurdles in accessing support. The challenge lies in objectively quantifying water issues and connecting these communities with potential supporters. AquaScore creates a water map that pinpoints remote villages and assigns them water scores based on satellite imagery and crowdsourced data. This enables ranking villages by water criticality, helping funders and supporters identify where to direct their assistance effectively. The prototype (described in Figure 1) also offers a platform for discussing water solutions, fostering community engagement through gamification features. By increasing the visibility of rural Moroccan villages and providing objective water criticality assessments, AquaScore facilitates efficient resource allocation for donors and experts. This AI-driven approach ensures fair and unbiased assistance to communities in need, promoting water sustainability and improved water management in constrained environments.

AquaScore employs a hybrid approach combining Computer Vision (CV) and Natural Language Processing (NLP). CV algorithms segment satellite images to generate automated baseline water scores, while NLP algorithms extract insights from textual data to enhance score accuracy. This combination allows for objective assessment and continuous improvement of water criticality rankings. The team has already aggregated data on 1,322 High Atlas villages, extracted satellite images, and segmented them using Facebook's Segment Anything model. This process was completed on UM6P servers using 500GB of storage and 80 CPU cores. The system will incorporate user-submitted reports and internet-scraped data to further refine water scores. The uniqueness of AquaScore lies in its data generation and refinement approach. It creates datasets in areas with data scarcity, starting with an automated baseline from satellite imagery and then enriching it through user-generated content. This closed-loop system employs active learning, progressively enhancing accuracy and relevance of water scores.

AquaSense. Water management is a critical issue in many countries, including Morocco. Severe droughts, poor water distribution, and recent natural disasters raise the urgent need for better solutions to manage water resources effectively. AquaSense's prototype (see Figure 2) offers a smart way to handle water resources by predicting future water situations, visualizing key data, and engaging citizens and communities. This helps decision-makers plan better, save resources, and respond quickly to local water issues. AquaSense provides accurate forecasting of water parameters for informed management and answers water-related questions with detailed analysis using the latest data and news. It offers transparent data visualization through interactive charts, allowing users to view and upload data easily. The community & citizens' space features real-time news updates, a water levels map to locate and help regions in need of water, and a tool to easily report local water issues.

Figure 2: Screenshot of the prototype of Aquasense defining parameters, visualizing data and monitoring engagement.

AquaSense combines two distinct parts of AI: DL (LSTM) and Generative AI (RAG and AI Agents). AquaSense uses Multivariate and multistep LSTMs to accurately predict water parameters' levels for the coming years, and Retrieval-Augmented Generation and AI Agents to answer water-related queries with detailed analysis, using the latest data, news, predicted parameters, and documents from sources like UN, UNCCD, and EPA. AquaSense uses Tensorflow and Keras (LSTM model), Pandas and Numpy (data preparation & mgmt.), Langchain (LLM framework for RAG and AI Agents), Chroma (Vector DB), Nomic Embeddings (Open-Source embeddings), GPT3.5-TURBO (LLM model), Streamlit (Web app). Aquasense improves water management by helping stakeholders make informed decisions, enhancing resource allocation, and promoting sustainable practices. Through its innovative features, it bridges the gap between citizens and authorities, which fosters collaboration and reduces water crises over time. Also, AquaSense aligns with several UN Sustainable Development Goals (SDGs) such as SDG 6 (Clean Water and

Sanitation), SDG 13 (Climate Action), and SDG 11 (Sustainable Cities and Communities).

Water Consumption Tracker. This prototype is addressing the global problem of water optimization in the light of the already visible consequences of climate change. That is, the large amount of wasted water due to irresponsible water use by the households. The added value lies in the behavioral approach: the application is designed to make users more aware of their attitude toward water consumption, and to make water conservation a pleasure rather than a responsibility. Introducing a gamification approach as a new strategy should help make water conservation more appealing. It is based on an app that tracks real-time water usage, provides personalized recommendations, and motivates users over a gamification environment, fostering a community focused on sustainable water use.
The use of Machine Learning models such as Random Forest Regressor to find patterns between the households characteristics and their water usage behavior. We plan to add GenAI using LLM model as a chatbot to support our vision by providing custom tips to optimize water usage. The approach was fundamentally based on: (1) collecting data about the households using our application UI; (2) providing optimum water consumption level by the ML model based on the data collected; and (3) monitoring water usage through IoT sensors and the notification system of our App. The data collected is used to optimize the ML model performance. Our approach can potentially reduce household water waste by 20-50% by educating users about their consumption habits through notifications, ranking systems, and feedback mechanisms.

Figure 3: The pitch of one of the top 3 teams – Ghayt – presenting the Water Consumption Tracker at the AI stage of GITEX Africa.

Aquatic Biodiversity. The introduction of non-native species into marine ecosystems presents a significant threat to the fragile equilibrium of these vital environments. Invasive species, often aggressive, can outcompete native organisms, leading to disrupted food chains, altered habitats, and potentially irreversible ecological harm. From coastal areas to the open sea, the swift proliferation of invasive plants, animals, and microorganisms endangers the biodiversity, productivity, and resilience of our marine life. Addressing this escalating global issue requires immediate and decisive action. AI-powered early detection algorithms were prepared to constantly monitor for signs of invasive species, triggering immediate alerts to enable rapid response. Based on species-specific data, the system can precisely deploy the most effective eradication methods, from underwater drones to selective biocides. As invasive species evolve, the AI-driven platform continuously adapts strategies, ensuring that the interventions remain effective and environmentally responsible.

YAZ. High unemployment rates in North Africa often translate into many individuals employed in low-wage jobs, particularly youth from low-income households. Severe water scarcity leading is decreasing exports and rising prices of vegetables and fruits. Challenges meeting the needs of Morocco's population while being a major exporter of produce to global markets. This AI-based agricultural solution is based on Smart Hydroponic Towers designed to efficiently grow crops vertically indoors and outdoors, offering optimal use of available spaces. The adoption of hydroponics in Africa has the potential to create millions of new jobs in the coming years. Integrated with GPT architecture, the technology allows real-time monitoring, pest detection, and yield estimation. YAZ hydroponics are a shift towards a resilient and sustainable Moroccan agriculture.

The tools and technologies presented in this paper that are open source, are available at IRCAI's SDG Observatory GitHub repository (github.com/IRCAI-SDGobservatory).

3 From concept to prototype in a month

AI in Africa in collaboration with IRCAI conducted a gathering of minds which culminated in a 1-day summit around technologies and shifts of the future, hosted by GITEX in the AI Everything section of the GITEX Africa 2024. Between 26th April and 31st May, 55 PhD and MSc students from 11 research institutions took part of a complete program including expert sessions kicked-off at the AI movement, UNESCO's new center for AI in Africa, and engaging experts in water-related topics such as Matjaž Mikoš, UNESCO chair for landslide risk reduction, droughts and floods, discussing our recent research on news mining for extreme weather events [5, 6]; Gerald Corzo Perez, senior researcher at the UN Water Education IHE Delft, discussing our ongoing research on Water, AI and Twitter [7]; and Ignacio Casals, R&D Manager in Aguas de Alicante Spain, providing a industrial perspective on the use of AI to tackle the challenges of wastewater management [8].
The students were followed across 8 stages including: conceptualization; data collection, analysis and visualization; methodology and implementation, prototype building and pitch (see Figure 3). In order to maximize the impact of the programme, the content from the abovementioned opportunities will be organized across UNESCO's most related to the five areas: (1) capacity building; (2) developing

supportive policy; (3) effective, inclusive and equitable access to quality Education; (4) nurturing and creating sustainability models for Water Sustainability; and fostering and facilitating international cooperation.

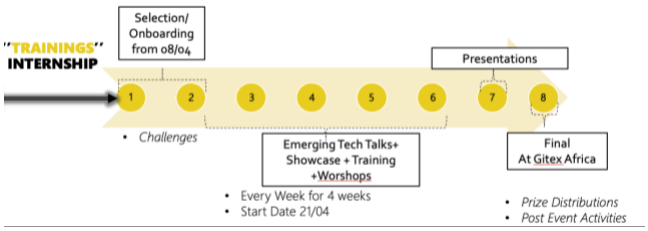

Figure 4: The phases of the training curriculum across 5 weeks.

The training curriculum included weekly seminars open to public, training workshop for participants, showcases and mentoring sessions (see Figure 4). The discussions forming the bae concepts of the participant projects were held in the light of IRCAI's research and research achievements (see Figure 5), aiming at building research collaboration bridges.

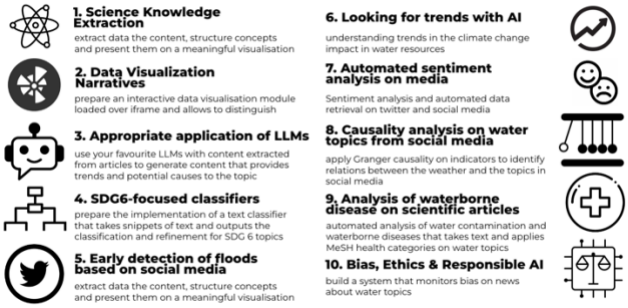

Figure 5: Selected topics from IRCAI's research to motivate challengers in AI and Water research

The data and methods generated by the participants programme can be used by companies, government and research institutions to aid in the resolution of problems related to Water Sustainability, by identifying trends and major areas of discussion, and to explore successful scenarios through similar challenges and cases. IRCAI's SDG 6 Observatory [10] is being built to properly address the challenges of decision makers, using AI. It is benefitting: (i) national governments providing access to a variety of perspectives (including trend and comparative) on a data driven dashboard with information on Water Sustainability trends for decision-making; access to local (e.g. country-level) progress on SDG 6; (ii) educational institutions, offering access to information on current trends on Water Sustainability research and development; (iii) research institutions, sourcing open data over interactive visualisation and research; (iv) the NGO community, easing access to information directly linked to community priorities including citizen science activities; and (v) general population, empowering water education for all.

4 Conclusions and further work

The capacity building to enhance opportunities can benefit from the engagement of the Youth in AI-driven challenges that start in research problems deriving from issues to address in their communities. Problems they know well and data that they often have privilege access to, with promising impact that can ensure the sustainability of the innovation offered. The initiative served us also to collaboratively discuss sustainable solutions that help large scale recovery and define a better and more hopeful inclusive Africa. The winning outcomes of this challenge will integrate a vibrant worldwide Community of researchers and entrepreneurs focusing on AI and SDGs, starting with SDG 6, and supported by initiatives such as IRCAI's Top 100 or the SDG Observatory. Ethical considerations are being addressed in the context of the EC project AI4GOV.

Abstract

Poverty reduction is the first Sustainable Development Goal set by the United Nations to be achieved by 2030, but current data indicates that the progress is insufficient. The diverse factors influencing poverty across different nations pose a challenge in developing effective predictive models. This paper evaluates the use of various regression models to predict poverty rates using a comprehensive dataset of 111 variables from sources such as the UN and the World Bank. The data, spanning multiple domains like political stability, education, and economic conditions, was preprocessed and transformed to create auxiliary features and interactions. Among the models, Ridge regression yielded the best results, achieving a Root Mean Square Error (RMSE) of 3.6, indicating high predictive accuracy on a global scale. This study highlights the importance of addressing multicollinearity and incorporating a wide range of features to improve the generalizability of poverty prediction models. Future research should explore more complex methods, such as neural networks, and refine model hyperparameters for enhanced performance.

Keywords

poverty, linear regression, lasso regression, ridge regression, elastic net regression, sustainable development goals

1 Introduction

The need to eradicate poverty has been a long standing issue, which was globally recognized numerous times, most importantly in the United Nations (UN) Sustainable Development Goals (SDGs), being given the number one spot of SDG1: "End poverty in all its forms everywhere", which should be achieved by 2030. The latest UN report on the progress made in achieving SDG1 indicates Poverty has returned to pre-pandemic levels in middle- and high-income countries, with poverty in low income countries still a fraction above those reported in 2019. While the trends seem to be going in the right direction, the UN warns that the current pace of improvement is insufficient to reach the agreed goals before 2030. This raises the question of what impacts poverty rates the most and how countries can most effectively reduce poverty levels.

To fully understand and address the issue of poverty, one must navigate several definitions, which can often lead to confusion. The baseline definition used in this paper is the poverty line as is defined by each country individually, recognizing that different countries have different measures of, e.g., what life conditions and how much income makes an individual reach a "poor" status, as well as how we can normalise this to better compare these relative indicators between countries. We are still missing a clear theory in poverty research, despite the issue existing for a number of decades [2]. With that being said, some authors have already explored the causes of poverty. For instance, corruption, political instability, ineffective local governance, government polices, gender inequality and short-term wage replacement policies, such as maternity leave benefits and sickness pay, impact relative poverty [6, 7]. When assessing what people believe causes poverty some geographical differences emerge. For example, the United States are mostly of the thought that an individuals traits are responsible for poverty, while countries in Europe have a blend of individualistic, fatalistic and structural beliefs such as lack of will, bad luck and social injustice respectively [4].

Machine learning (ML) has also been used in academic research to identify trends and analyze data in most fields, including poverty research. Although a number of papers have already been published on the use of ML to predict poverty [1, 10, 12, 5, 3, 8] (for more see [11]) including combining satellite images and neural networks to help predict poverty in five African countries [5], most take a limited number of variables. Usmanova's literature review found 22 papers published between 2016 and March 2022, with a total of 57 AI methods applied, the most popular being random forest, used in more than half of all papers reviewed. It also found most papers focus only on African and South Asian countries, a finding consistent with our own [11].

In this paper we focus on the following research questions: (i) can regression be useful to identify the most influential features, from a large amount of global indicators; and (ii) can direct and indirect causality relations be identified that signal new indicators relevant to the Poverty-related issues?

2 Data

To address the research questions, we utilized 111 primary variables from sources such as the UN and the World Bank, aggregated through the Our World in Data portal. These variables span diverse domains, including political stability, policies, education, healthcare, economic conditions, and inequality. We prioritized features that prior research has identified as significant, while also incorporating some factors that are less intuitively linked to poverty. The dataset was then used to train various models aimed at predicting poverty rates across countries. This task is particularly challenging because countries respond differently to the same variables. For instance, GDP growth tends to have a more significant impact on poverty reduction in developing nations compared to developed ones. Additionally, many variables

https://doi.org/https://doi.org/10.70314/is.2024.sikdd.20

are strongly correlated, making it difficult for linear regression models to capture their relationships accurately.

As previously mentioned, most of the data used in this paper was sourced from *ourworldindata.com* (OWiD), with some additional data coming from *fao.org*—including variables such as foreign direct investment inflows and outflows, and the added value of agriculture, among others. Data on the transatlantic slave trade and colonial rule was obtained from *www.slavevoyages.org*. All datasets were preprocessed before being merged, following a series of steps.

The first preprocessing step involved light modifications, such as removing irrelevant columns, renaming columns, and excluding data from before 1987 and after 2023 due to gaps and incomplete data. Despite increased reporting in recent years, many countries still omit certain indicators, complicating model training. To address this, missing features with more than n data points for a given country were interpolated, with the edges filled using backward fill (bfill) and forward fill (ffill). Those with less than n data points used the mean of the country's income group for the given year as a filler value. The number n was intuitively chosen to be five and the methods bfill and ffill were chosen to prevent the use of unrealistic data. The World Bank classifies countries into income groups: low (less than 1,045 USD), lower-middle (1,046 USD to 4,095 USD), upper-middle (4,096 USD to 12,695 USD), and high income (12,696 USD or more). However, it is important to note that the data generated using the aforementioned methods somewhat reduces overall robustness.

The next step involved generating auxiliary columns, specifically lagged columns and changes in value for relevant parameters. For instance, the row corresponding to Niger in 2013 would also include the GDP per capita for 2012, 2011, and earlier years, in addition to the value for 2013. This approach reflects the fact that poverty trends often manifest in response to changes over time, rather than immediately. The default number of years for lagged data was set to five. Similarly, we incorporated changes in value over the same five-year period to capture more explicit data on unusual events, such as the onset of wars or significant political changes.

Next each primary parameter was also used as an argument for a number of mathematical functions in an effort to see if any correlations aren't linear but perhaps squared, cubed or another elementary function. The functions used were: x^2, x^3, $\ln x$, $\sin x$, $\cos x$, $\tan x$, $\arcsin x$, $\arccos x$, $\arctan x$ to try and capture any elementary nonlinear dependence within the model.

The last step was to create all possible products with the available primary parameters, as creating all possible products with all auxiliary parameters included would have been computationally inefficient. After all these steps were made, the individual columns were fused together. This method of preprocessing increases the possible variables included, making the model even more general and retaining as many rows of data as possible.

The function responsible for preprocessing, generating and merging the data has a few parameters: *basic_parameters_only*, *combinations* and *math*. *basic_parameters_only* determines, if the model will only contain data obtained from various online databases, or if the model should include generated data: the change in value and values for previous years. *combinations* determines, if the model should create all possible combinations with the primary parameters and *math* determines if mathematical columns are included in an attempt to gain a deeper insight into the features' relationships. The parameters are marked with B, C and M. For instance, B+M would mean the file contains the basic parameters in addition to the mathematically derived columns.

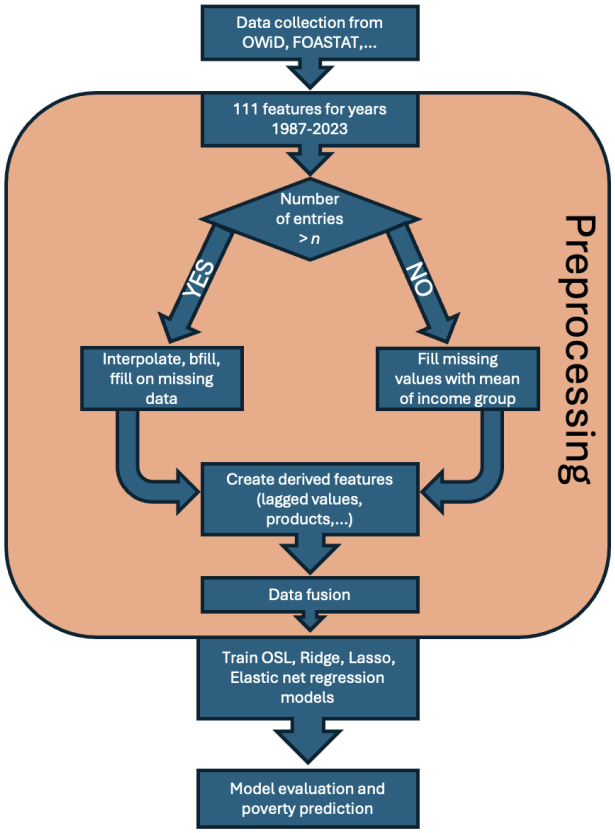

Figure 1: Scheme of adopted methodology

3 Methodology

In order to predict worldwide poverty levels, we have used different linear regression models and compared their accuracies. With this we aimed to ease the interpretability of the models, which is harder to obtain with more complex methods such a neural networks. To perform the research work that is the base of this paper, we have selected ordinary linear regression, lasso regression, ridge regression and elastic net regression as the models to compare. OLS regression struggles with multicollinearity, where predictor variables are highly correlated, leading to unstable estimates of the coefficients. Ridge regression addresses this by adding an L2 regularization term, which penalizes large coefficients and helps to stabilize the estimates in the presence of multicollinearity. By shrinking the coefficients, ridge regression reduces the sensitivity of the model to colinear predictors, ensuring more reliable and generalizable results. Unlike lasso, ridge retains all predictors, making it particularly useful when multicollinearity is a key concern but feature selection is not the goal. We use the implementation of these linear regression algorithms in scikit-learn [9].

The datasets were split into training and test sets using the sklearn function `train_test_split`, with 80% for training and 20% for testing. The training set was used to train four regression variants (`LinearRegression, Lasso, Ridge, ElasticNet`), all with a random state seed of 42. while the test set was used to

determine the mean squared error (MSE) and R^2 value using the functions `mean_squared_error` and `r2_score` from [9], both common metrics used to assess models accuracy. All models except OLS regression also had the data standardized before training. The hyperparameter α for the models was sensibly chosen as 0,1. The results, seen in Table 1 are color coded: red for poor performance, yellow for intermediate, and green for the best. The variation in the number of rows is due to the exclusion of rows with insufficient yearly data, which were dropped when calculating differences from previous years.

After identifying the most successful model, we proceeded to compare its performance between high-income and low-income countries. This comparison aimed to assess how the accuracy and frequency of reported data influence the model's performance. These two income groups were chosen because low-income countries typically report less data with lower accuracy, while high-income countries provide more precise reports. We selected all high- and low-income countries from the dataset that were not used during the model's training. From the 20% of data reserved for evaluation, 444 rows (30%) belonged to high-income countries, and 368 rows (24%) belonged to low-income countries.

We used the trained model to predict poverty levels for these groups and evaluated its performance using the MSE metric to analyze differences between income groups. Additionally, we calculated the maximum error to determine if the average performance was skewed by outliers. A similar evaluation was conducted on the data from Slovenia and Somalia, which were part of the split. Slovenia had 8 rows of data, and Somalia had 6, allowing us to explore how missing data impacts the model's performance, as Somalia had significantly fewer data points overall.

4 Main Results

The file configuration plays a critical role in the model's performance. The results show that C+M, C, and B+C are the best configurations. The C+M file includes all basic features, lagged values, changes in value, mathematical columns, and all possible combinations of basic parameters, totaling 8,236 parameters. Configuration C contains all basic features, combinations, and lagged and difference columns. Lastly, B+C includes only the basic parameters and their combinations. All top-performing models were trained on these datasets.

The results in Table 1 show considerable variation. Models trained with ordinary least squares regression performed poorly, with the best model reaching an RMSE just under 10.15 and an R^2 of 0.50. In contrast, lasso and elastic net regression achieved better results, with RMSEs around 7 and R^2 values close to 0.80. Ridge regression also struggled, except for configuration B+C, which provided the best results with an RMSE of 3.6 and an R^2 of 0.94. However, caution is advised when interpreting models using configuration C+M or C, due to the high number of features relative to the dataset size, which could affect their real-world reliability.

The model weights reveal that only products are present among the top ten most important factors. These products include data on population, population density, agriculture, equality, healthcare, and education. The largest weights show the biggest differences, gradually decreasing in magnitude. The top ten weights range from just over 10 to 7, with the highest weights involving combinations such as population and population density, meadows and pastures with the global peace index, and

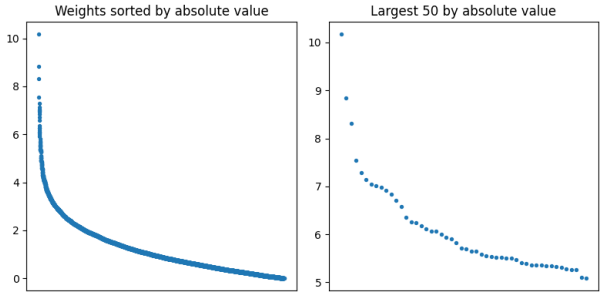

Figure 2: Visual representation of model weights

population with urban and rural population share. Other notable combinations include secondary school completion with women's civil liberties, internet usage with sanitation access, and military spending with wealth distribution. The weights also reflect factors like infant mortality, years colonized, and agricultural employment. Figure 2 further illustrates the decline in the absolute value of these weights.

The model performed better on high-income countries, with an MSE of 6.60, significantly below the overall MSE. In contrast, the MSE for low-income countries was 20.68. The maximum error was also lower for high-income countries (22.1) compared to low-income ones (34.4).

The difference in the model's performance on Slovenia and Somalia was notable. For Slovenia, the MSE was 0.78 with a maximum error of 1.54, far below the overall metrics. Somalia, however, had a much higher MSE of 95.7 and a maximum error of 18.7, likely due to less reliable and extreme poverty data, which skews the model's performance on extreme cases.

5 Discussion

Firstly, the fact that ordinary least squares linear regression couldn't produce an accurate model confirms the fact that the parameters are indeed correlated. This is probably also the reason why the ridge regression model performed the best: ridge regression is used to address the issue of multicollinearity and the features included are mostly strongly correlated, as stated in the introduction. Furthermore, the correlation between parameters is obviously drastically increased by generating all possible products of basic parameters.

Secondly, the impact of mathematical columns needs to be considered. Of the first four models, two have mathematical columns and two don't. Of the eight models generated, three of them perform worse if mathematical data is present, while 5 performed better with mathematical data included. This might indicate some deeper connection, which would be interesting to try and understand. Furthermore, lasso regression handles mathematical columns much better compared to the other models used due to its ability to exclude features.

The impact of product combinations of basic features stands out, with all better-performing models having the *combinations* parameter set to `True`, suggesting deeper relationships between variables. Exploring these connections further, perhaps by training a neural network on the basic parameters and comparing it to linear regression models, could be insightful. If the neural network performs better, further investigation into these correlations would be needed.

Structure	Linear MSE	Linear R^2	Lasso MSE	Lasso R^2	Ridge MSE	Ridge R^2	Elastic net MSE	Elastic net R^2	Shape of X
M	203	0.031	74	0.65	-	-	-	-	(7653, 2131)
None	-	-	109	0.48	163	0.22	108	0.49	(7653, 1221)
C+M	198	0.054	45	0.78	-	-	40	0.81	(7653, 8236)
C	-	-	50	0.76	-	-	45	0.79	(7653, 7326)
B	103	0.50	110	0.47	103	0.50	111	0.46	(7661, 111)
B+C	-	-	48	0.77	13.3	0.94	43	0.79	(7661, 6216)

Table 1: MSE and R-squared values for different regression models and dataset configurations. The presence of B, C or M signals the presence of basic basic parameters only (B), combinations (C) and mathematically (M) derived columns in the dataset. A dash is used to label non-converging models with a negative R-squared value.

The dataset used spans from 1987 to 2023, which is relatively short, given that poverty often has deep historical roots. Although data becomes scarcer in earlier years, those points could still be crucial for improving model accuracy. Moreover, most hyper parameters in this paper were chosen sensibly due to time and computational constraints. Different values for the number of lagged years, years of differences, hyperparameters in the training of models and the minimum number of data points required to interpolate missing data could all lead to interesting discoveries and improvements of the generated models. Our result here shows it is possible to achieve this degree of accuracy, but it doesn't limit what the best model could be. The elastic net, especially, should benefit from such a tuning.

As stated in [11], the recent literature mostly uses the random forest model and, in fact, ordinary linear regression wasn't even in the top ten most common methods. An interesting thing to explore would also be the performance of random forest using the best configuration, B+C. The models may struggle to capture correlations between variables due to differing impacts across countries, as mentioned in the introduction. A potential solution is to split the countries into k groups and train separate models for each group. While this could improve predictions, it raises two challenges: how to split countries without bias and how to ensure enough data for training.

The weights in the model further emphasize the issue of multicollinearity among the parameters, with only product terms emerging as the most influential. However, this does not reveal the true importance of individual parameters, as they may enhance the impact of another factor within the product term. Additional research is needed to better determine the true significance of these parameters and gain a clearer understanding of what drives poverty rates up or down. It can be seen in Figure 2, the models weights occupy a wide range. It is clear that some features are more important, based on their weights and further work is being done to understand which features stand out and why.

The model also performed better in predicting poverty levels in high-income countries compared to low-income countries. This discrepancy can likely be attributed to the fact that high-income countries report more data with greater accuracy, allowing the model to identify underlying patterns more effectively. In contrast, much of the data for low-income countries had to be interpolated, which reduced variability between countries and negatively impacted the model's performance.

6 Conclusion

In this paper, we have shown that a general model exists, based on linear regression methodologies, which can predict poverty with a relatively high accuracy (RMSE of 3.6). This was achieved through testing of numerous linear regression models using open data, with the best model being created by using ridge linear regression trained on data which also included all possible combinations of the basic features included in the dataset. The basic parameters included consist of 111 different parameters describing countries across 36 years. Better models could possibly be generated using more complex methods such as neural nets or random forest, gaining in accuracy but compromising the explainability of the model. The models could also benefit from hyperparameter tuning during the whole process to improve results and find the optimal values. We will be addressing this in further research.

Abstract

Advancements in artificial intelligence and increased internet accessibility have made it simpler to create and disseminate fake news with customized content. However, they also improved the ability to analyze and identify such misinformation. To effectively train high-performance models, we require high-quality, up-to-date training datasets. This article delves into the potential for generating fake news through factual modifications of articles. This is facilitated by prompt-based content generated by large language models (LLMs), which can identify and manipulate facts. We intend to outline our methodology, highlighting both the capabilities and limitations of this approach. Additionally, this effort has resulted in new quality synthetic data that can be incorporated into the standard FAK-ES dataset.

Keywords

fake news, synthetic data, fact extraction, fact verification, large language models

1 Introduction

Synthetic data refers to artificially generated data that is not obtained by direct measurement or observation of real-world events. Instead, it is created using algorithms and simulations. The primary purpose of synthetic data is to provide a realistic alternative to real data for various use cases, such as training machine learning models, testing systems, ensuring data privacy, and more.

We will generate synthetic data from news articles. By making sure, that the information in the news is changed we can safely call it fake news. In our article, fake news will denote articles that are *intentionally* and *verifiably* false [4]. Synthetic data enhances model training by providing additional examples to supplement scarce labeled datasets and allows for privacy-conscious testing without real content manipulation. It enables adaptability to evolving fake news tactics by simulating diverse scenarios from the newest data, thereby improving the robustness and resilience of detection algorithms [3].

Large language models (LLMs) made a huge difference in the world of news. Fake news is now much easier and cheaper to construct, but we also have additional methods to help us tackle its spread. Numerous articles appeared trying to partake in this effort. The following are the main scientific contributions of this paper:

(1) A methodology to create synthetic data for fake news using LLMs.
(2) We then use this methodology, to adapt the FA-KES dataset with 100 additional synthetic fake news [1].

In Section 2, we discuss work that is closely related to our task. Section 3 then outlines the methodology for generating synthetic fake news, culminating in Section 4, where we present the results and introduce some modifications to the methodology. Finally, in Chapter 5, challenges, capabilities, and potential improvements are considered.

2 Related Work

A wide range of approaches to generate fake synthetic news with LLM has been developed. In [8] authors generated huge amounts of fake news and categorized them into multiple categories. LLMs can generate fake news by altering the style to mimic credible sources or using sensationalism to influence perception. They can subtly manipulate content to be perceived as true, blend real and fabricated information to exploit cognitive biases, or create convincing fictional narratives.

In general, when making a dataset we want a diverse distribution of fake datasets. In our case, we will focus on one way of data change, which comes under the umbrella of *Content Manipulation*. Similar news manipulations can be seen in [7] where the authors use two main techniques. The first one extracts the summary from the original text, which preserves the main content, which is then changed to produce a fake article. The second one asks a question about the article and changes the content of its answer, to construct a new article. Our approach is in nature similar to the Question-Answer framework.

Many articles provide fake news detection models made using synthetic data. Most popular are deep neural networks such as BERT [1]. But there are other fact-based approaches for fake news labeling as in [3]. In [2] they used GPT4-turbo for prompt-driven fake news detection.

3 Methodology

The methodology is divided into four conceptual steps: Data collection, Characterization of facts, Fact extraction, and Fact manipulation as presented in Table 1.

3.1 Data Collection

The publicly available FA-KES dataset [5], focused on the Syrian war, addresses the deficiency of manually labeled datasets in this domain of news data. It comprises 804 articles sourced from various media outlets. We used 426 articles that were manually labeled as authentic news, but we could just as well use the other (fake) articles.

1. Data collection	2. Characterization of facts
• Should have textual and statistical facts	1.Name of casualty 2.Gender or age group 3.Cause of death 4.Type 5.Actor 6.Place of death 7.Date of death
3. Fact Extraction	**4. Fact manipulation**
Name of casualty: Civilians **Gender or age group**: e.g., child, adult, senior **Cause of death:** shooting, shelling, weapons, etc. **Type:** military personnel **Actor:** rebels, forces **Place of death:** Airbase **Date of death:** April 7, 2017	**Name of casualty**: Manipulated fact **Gender or age group**: Manipulated fact **Cause of death:** Manipulated fact **Type:** Manipulated fact **Actor:** Manipulated fact **Place of death:** Manipulated fact **Date of death:** Manipulated fact

Figure 1: A methodology to generate synthetic data for fake news detection

3.2 Characterization of Facts

While making the FA-KES dataset, its authors created seven factual categories:

(1) `Name of casualty or group`,
(2) `Gender or age group`,
(3) `Cause of death`,
(4) `Type`,
(5) `Actor`,
(6) `Place of death`,
(7) `Date of death`.

It is crucial to note that all articles have a similar structure, describing war incidents. This allows us to establish a consistent framework of facts, such as actor and casualty details. We stick to those facts, but generate them differently, employing LLMs capabilities with faster and cheaper execution, albeit with a slight reduction in reliability.

3.3 Fact Extraction

We extract facts by constructing prompts for LLMs. First approach was a few-shot prompt, which gives some examples of output. Later we constructed an additional approach: Say we are extracting the fact `Place of death` with this second technique. We give a detailed description of what should be extracted and then LLM reads the article and performs the task solely on this basis. This description is usually longer and contains more context. The issues with fact extraction in general are:

- Some articles lack certain facts or merely imply them. LLMs can identify this, outputting responses such as "No information."
- Longer articles may contain multiple events, each with distinct data such as dates or casualties. This can be managed by creating separate tables for each event or consolidating all events into a single table with various facts.

3.4 Fact Manipulation and Synthetic News Generation

The objective is to modify relevant information without altering the writing style or topic of the article. For this transformation, we used a chain of thought prompt, which for a given fact: 1) changes the fact to another with a different meaning, 2) generates a new article based on the altered facts. By changing one fact at a time, quality is improved compared to altering multiple facts simultaneously, as one fact creates a clearer chain of instructions. LLMs such as `Llama3.1:8B` often struggle with precise changes in the article, such as modifying implicit references or incorporating new facts. Quality can be improved by carefully adjusting the prompt content.

LLMs are also exceptional in summarization and paraphrasing. Both are used simultaneously with changing the facts. The problem is that we aim to maintain the extracted facts when summarizing. But this is not crucial, as it usually has better results as article generation.

3.5 Fake News Annotation and Fact verification

After we have generated the fake articles, we can label that data as "fake" or "non-fake", based on comparison with extracted facts. We performed this labeling with various models and compared the performance of labeling,to get the best model. In this experiment we decided for `Llama3.1`. To do the labeling, we are performing fact verification [4]. The fact verification task in general is making a decision as to whether a claim is correct, based on the explicitly-available evidence, such as Wikipedia articles or research papers. We have the extracted fact, which will be compared to the article content. The question thus becomes: Do these facts appear in the given article? This approach emphasizes factual content rather than the overall sentiment of the article.

There are two primary types of prompts: 1) Direct prompts that present the article and a table of facts, asking if the facts relate to the article, 2) Structured prompts that inquire about the correspondence of one fact at a time with the article. The question is: Does this fact correspond to the content of the article? This method combines individual results into an aggregated score. Say the `Place of death` is characterized as `Idlib and Daraa provinces`. Then the question posed to LLM is of the form: `Read the article and understand its places of death. Do Idlib and Daraa provinces "really correspond" to places of death in the article?`

We are not as interested in labeling, as we are interested in the quality of produced synthetic fake news. For this purpose, we will also use fact verification in a slightly different way. We are asking the LLM: Were the factual changes in fake news really made, as they were supposed to? A similar method is used in the article [7].

4 Experimentation and Results

4.1 Experimental settings

We selected 426 articles labeled as authentic news from FA-KES dataset. Then facts were extracted and transformed, as described in the previous section. At first two basic approaches were used to randomly choose 70 news articles and transform them. Afterward, we used the labeling procedure to compare performance, resulting in the table 1. Based on the results we then composed the final algorithm, which would be manually evaluated.

4.2 Evaluation

For every experiment, we first manually checked a minimum 10 percent of random examples to get an overview of how well the LLM was able to do the job. It is quite useful to print text that represents the procedure of decision-making that LLM undertakes, when challenged with the task. It was even helpful to see LLMs generated thinking procedure, as this gives valuable insight, into what is going on "under the hood". We believe that manual fact-checking is the first and most crucial step in generating good prompts. Based on fallacies one can then adjust prompts content. To shed some light on this procedure we have made the following overview.

4.3 Fact Extraction Results

Name of casualty or group:	Members of Nusra Front
Gender or age group:	Adults (no specific age mentioned)
Cause of death:	Explosion at a mosque
Type:	Non-civilian (militants)
Actor:	Unknown (no group claimed responsibility, but supporters blamed ISIS)
Place of death:	Ariha, Idlib province, Syria
Date of death:	Not specified in the article

Figure 2: Example of fact extraction.

LLMs are capable of recognizing different topics and extracting words that correspond to this topic, and also noting if the fact is not mentioned. At first, we extracted short words as represented in Figure 2.

The issue begins with nuances. For example, in many articles the `Actor` is only suspected but not known. In some cases, actor and causality are not precisely distinguished. This usually leaves LLM to some kind of arbitrariness. For this purpose, We also added a longer description that better captures the nuanced subtleties related to facts. This can also be captured in Table 1. There we see the results for short (normal) or detailed extracted facts. The recall is far worse in the case of short prompts. This likely means that there is an abundance of false negatives, which result from the fact, that labeling does not manage to match true articles and their corresponding short facts.

The shorter extracted facts are often not comprehensive. For example, under the label `Type` (which classifies civilian or non-civilian) it writes only civilians, even though, contextual understanding also includes some non-civilian casualties.

Overall the most important insight remains: fact extraction has better quality than article generation.

4.4 Quality and coherence of synthetically generated fake news

The LLM can detect (for example) the `Actor` of some attack in the news, and then it is mostly able to change every occurrence of this `Actor` with another `Actor`. But if we would like to preserve all the coherence of the article much more would need to be done.

News usually contains background information, that provides context for the accident. Our algorithms failed to properly adjust this context, leaving it unchanged in most cases. Our fake news fails to preserve enough coherence to be trusted by a skeptical reader, who tries to connect background material to the event in the article.

Table 1: Comparison of fake synthetic data.

Type of data	Number of facts manipulated	Precision	Recall	F1	Accuracy
Summarization	2/7	0.74	0.63	0.68	0.71
Detailed facts	2/7	0.70	0.80	0.75	0.73

Generating false text, while maintaining coherency, is challenging for LLM. In this task, we have changed one fact: for example, the `Place of death` may be changed to another city or neighborhood. Then this fact must be changed in the article while maintaining other factual information. Here are the main issues:

- In the beginning some facts did not get changed, or the facts were altogether just removed from the article. We managed to reduce this error by adjusting the prompt. It is difficult to adjust all occurrences of the fact, especially if it is only implied and not explicitly stated. We managed to minimize this problem, by a method yet to be shown in section 4.5.
- What remains is the problem of a wider context, Suppose we change the town of the incident, then we must change the name of the neighborhood accordingly. LLM usually fails in this, leaving our article inconsistent, which is a widespread problem.
- LLM does not want to output the content because of harmful content or does not want to produce articles that could be used with illegal intent. This was quite a common problem, which is also reasonable, based on the violent content of articles and the possible abuse of LLM-generated content. The best thing to prevent this error is to use uncensored LLM. In other cases, one can adjust the prompts by removing suspicious words like "fake news".
- The Generated article was shorter, skipping the original text which was not linked to extracted facts. This problem was reduced but still exists in long articles.
- If the fact is not present in the article, then it is hard for LLM to incorporate a new fictitious fact into the text. Mainly it just adds the information in separate sentences.
- When we change facts, traces of the old facts still persist. This is especially common in complicated articles with diverse structures.
- Sometimes the change does not bring about any additional meaning. For example, LLM might change previously unknown casualties and designate them as civilians. They were implied to be civilians all along, and this makes only a minor change and is not really fake.

4.5 Fact verification with LLMs

Remember that in this task, the prompt asks: Does this fact "really correspond" to the content of the article? Performance largely depends on how the program takes the word "really correspond". Words have many nuances: different words can have different meanings, which can complicate labeling. To simplify: we can be stricter, in the sense that words must be the same in the literal sense, or we can count on the similarity of meaning [6]. Based on our goal of creating fake news it is best to focus on meaning and not concrete words.

Here are some common problems:

- Sometimes the fact is changed, but LLM skeptically assumes, that those two names refer to the same group.
- In longer articles, where there are many events, the names get changed only in some events (usually at the beginning of the article). In this case, the LLM can make unwanted predictions, labeling the fact as true rather than false.

Manual checking shows that labeling is more accurate than generation of fake news. This leads us to use labeling as a means to improve article generation.

Table 1 was used to compare different ways to generate fake news. It shows two of the best datasets, which contain true articles and their false twins, generated in two ways:

(1) Fake news generated by "standard" fact extraction and with additional summarization.
(2) Fake news generated by "detailed" fact extraction and with an additional paraphrasing of the article.

In this experiment, instead of merely categorizing the articles as true or false, the results shown in Table 1 reflect how well the generation process aligns with fact verification.

Low precision in the row with Detailed facts led us to detect articles that were not changed. We implemented a strategy where labeling was applied after generating the fake articles to assess the quality of the generation. LLMs often provide incomplete responses and struggle to correct them directly. By introducing an additional verification step, we were able to enhance the overall accuracy of the results.

4.6 Final Dataset Description

In the end, we constructed 100 fake-news based on a prior experiment, which can be found on GitHub [2]. In every article we randomly chose three facts and changed them. Afterward, we carefully went through 10 examples, which are also present on Git Hub, while here we present only the main points:

- Fact verification improved quality by making sure, that the synthetic fake article really incorporated new information. More than 90% new facts really got incorporated in the article. Sometimes new information is only added as additional text(and does not seriously change the main topic).
- Fact is not always incorporated in all places where it is referenced, which leads to inconsistencies. The new article is then a blend of old and new information.
- There are problems with ¨detailed" prompts. Containing more information results in contradictions as we change only one fact at a time.

5 Conclusion

In this article, we focused on exploring the potential of LLMs in fact extraction and generation of fake news. Our motivation was primarily to understand how accurate are LLMs in fact extraction and how reliably LLMs generate synthetic news by altering facts. As a result of our experiment, we have generated 100 synthetic news by randomly transforming there out of seven facts and have performed a manual evaluation, to observe the quality of the generated news dataset.

5.1 Problems, Capabilities and Possible Improvements

- In this stage, LLMs like *Lamma3.1:8B* are not able to coherently change certain facts of news articles. Changing facts can distort the article content, which appears to be extremely hard to manage. This normally does not happen for manageable data as dates (changing the time of some event), but for much more involved actors of the attack in the article. Even so, the synthetic fake news provides valuable information.
- We did not use the model, which has additional information about the news content. Providing additional context would likely have a beneficial effect on all the processes.
- In our case facts were largely dependent on each other. For example `Gender or age group` is an extraction of `Name of casualty or group`. We think it is best if such dependencies are removed because they bring to inconsistencies when changing facts. An additional solution would also be to change `Gander or age group` whenever `Name of casualty or group` is changed.
- Fact extraction is close to human-like quality. The issue is, that besides manual checking, it is hard to find a good measure of the quality of extracted facts.
- Detection of changed facts is in quality similar to extraction of facts (this is not surprising, since they are based on the same skill). Because of the diversity of meanings in language, it is hard to specify the exact reasoning procedure of LLMs and many mistakes come from this kind of miscommunication.

Borrowing Words: Transfer Learning for Reported Speech Detection in Slovenian News Texts

Zoran Fijavž
Jožef Stefan Postgraduate International School
Peace Institute
Slovenia, Ljubljana
zoran.fijavz@mirovni-institut.si

Abstract

This paper describes the development of a reported speech classifier for Slovenian news texts using transfer learning. Due to a lack of Slovenian training data, multilingual models were trained on English and German reported speech datasets, reaching an F-score of 66.8 on a small manually annotated Slovenian news dataset and a manual error analysis was performed. While the developed model captures many aspects of reported speech, further refinement and annotated data would be needed to reliably predict less frequent instances, such as indirect speech and nominalizations.

Keywords

reported speech, natural language processing, transfer learning, news analysis

1 Introduction

Reported speech, ubiquitous in literary and news texts, has clear lexical and syntactic patterns which may be reliably modeled via natural language processing (NLP) and may be useful for downstream tasks by drawing a distinction between source and background information. The paper applies transfer learning to extend reported speech classification to Slovenian news texts and provides a provisional classification model. A manual error analysis reveals the model's strengths and weaknesses, highlighting possible steps for further improvements.

2 Related Work

2.1 Role of Reported Speech

Reported speech is common in news texts, generally expressed as direct or indirect speech, with the former repeating the original utterance verbatim and the latter embedding it in a that-clause [18] (e.g., *Jimmy said: "Another systematic review would be great!"* and *Jimmy said that another systematic review would be great.*). More complex forms include mixed speech (*City officials rebuffed the accusations as "groundless and blatantly false".*) and reportative nominalizations with an analogous function as reported speech (*The speaker particularly emphasized the pressures on the media*) [7]. Around 50% of sentences in newspaper corpora may be attributed to a source in the text, predominantly through direct and indirect speech [17]. Verbs cue 96% of reported speech, followed by prepositional phrases (3%) [13]. Reported speech lends objectivity to statements [9], summarizes source statements [16], and is used in discourse analysis and communication studies to explore speaker representation by gender [1], institutional affiliations [8], and topic stances [15], or to distinguish between journalists' and sources' voices [11].

2.2 Existing Datasets and Modelling Approaches

Datasets with reported speech annotations mostly cotain literary or news texts. Key corpora include RiQuA [12], SLäNDa 2.0 [19], Redewiedergabe [3], QUAC [14], PolNeAR [10], Quotebank [21], and STOP [22]. RiQuA and Redewiedergabe are the largest annotated corpora, covering English and German 19th century texts. QUAC contains 212 annotated articles from the Portuguese newspaper Público, while Quotebank spans 162 million news articles with automatic annotations. PolNeAR, consisting of 1,028 news articles, includes attribution annotations, which include and exceed the definition of reported speech. A summary of the datasets is provided in Table 1.

The corpora differ in annotation complexity and size. They are mostly monolingual, warranting the used cross-lingual transfer learning for low-resource languages by employing multilingual models such as mBERT [6] and XLM-R [4]. Narrower multilingual models, such as CroSloEngual BERT, often outperform broader ones [20]. Reported speech modeling may be operationalized as speaker or quotation detection tasks [23, 17]. Simplifying the task to sentence-level classification is warranted by the fact news (unlike literary texts) rarely mix statements by sources and authors in the same sentence and can improve classification reliability at the expense of detailed aspects of reported speech [17] and simplify the annotation structure. Missing fine-grained outputs, such as speakers and boundaries of reported and reporting clauses, may thus be an acceptable trade-off for NLP-based content analysis in news texts. A systematic review of such approaches points to the limits resulting from a low number of features with no guarantee of reliable (joint) prediction, which preclude drawing rich conclusions expected from the method's manual counterpart [2].

3 Experimental Setting

3.1 Task Overview

We treated reported speech as a sentence-level classification task. Sentence splitters were applied to existing datasets, and binary labels were assigned by matching annotated spans with the split sentences. Reported speech sub-types were unified under a single label, joining the annotation schemes of individual datasets. A Slovenian dataset of 10 news texts was manually annotated at the sentence level. The datasets were split into training, evaluation, and test sets to train multilingual pretrained models. For CroSloEngual BERT, preprocessing also involved machine translating the German training data into English. The model outputs were binary labels indicating reported speech, used to calculate F-scores on the test data. A manual error analysis was performed on

Table 1: Summary of Datasets' Characteristics.

Corpus	Type	Annotations	Language	Sentence No.	Role	Positive Class
RiQua	fiction	direct and indirect speech, cues, speakers, addressees	English	38,610	72% train, 18% development, 10% test	48%
Redewiedergabe	fiction, news	direct, indirect, free indirect and reported speech, speaker, cues	German	24,033	76% train, 16% development, 9% test	33%
Quotebank (manual)	news	speaker, direct speech	English	9,071	test	30%
QUAC	news	speaker, direct speech	Portuguese	11,007	test	11%
PolNeAR	news	speaker, cues, attributions	English	34,153	test	59%
Slovenian parliamentary news	news	sentence-level binary labels	Slovenian	744	test	43%

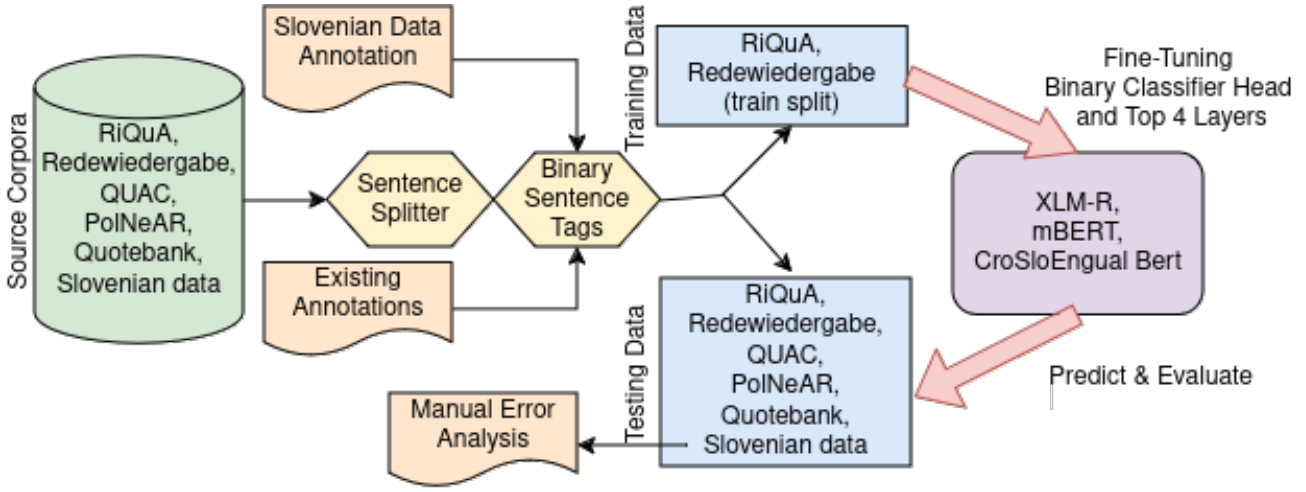

Figure 1: Flowchart of Data Preprocessing, Model Training and Evaluation Processes for Sentence-Level Reported Speech Classification.

the best model's outputs for Slovenian. Preprocessing, training, and evaluation steps are visualized in 1.

3.2 Training and Test Data

Our experiments were based on existing annotated reported speech datasets and a small Slovenian dataset. The training data included sections from RiQuA and Redewiedergabe, both large datasets with labels for direct and indirect speech. For CroSloEngual BERT training, the Redewiedergabe data was machine translated into English. Testing was conducted on the test sections of RiQuA, Redewiedergabe, the entire Portuguese corpus QUAC, and the manually annotated portion of the English Quotebank corpus. Additionally, we manually annotated 10 Slovenian news articles from RTV Slovenia. The datasets are summarized in Table 1.

The Slovenian dataset comprised 10 parliamentary news texts, covering various reporting strategies. Retrieved articles were split into sentences and annotated. Sentences were considered reported speech if they included direct or indirect speech cued by a reporting clause or prepositional phrase. We excluded nominalizations and phrasal quotes (e.g., *They emphasized the pressures on the media and the "illegal non-funding of the Press Agency."*) as well as implied quotes (e.g., *There will be more than 300,000 recipients, he emphasized. 169 million euros will have to be paid out.*).

3.3 Evaluation Procedure

The models' performance on the test datasets was calculated with an F-score. A baseline of assigning a positive label to all examples was calculated for all test datasets. The models' results on the test datasets were compared with a Friedman's test as suggested in the literature [5].

The best Slovenian model's predictions were reviewed with close reading. The error typology consisted of direct speech, indirect speech, speech fragments, annotation errors, annotation errors and *unrelated* and *other* tags. *Direct speech fragments* were sentences part of multi-sentence direct speech quotations. *Annotation errors* were examples with annotations inconsistent with the definition described in *Section 3.2.* For *unrelated* examples, close reading revealed no clear misclassification cause. *Other* was used for examples that did not fit any of the mentioned categories.

3.4 Training Settings

XLM-R and mBERT were used as base models with the default training settings from the *transformers* library with the exception of using 16 gradient accumulation steps and freezing the bottom 8 layers of all models. The latter reduces the training time without significant performance drops (Kovaleva idr., 2019; Merchant idr., 2020). Additionally, a Slovenian-Croatian-English BERT model was trained on English machine-translated data from Redewiedergabe.

4 Results

4.1 Model Results

The model performance varies based on the congruence between the language and precise task definitions in each dataset. The differences between model predictions were not statistically significant (χ^2_F = 9.66; df = 5; n = 8; p = 0.14) so post-hoc tests were not performed. As Table 2 demonstrates, the XLM-R model trained on both RiQuA and Redewiedergabe performed well across the datasets with an F-score of 80.5 and 77.6 on the Redewiedergabe and RiQuA test set, respectively. The high results from training on combined data suggests the RiQuA and Redewiedergabe datasets may benefit from additional or complementary data, at least when using cross-lingual transfer learning. The most successful strategy for Slovenian data was training on RiQuA and English machine-translated Redewiedergabe data using the CroSloEngual BERT model, reaching a F-score of 66.8. We did not evaluate the impact of using translated training data with mBERT and XLM-R.

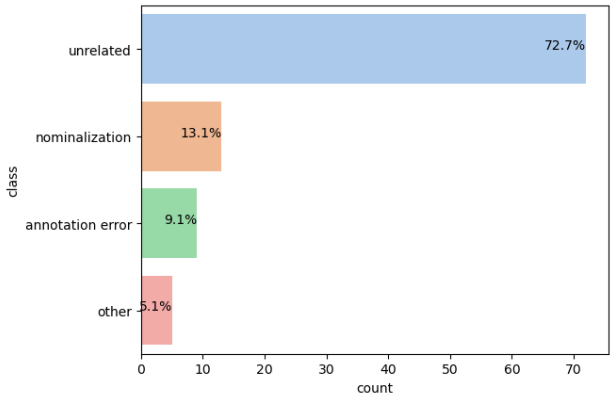

Figure 2: False Positives from the CroSloEngual BERT Classifier.

4.2 Error Analysis Results

The results from CroSloEngual BERT on Slovenian data were analyzed further. False positives were more common than false negatives, representing 23.4% and 9.8% of all examples (n = 744), respectively. Close reading of a sample of 100 false positives did not show a definite pattern for most (72.9%) of them. These examples were clearly unrelated to reported speech, although some did include words lexically related to reporting verbs (e.g. *The proposed law is still under discussion*). The second category of false positives were nominalizations of reported statements (13.1%) not included in our annotation schema. The final source of false positives were annotation errors consisting of wrongly

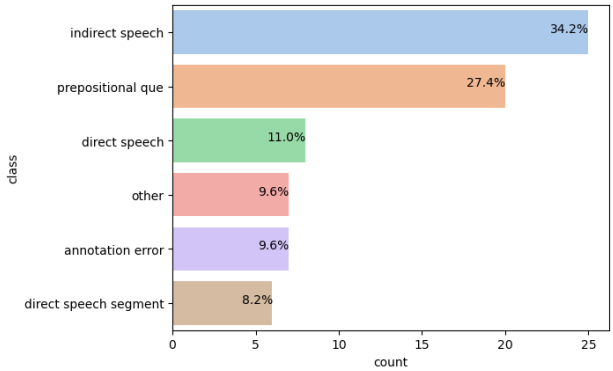

Figure 3: False Negatives from the CroSloEngual BERT Classifier.

unmarked examples of direct or indirect speech (9.1%). The distribution of categories identified in the sample of false positives are illustrated in Figure 2. The most common errors in the 73 false negative examples were instances of indirect speech (34.2% of false negatives) and prepositional queing of reported speech (27.4%). The remainder were instances of direct speech, direct speech fragments and annotation errors representing 11%, 8.2% and 9.6% of the false negatives, respectively. The annotation errors included nominalizations and statements reported as adjective complements (*The speaker was happy that the provisions were accepted)* not included in our annotation schema. Figure 3 summarizes the identified false negative categories .

5 Discussion

This paper presents the development of a reported speech classifier, tested through a small annotated Slovenian dataset and manual error analysis. Cross-lingual transfer learning from the annotated RiQuA and Redewiedergabe datasets achieved an F-score of 66.8 on a small manually annotated dataset of Slovenian news of parliamentary sessions using the base CroSloEngual model with RiQuA and English machine-translated Redewiedergabe training data [1]. This these results corroborate the observation that language models trained on a limited number of languages may outperform less specialized ones such as mBERT and XLM-R [20]. The major source of errors were false positives (23.4% of all sentences) for which no systematic pattern was discernible in the majority (72.9%) of examples. Instances of indirect speech and prepositional queing of statements were overrepresented in the false negatives, accounting for 61.6% of false negatives. Although rare, nominalizations were present in both false positives and false negatives and should be considered in future annotation guidelines. These obeservations indicate reported speech classifiers may benefit form approaches for addressing imbalanced classes.

6 Conclusion

This study developed a sentence-level reported speech classifier for Slovenian news texts using cross-lingual transfer learning. By leveraging existing multilingual models (mBERT, XLM-R, and CroSloEngual BERT) with the English and German datasets RiQuA and Redewiedergabe, we demonstrated that sentence-level

[1]The fine-tuned CSE model is available on the Hugging Face Hub under the name *zo-fi/rep-sp-CSE-rwg-riq*.

Table 2: Model Performances across Datasets (F-scores).

	Redewiedergabe	RiQuA	PolNeAR	QUAC	Quotebank	Slovenian dataset
Positive by default	52.1	60.6	74.2	19.5	45.8	60.3
mBERT+Both	77.5	77.4	73.1	40.5	53.5	63.2

CroSloEngBERT+Both+MT	54	76.6	73	24	52.5	66.8

classification can detect some aspects of reported speech in Slovenian. However, the performance estimates are limited due to the small size of the Slovenian testing set and the limited definition used for the annotations. Future research should focus on developing a Slovenian annotated dataset, refining the annotation schema for multiple use cases, and exploring additional modeling features such as encoding broader sentence contexts. This work contributes a provisional tool for computational discourse analysis of Slovenian media texts. Further development is necessary for its application in more nuanced tasks.

ABSTRACT

In this paper, we examine the relationship between the discussion of Environmental, Social and Governance (ESG) in companies' annual financial reports and their financial performance. Specifically, we analyse the companies' use of specific ESG terms alongside the performance metric, sector-normalized Return on Assets (ROA). Our motivation is to determine whether companies frequently mentioning terms such as "gender", "equality", "talent", and "innovation" in their reports demonstrate a higher annual ROA compared to those that rarely used these terms. To explore this, we used existing datasets with reports and performance metrics from 348 companies, covering the years from 2009 to 2021. In order to better examine differences, we then selected companies whose ROA significantly differed from the average (either higher or lower), allowing for a more pronounced examination of the impact of ESG term usage on financial performance. The filtered dataset consisted of 107 companies, with a total of 427 reports; split into two sections representing higher and lower performing companies. We then used an existing list of ESG terms derived from a range of separate data sources, and applied a basic statistical n-gram language model to extract the probabilities of each ESG term's occurrence in each of the higher- and lower-performing dataset sections. Results show that while certain sets of ESG concepts correlate with higher financial performance, others do the opposite, and give some initial interpretation into the light this sheds on company reporting behaviour.

KEYWORDS

financial report analysis, language modelling, environmental, social and governance reporting

1 INTRODUCTION & RELATED WORK

There is increasing interest in the behaviour of companies in the area of Environmental, Social and Governance (ESG) criteria, including a company's environmental impact (Environmental), relationships with the community including employees, suppliers and customers (Social), and leadership structures including executive pay and shareholder rights (Governance). Although until recently, ESG analyses were almost entirely performed manually by experts (see e.g. [10]), there has been a large amount of work in the last few years on applying computational machine learning and statistical methods to ESG analysis (see e.g. the recent review by Lim [9]).

However, much of this analysis examines numerical company performance data and categorical metadata; our interest is in developing and applying natural language processing (NLP) technologies to not only help automate analyses, but allow understanding of how human actors discuss and understand the important and meaning of ESG aspects.

Application of NLP in finance is not new: for example, topic modelling has been used to predict company performance and investigate strategies [14, 7]. Recent work also includes application to ESG aspects: Nugent et al. [12] automatically extract news about ESG controversies, and Lee et al. [8] analyse sentiment on ESG issues. Closer to our interests, Purver et al. [13] investigated how the use of ESG terms by companies has changed over time. By analysing and annotating a set of existing resources, they defined a set of 93 ESG terms categorised into 5 core ESG areas. They then showed how these terms can be used to analyse changes in reporting, by analysing a collection of company annual reports, collated over a period of 8 years, using language modelling and distributional methods to reveal changes in the frequency and in the usage of the ESG terms.

Here, we are interested not in changes in ESG discussion over time, but in whether and how the reporting of ESG aspects is connected to financial performance. We take Purver et al. [13]'s resources and methods as a starting point, but augment the financial report text data with available metadata on financial performance, allowing us to compare how ESG reporting varies between more and less well-performing companies.

2 DATA AND METHODS

2.1 Hypotheses

In general, we expect increased probability of appearance of ESG terms in the annual reports from the more profitable firms, based on a number of factors. In general, overall high ESG performing companies exhibit high financial performance [1, 5]; although we note that the link between high ESG score performance and mention of ESG terms is not guaranteed to be straightforward. More specifically, during the period between 2010-2020 analysed here, there was a growing emphasis on corporate social responsibility (CSR) and sustainability. Investors, consumers, and other stakeholders increasingly prioritised companies that demonstrated a commitment to innovation, diversity, and environmental sustainability [11, 2]. Busru and Shanmugasundaram [3] find that firms closely engaging in fostering innovation, attracting top talent,

Year	# Reports	# Words
2012	178	12.5M
2013	181	14.0M
2014	184	15.0M
2015	196	16.3M
2016	198	17.5M
2017	200	18.4M
2018	200	19.6M
2019	202	21.2M
total	1539	134.6M

Table 1: Number of annual reports available by year

promoting gender and diversity initiatives, could confer a competitive advantage over the industry peers. Furthermore, some policy and regulatory changes (e.g. the 2018 UK Corporate Governance Code, the 2014 EU Directive on Non-Financial Reporting, Carbon Disclosure Project (CDP)) directly or indirectly encouraged companies to address issues related to diversity, gender equality, and environmental sustainability.

2.2 Data and pre-processing

To test this hypothesis, we build on the resources and methods of Purver et al. [13], who provide a dataset of annual reports from FTSE350 companies over the years 2012-2019, based on the FTSE350 list as of 25th April 2020 and obtained from the publicly accessible collection at www.annualreports.com. The reports are already converted to plain text, and we use their publicly available tools to tokenize the collection into words and build ngrams of length 1-4 padded with sentence start and end symbols; the dataset size is reported in Table 1 below (taken from [13]). We use their set of ESG terms, defined via a process of extracting candidate terms from a set of public ESG definitions and taxonomies, asking financial expert annotators to label them as to their representativeness as ESG terms and their ESG subcategory, and keeping the terms with high inter-annotator agreement (see [13] for details).

2.3 Financial performance analysis

The reports were then linked to financial indicators for the respective year and company. The data on company fundamentals was obtained from the Refinitiv EIKON Datastream.[1] Each entry contained annual financial indicators, as well as the companies' industry and sector codes. The main variable of interest was normalized, averaged *return on assets (ROA)* as defined below:[2]

$$\frac{\begin{array}{l}NetIncome - BottomLine \\ +((InterestExpenseOnDebt - InterestCapitalized) \\ \times(1 - TaxRate))\end{array}}{AverageOfLastYear'sAndCurrentYear'sTotalAssets}$$

After extracting financial reports with available ROA data, we categorized the financial reports into two groups, in order to examine differences in the associated reports' use of ESG terms. The distribution of ROA shows a heavy concentration around the mean, so in order to derive two distinctive groups we took the two extremes and excluded the central group around the mean. The 'negative' group comprised reports with a yearly ROA less than -0.2, indicating very poor performance. Conversely, the 'positive' group included reports with an ROA of at least 0.2, reflecting very good yearly performance.

Subsequently, we employed a statistical n-gram language model (using NLTK[3]) to analyze the occurrence of each ESG term. For each term, we calculated the probability of its occurrence in positive reports (p_+) and in negative reports (p_-), and the difference ($p_+ - p_-$). Terms with a large difference in these probabilities are more strongly associated with positive reports than with negative ones, and vice versa: terms with a large negative difference are common in negative reports but rare in positive ones. We conducted this analysis for both unigrams and bigrams.

3 RESULTS AND DISCUSSION

The results for 1- and 2-grams are shown in Figures 1 and 2 below (3- and 4-grams showed no clear interpretable associations).[4] As hypothesized, many ESG terms show a strong association with positive performance, with many of these being core terms associated with human resources (*innovation*, *talent*), with social aspects (*gender*, *diversity*), environmental aspects (*renewable*, *carbon footprint*, *environmental impact*) and overall ESG descriptors (*ethical*). However, many terms are conversely (and contrary to our general hypothesis) associated with negative performance, including, again, terms across various ESG categories including environmental (*carbon emissions*, *energy efficiency*, *greehouse*), human resources (*mental health*, *wellbeing*) and general ESG descriptors (*governance*).

However, by combining these terms with recent work in clustering and describing ESG terms [4], we can shed more light on which categories seem to be more positive and which more negative. Ferjancic et al. [4], using the same dataset and ESG term list [13], perform a further topic analysis using BERTopic [6], in which they derive 30 ESG-related topics and 6 higher-level clusters of ESG concepts; they then examine the correlations between these ESG topics and company ESG scores as obtained from external analysts. We align our ESG terms with Ferjancic et al. [4]'s 30 topics by matching against the words most associated with each topic (if a term appears in the top 10 words associated with a topic, we take the term and topic as aligned); we can then compare our positive/negative associations with Ferjancic et al. [4]'s correlations with company ESG scores. Table 2 shows this alignment for our most positive and negative bigram terms here, with the topic labels and an indication of the strength and direction of correlation with overall company ESG scores, as given by [4].

Given this, we see some systematic groupings. *Climate change*, as part of the 'climate risk and policy' topic, as well as *supply chain* and *human trafficking* as part of the 'human rights' topic, represent the themes that appear to be, across different industries, related to high company ESG scores. A similar observation holds for *gender balance*, *gender pay* and *environmental impact*, which all fall in a group of topics which are strongly and significantly correlated with high ESG scores throughout different industries. Overall high ESG performing companies exhibit high financial performance [1, 5], therefore our results for terms such as *climate change*, *supply chain* and *human trafficking* are not surprising: as indicators of topics associated with high ESG, they are good terms for tracking these ESG aspects associated with high financial performance.

[1] https://www.refinitiv.com
[2] We use this normalization and averaging to smooth and remove one-off effects.
[3] https://www.nltk.org/
[4] Note that these figures show differences in absolute probabilities: magnitudes are comparable within 1-grams, and within 2-grams, but not between 1- and 2-grams.

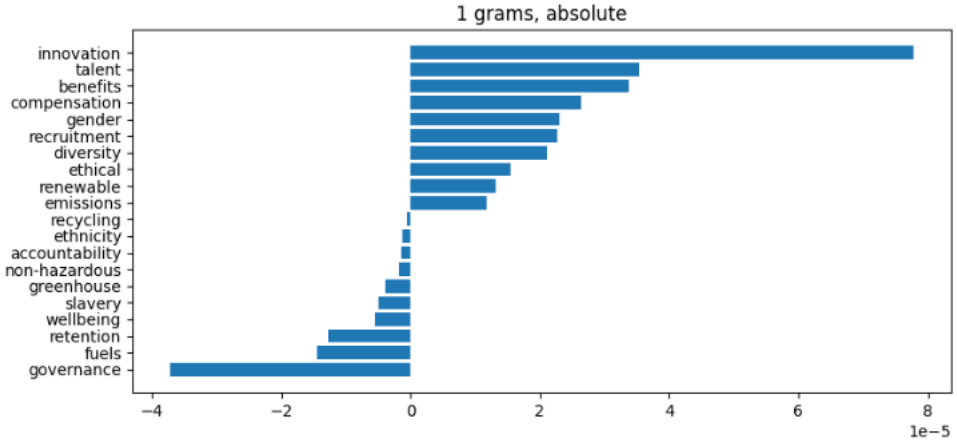

Figure 1: Difference in probability between positive and negative reports $p_+ - p_-$ for the most positive and negative unigram ESG terms.

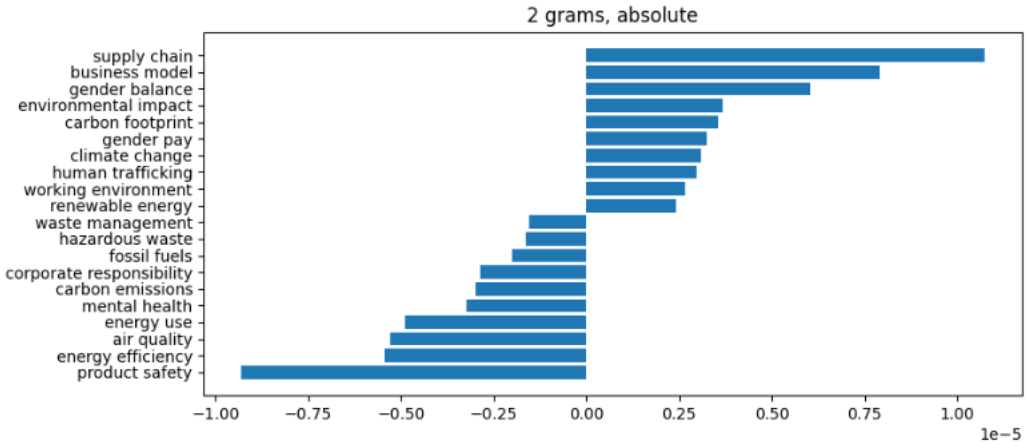

Figure 2: Difference in probability between positive and negative reports $p_+ - p_-$ for the most positive and negative bigram ESG terms.

Looking at the terms with low values which are associated with low RoA, *waste management* and *corporate responsibility* are associated with topics, for which in some industries proportion of these correlate with ESG scores significantly positively and in other industries this correlation is significantly negative. Based on overall correlation between ESG scores and topic proportions across different industries, these two topics are among the third of the topics for which negative correlation between the topic proportion and ESG score prevails. Due to the aforementioned correlation between ESG and financial performance it is therefore understandable that these terms are associated with mention in annual reports of companies with low RoA. Overly extensive discussion on specific topics (such as 'waste management' and 'corporate responsibility') can negatively impact ESG score (see [4]) which can by analogy of ESG and financial performance [1, 5] hold for companies with low RoA.

There is a surprising number of bigrams in both the high RoA and low RoA groups which seem to be associated with the same topic, namely 'climate footprint and energy management'. For companies with high RoA, these terms are *carbon footprint* and *renewable energy*, and for companies with low RoA, the terms are *fossil fuels*, *carbon emissions*, *energy use*, *air quality* and *energy efficiency*. It seems that better performing companies use *carbon footprint* instead of *carbon emissions*, and discuss more on the use of *renewable energy* than on *energy use*, *energy efficiency* and/or *fossil fuels*. In future work, we plan to analyse the use of these terms in more depth, including analysis of the lexical and topical contexts in which they appear, and adding techniques such as sentiment and topic analysis to shed more light on these distinctions.

Abstract

Various platforms, including patent systems and repositories like GitHub and arXiv, support knowledge dissemination across domains. As knowledge increasingly spans multiple disciplines, there is a need to track innovations that intersect various fields. Despite available data, a comprehensive knowledge taxonomy for effectively tracking innovations across domains is lacking. Developing such a taxonomy and employing automated classification methods will enhance the ability to track shared knowledge.

In this work, we first developed a knowledge taxonomy based on the CPC schema. We formulated the classification of textual data into defined knowledge fields as a multi-label problem. Then, we evaluated the effectiveness of the classification models by fine-tuning pre-trained transformer language models. The multi-label framework enables the tracking of knowledge trends at the intersection of various disciplines.

Keywords

Knowledge Taxonomy, Knowledge Tracking, Patent Classification, Hierarchical Classification, Multi-label Classification

1 Introduction

According to the World Intellectual Property Organisation (WIPO), a patent is an exclusive right granted for an invention, providing legal protection to the inventor while simultaneously benefiting society by making the invention publicly accessible [1]. Each year, patent offices receive numerous patent applications that need to be processed [13].To ensure the novelty of patent applications, inventors should also be able to search existing patents. Organising patents with unique codes in a hierarchical structure aids efficient retrieval and aligns with natural human navigation, starting from broad categories and narrowing down to specifics[21]. Among these hierarchical structures, the CPC system is widely recognised [6]. The CPC codes are organised as a taxonomy, meaning that each entity in the lower level is the detail group of the parent. A patent can be assigned to one or more labels by the experts in patent offices [8, 18]. In the first level of the CPC hierarchy, there are nine sections, which are divided into classes, subclasses, groups, and subgroups. Each level of this hierarchy can have several codes ending in approximately 250,000 classification labels [11]. An example of the hierarchical structure of CPC code is provided in Tab. 1.

The CPC schema's top level has only nine sections, but the number of groups increases substantially at lower levels. In this study, we created a knowledge field taxonomy by merging CPC's detailed classes into a more abstract representation. This taxonomy not only serves as a framework for knowledge representation but also offers a benchmark for patent classification systems. While some studies address the issue of numerous class labels by excluding less-represented classes or truncating hierarchies [24], a consistent benchmark taxonomy has been lacking. Since our proposed knowledge taxonomy aligns with the CPC schema, it is able to provide a benchmark for future studies, facilitating the comparison of different models.

In summary, our paper's contribution is the proposal of a knowledge field taxonomy, KnowMap, which aligns with the widely used CPC schema. The KnowMap merged several class labels within the CPC schema based on the scope of the knowledge field and the number of patents associated with each class. The KnowMap taxonomy is available online [2]. In this study, we also performed a classification task to categorise patents into the fine-grained classes defined by our proposed taxonomy.

Table 1: Example of a sequence of codes across different levels of the CPC hierarchy

CPC	Code	Title
Section	H	Electricity
Class	H03	Electronic circuitry
Subclass	H03C	Modulation
Group	H03C3/00	Angle modulation
Subgroup	H03C3/005	Circuits for asymmetric modulation

2 Related Work

Patent documents contain various types of information, including text, diagrams, plots, and references to other patents or scientific publications [20]. The textual content of a patent is divided into several sections, such as the title, abstract, claim, and description [11]. The title and abstract are shorter than the description but still provide relevant information for classification. Li et al. [15] evaluated various lengths of the abstract and title, finding that using the first 100 words of title and abstract resulted in the best classification performance in their study.

Various classification systems exist for organising patents [6]. In this work, we focus on the CPC schema. The hierarchical representations help organise patents and facilitate efficient searching. Kamateri et al. [11] discussed several potential challenges that artificial intelligence technologies face in patent classification. One such challenge is the extensive number of class labels. As an example, the IPC contains approximately 86,000 classes, while the CPC has around 250,000.

Patent classification is a multi-label classification problem since every patent can belong to several knowledge fields [18,

10]. Given the large number of classes at the lowest level of the taxonomy tree, the performance of automatic models in predicting such granular categories is limited. Various models have been used to classify patents in a multi-label setting, ranging from classical machine learning models to deep learning models [15, 5, 8]. Several previous studies have focused on higher levels of the hierarchy, limiting classification to broader categories such as sections, classes, or subclasses within the taxonomy [3]. Bekamiri et al. [3] fine-tuned the SBERT model to predict labels at the subclass level (i.e., 663 class labels) using a multi-label formulation. They achieved F1-score of 66%, outperforming previous studies that used the same datasets. Aroyehun et al. [1] similarly truncated the IPC hierarchy at the subclass level and predicted these labels by transferring knowledge from two higher levels (section and class) to the lower level (subclass), achieving a precision score of 0.53. While it remains valuable for patent office experts to use an automatic model that can narrow down applications to higher levels of the taxonomy tree, this approach has limitations and challenges. One such challenge is that the choice of target class labels does not depend on the scope of the knowledge area. More established and expansive areas may benefit from directing experts to detailed groups, while less developed areas may be adequately served by broader classifications.

3 Methods and Materials

In this work, we developed a knowledge taxonomy and classified patents into fine-grained classes by fine-tuning pre-trained models. Below, we outline the methods and materials used.

3.1 Patent Collection and Preprocessing

The dataset used in our experiments is the Google Patents Public Datasets on BigQuery [3]. Each patent has several pieces of information, including the publication number, application number, CPC code, title, abstract, and detailed description. We have expanded the dataset to include the titles associated with each CPC code from Espacenet. [4]. In this study, we focused on the textual data. We generated the input text by concatenating the title, followed by the abstract, and then the description. We included only those documents where the concatenated text is at least 100 words long. Previous studies have examined various lengths of textual data and found that using the first 100 words often results in higher performance for classification tasks [15].

To create a hierarchical structure where we have enough documents among leaf-node labels (i.e., avoiding scenarios where one group contains only a few hundred documents while others contain hundreds of thousands as an example), we needed to count the number of documents which fall into the defined categories. As a preprocessing step before counting, we performed de-duplication, which involved removing duplicate and near-duplicate textual data [4, 12, 14].

Due to the large size of the dataset, we employed MinhHash Locality Sensitive Hashing (LSH) as a deduplication method to efficiently identify similar documents [7, 9, 22]. Specifically, we used MinHash to approximate the Jaccard similarities between sets of n-grams within the documents. MinHash is particularly advantageous for large datasets because it supports parallel computation, enhancing scalability [2]. We set the similarity threshold at 0.9, meaning that documents with a Jaccard similarity of 90% or higher were considered duplicates. To generate the hash signatures in MinHash, we used 128 permutations. For the n-gram representation, we used a range of 1 to 3, incorporating 1-grams, 2-grams, and 3-grams.

3.2 Refining Hierarchical Structure Through Group Merging

The hierarchical structure of the CPC groups was refined at each level of the tree. We started with nine sections at the top level (i.e., *level 1*), which were preserved. At subsequent levels (i.e., *level 2* to *level 4*), groups were merged by manual analysis based on shared knowledge and the number of documents. Groups with relatively few documents (i.e., groups with fewer than 40,000 for *level 2*, 20,000 for *level 3*, and 9,000 for *level 4*) were combined with other groups at the same level that shared similar knowledge. As an example, at the subclass level of the CPC hierarchy, "A01B" (i.e., Soil working) and "A01C" (i.e., Planting, Sowing, Fertilising) represent related steps in agricultural practices, as both are foundational processes in land preparation and management. We merged them into a single group labelled "Soil working and planting," resulting in 162,567 patents in this category. The refinement continued until the fine-grained classes contained at least 9,000 documents.

3.3 Text Classification

We formulated the classification problem as a multi-label problem, in which each document can be assigned to multiple knowledge fields. In this study, we aimed to classify the patents into the fine-grained classes in the lowest level of the proposed taxonomy (i.e., 83 classes). To balance performance and computational cost given the large size of the dataset, We used the pre-trained language models *distilroberta-base*, a distilled version of RoBERTa [16, 19], and *all-MiniLM-L6-v2*, a version of MiniLM fine-tuned for semantic similarity [22, 17]. The pre-trained models were fine-tuned for the downstream task by adding a classification head. The classification head takes the hidden state of the first token from the model and processes it through a fully connected dense linear layer, followed by a dropout layer for regularisation and a tanh activation function for non-linearity. Since our task is multi-label classification, the output logits for each class are converted into probabilities using a sigmoid function.

For model training, we used a learning rate of 4e-5 with a linear scheduler and a weight decay of 0.1. To prevent overfitting, the best checkpoint was selected based on evaluation metrics on the validation set. We trained the model for up to 5 epochs with early stopping criteria based on validation accuracy. The dataset, consisting of 1,092,991 samples randomly selected after deduplication, was split into training, validation, and test sets with ratios of 0.8, 0.1, and 0.1, respectively. To preserve the ratio of samples per class in training, validation, and test sets, we used stratified splitting [5].

3.4 Classification Evaluation

The F1-score is a common metric for classification tasks. We report both Micro-F1, averaged across all instances, and Macro-F1, averaged across all classes.

4 Results and Analysis

In this section, the results are presented in two parts. First, we present our proposed KnowMap taxonomy. Then, we report the

[3]https://github.com/google/patents-public-data
[4]https://worldwide.espacenet.com/
[5]https://github.com/trent-b/iterative-stratification?tab=readme-ov-file#multilabelstratifiedkfold

performance of classifiers in categorising patents into the fine-grained classes of this taxonomy.

4.1 The Proposed Knowledge Mapping Taxonomy (KnowMap)

The taxonomy, along with the associated CPC sections, classes, subclasses, groups, and subgroups are provided in the shared online source. An example of detailing the knowledge field of *soil working and planting* within the broader knowledge field of *human necessities* is illustrated in Fig. 1.

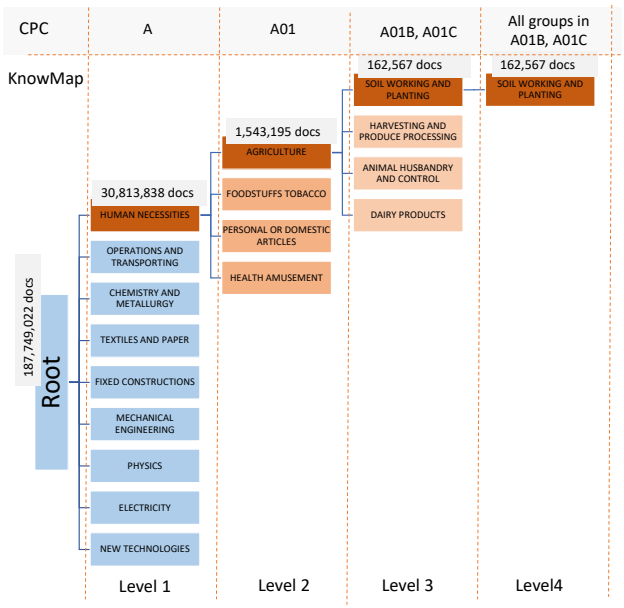

Figure 1: An example of a branch extension in KnowMap from the root to the lowest level, showing the association of KnowMap classes with corresponding CPC classes at each level.

4.2 Classification Results

The classification task in this study was to classify patents into 83 fine-grained classes within our proposed KnowMap taxonomy. The dataset comprised 1,092,991 documents, which were split into the train, validation, and test sets with a ratio of 0.8, 0.1, and 0.1 respectively. We preserved the ratio of samples per class in all three sets with stratified splitting. The average number of documents in the train set, validation set, and test sets are presented in Tab. 2.

Table 2: Overview of sample metrics: total number of samples, average number of samples per class, and normalised average number of samples per class across training, validation, and test sets.

Set	Total	Avg/ class	Normalised Avg
Train	1,092,991	132,202	0.012
Val	874,372	16,476	0.012
Test	218,619	15,543	0.012

Table 3: Classification Results

Metric	RoBERTa	SBERT
Micro-F1 (Val)	0.76	0.76
Macro-F1 (Val)	0.86	0.86
Micro-F1 (Test)	0.77	0.76
Macro-F1 (Test)	0.90	0.90

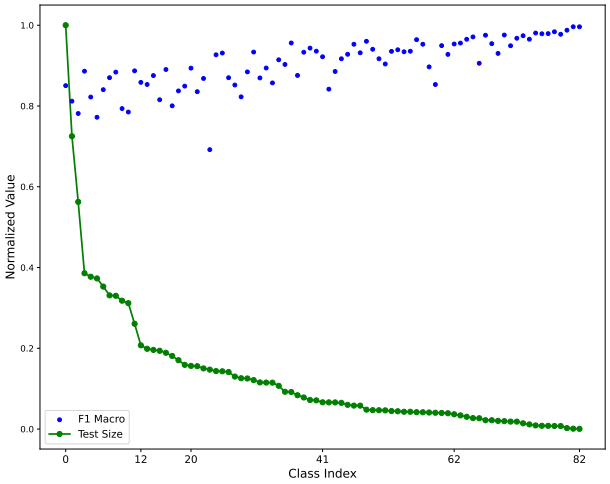

Figure 2: Normalised test size along with F1 Macro scores for each class. The x-axis represents class indices. The y-axis shows normalised values for test size and F1 Macro scores (blue dots).

We demonstrated the experimental results on the two classification models *RoBERTa* and *SBERT* in Tab. 3.

As observed from the results, the Macro-F1 score is higher than the Micro-F1 score, which may indicate that the model performs better for minority classes compared to majority classes. To gain more insights into these results, we generated a plot (see Fig.2), showing the F1 scores along with the normalised number of documents for each class in the test set. We used normalised values to allow both F1 scores and class sizes to be displayed in a single figure, facilitating better comparison.

The plot shows that the Macro-F1 score is higher for minority classes than for majority classes, also indicating that random sampling led to an unbalanced dataset. The imbalanced sample likely caused the higher Macro-F1 score relative to Micro-F1, reflecting poorer performance in the majority classes. Future work will focus on using balancing techniques when sampling to address this issue and enhance model performance.

When looking more closely at the lowest F1-Macro scores, we found that the bottom 10 classes were all leaves under the *chemistry and metallurgy* section. Moreover, the highest F1-Macro scores (0.996) were achieved by the two classes in the *textiles and paper* section, followed by all 17 leaves from the *physics* section. We suspect this performance difference may be due to greater variation in the textual data of *chemistry and metallurgy* class compared to *physics* and *textiles and paper*, leading to more variation between the training and test sets. Analysing this variation in detail remains a task for future work. Additionally, we believe future work could benefit from adapting the classifier to a hierarchical structure, prioritising correct predictions at higher

levels before refining predictions at the leaf level. In our current approach, the classifier does not account for the hierarchy and predicts all leaves directly.

5 Discussion and Conclusions

In this work, we proposed a knowledge field taxonomy, KnowMap, which aligns with the widely used CPC schema. The taxonomy consists of 83 groups at the lowest level, with fine-grained classes containing a minimum of 9,000 samples from the original Google Patents Public Dataset after preprocessing. KnowMap serves as a benchmark taxonomy, addressing a gap in the existing literature.

From the preprocessed original dataset, we randomly selected 1,093,151 samples to fine-tune pre-trained RoBERTa and SBERT models for downstream tasks. However, the random sampling resulted in an unbalanced dataset, which contributed to higher Macro-F1 scores compared to Micro-F1 scores. To enhance classification results, we plan to create a balanced dataset from the original data. Additionally, we aim to use larger models than those used in this study to further improve the fine-tuning process.

6 Future Work

Several knowledge platforms, such as news sites and GitHub, host various types of information shared online. In future work, we aim to incorporate these sources to extend and enhance the knowledge taxonomy's coverage. For example, the All Science Journal Classification (ASJC), which organises research publications by subject area, can be used to identify alignments with the existing taxonomy. This taxonomy alignment can then be further analysed to determine whether to merge or split classes at various levels. Beyond patents, we plan to evaluate the classifier on other data, using domain adaptation methods to transfer knowledge from the labelled patent domain to those with limited or no labels. Large language models (LLMs) could further aid in evaluating the classifier's performance across different domains. Recent research has shown the potential of LLMs to augment or even replace human-labeled training data with labels generated by these models [23].

Moreover, we plan to enhance the classification task by balancing the dataset using balancing techniques for multi-label problems and leveraging larger pre-trained models. we will also closely examine the different knowledge fields to better understand the variations in classifier performance across them.

ABSTRACT

When building a causal graph from textual sources, such as media reports, a key task is to provide an accurate semantic understanding of the causal variables encoded as nodes and to link them to existing ontologies with at least two purposes: (i) expand the knowledge with the domain knowledge captured in such ontologies and (ii) provide accurate and different levels of abstraction of the extracted causal variables. This article describes how we used OntoGPT, a tool for matching raw text to ontology concepts initially designed for the medical domain, to match concepts from media events to relevant ontologies. We build upon our previous work on extracting causal variables and enrich the extraction pipeline by matching causal variables to concepts from specific domain ontologies. In particular, we describe our work regarding the GEO ontology. Future work will focus on expanding OntoGPT's capabilities by utilizing a wider selection of ontologies. Addressing its limitations, such as dealing with multiple instances of the same class, will also be crucial for improving its utility. These improvements will allow the tool to better support strategic foresight applications by providing more detailed insights across a multitude of different sectors, further enriching causal graphs and facilitating more accurate predictive modeling.

KEYWORDS

strategic foresight, ontology matching, artificial intelligence

1 INTRODUCTION

Strategic foresight is a discipline concerned with anticipating future trends, uncertainties, and disruptions to inform decision-making and enable the creation of resilient, long-term strategies. As such, it is valuable to governments, organizations, and enterprises, who can use it to remain competitive and adaptable in a rapidly changing world [4].

The pace of technological advancement, shifting geopolitical landscapes, environmental crises, and unpredictable market trends make it essential to react quickly to change. Traditionally, foresight has been based on trend analysis, expert opinion, and qualitative insights. Such approaches lack the agility required to scan real-world events in near-real time and produce strategic foresight outcomes at such a pace. Nevertheless, this would be possible with the use of artificial intelligence.

AI enhances strategic foresight by automating the analysis of data and detecting patterns that may go unnoticed by human experts [1]. Machine learning algorithms can continuously monitor emerging trends, geopolitical shifts, and market fluctuations in near-real time, offering dynamic insights into potential future scenarios. Natural language processing (NLP) enables AI to sift through massive amounts of text, extracting relevant information from reports, news, and social media, thus accelerating the forecasting process. By integrating AI into strategic foresight, organizations can adapt more swiftly and make more informed, data-driven decisions in the face of uncertainty.

Ontologies provide structured knowledge informing the relationships between concepts within a specific domain. Furthermore, they describe those concepts through properties and can link such classes to specific instances observed in the real world. As such, they are of key importance when building a causality graph, given they can augment our understanding of the causal relationships between variables with a better understanding of the context and the variable implications [3]. For example, if the causal relationship reports about the ceasing of an armed conflict, knowing whether a causal variable relates to a country, the location of that country, the neighboring countries, and international organizations it is involved in would help to understand the magnitude of that event and contextualize other likely outcomes (refugee repatriation, impacts on investments, and others).

In the scope of the graph massive project, ontology matching is being used to link the extracted causal relationships from text to concepts inside the ontologies, allowing for a more detailed understanding of the concepts that appear in causal relationships and their interconnectivity.

2 ENRICHING CAUSAL GRAPHS WITH DOMAIN KNOWLEDGE

We consider ontologies a framework (an organized and structured system for representing knowledge) used to represent knowledge within a specific domain by defining the relationships between concepts. They consist of classes (concepts), properties (attributes), and relationships that connect different concepts. This structure provides a standardized way to organize and interpret data, ensuring consistent understanding across systems. For example, in a medical ontology, concepts like "disease" might be linked to "symptoms," "treatments," and "causes," each with its own defined properties. By formalizing these relationships, ontologies allow AI systems to better interpret and reason about

complex information, leading to more accurate data processing and decision-making.

Ontologies enhance causality graphs by providing domain-specific knowledge that improves the accuracy and depth of relationships represented. When extracting causal relationships from large datasets, such as media reports, the data can often be ambiguous or incomplete. Ontologies address this by offering structured knowledge that defines concepts and their relationships within a specific domain, linking extracted causal relationships to well-defined entities in the ontology. This enriches the causality graph, uncovering implicit connections and non-obvious relationships that may otherwise be missed. In strategic foresight, for example, ontology-based enrichment helps capture a broader range of potential future scenarios by incorporating knowledge beyond the immediate dataset. This leads to more reliable predictions, especially when the training data is limited or domain-specific. Ultimately, ontologies are expected to enable the system to generalize better, predict outcomes with higher accuracy, and improve the overall reliability of causality graphs.

The causality graph pipeline in the Graph Massivizer strategic foresight project is designed to automate the extraction, organization, and analysis of causal relationships from large datasets, particularly news articles. The Figure 1 showcases the structure of our causality graph's data pipeline. The process begins with extracting these relationships from news articles, which are then organized into a causality graph that maps the interactions between various factors and events. The goal is to develop link prediction models that estimate the likelihood of future events based on observed patterns. For instance, one use case involves predicting oil price trends by analyzing factors that influence pricing.

Ontology matching is then integrated into the pipeline to link extracted causal relationships with concepts from structured ontologies. This enrichment adds layers of context and enables the discovery of connections that may not be evident from raw data alone. By incorporating ontologies, the pipeline transcends the limitations of its training data, identifying causal relationships that may be implied by broader knowledge contained in the ontologies. This not only enhances the accuracy of the graph but also allows it to capture more complex and non-direct relationships, improving its predictive capabilities.

As shown in Fig. 1B, the process of ontology linking in our pipeline consisted of creating ontology matching templates, then linking the concepts in text to ontologies, using the information to add additional data to existing causalities, all with the purpose of finding extra implicit connections based on the information provided by the ontologies.

The main problem that needed solving for that purpose was, how to link ontologies to raw text data. In our case that was done using OntoGPT [2], which is a tool used for ontology linking. Another key challenge is inter-ontology matching, which involves linking multiple ontologies through shared concepts. This process expands the knowledge framework, making it even more valuable for our purposes. The challenge of inter-ontology matching hasn't been addressed yet and remains a matter of future work.

3 ONTOGPT: A BRIEF OVERVIEW

OntoGPT is an advanced tool that integrates large language models (LLMs) with ontologies to improve knowledge extraction and organization across various domains. Ontologies provide a

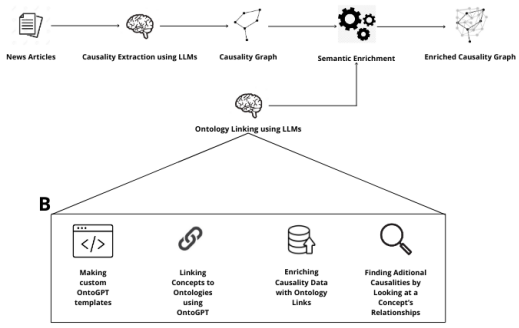

Figure 1: The figure showcases our pipeline for building a causality graph. The sub-figure B showcases how the process of ontology linking was executed as a part of our pipeline

consistent and accurate representation of complex information by defining structured relationships between concepts.

The primary purpose of OntoGPT is to enhance AI systems' understanding, processing, and categorization of data by linking extracted information to predefined concepts and relationships within an ontology. This structured approach ensures greater accuracy and reliability compared to traditional AI systems that rely on unstructured data.

OntoGPT works by connecting data from sources such as text or reports to specific concepts in an ontology, allowing for more informed and contextually accurate connections. For example, in healthcare, OntoGPT can link symptoms from patient records to diseases and treatments outlined in medical ontologies, helping to suggest possible diagnoses or treatment plans.

By combining the language-processing capabilities of LLMs with the structured knowledge available in ontologies, OntoGPT enables AI systems to go beyond keyword matching and consider the relationships between terms. This leads to more intelligent data interpretation and improved decision-making.

OntoGPT is widely used in fields where structured knowledge is critical for high accuracy, such as healthcare, biology, and pharmaceutical research. In medical research, for instance, OntoGPT links clinical trial data, medical records, and scientific literature to medical ontologies, supporting better analysis and decision-making.

The key advantage of OntoGPT lies in its ability to ground AI outputs in domain-specific, structured knowledge, reducing the likelihood of errors and improving the relevance of insights. This grounding ensures that AI responses are not just based on patterns but also on well-defined concepts and their relationships.

In summary, OntoGPT bridges the gap between the raw data-processing power of LLMs and the structured knowledge in ontologies. By leveraging both, it provides a more accurate and reliable approach to extracting and linking data across various domains, particularly when working with large, complex datasets.

3.1 OntoGPT's role

At a lower level, OntoGPT operates using YAML templates that define how data should be extracted from text and linked to ontological concepts. These templates serve as blueprints, specifying which types of entities, relationships, and properties to look for in the input text. The templates guide the large language model by mapping textual data to predefined concepts and relationships

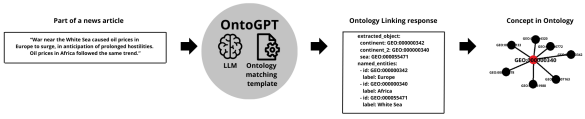

Figure 2: A Showcase of the function of OntoGPT

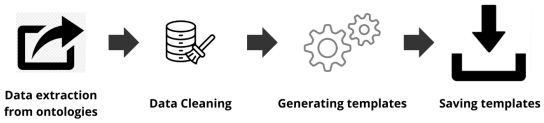

Figure 3: The Process of Templates Generation

from the ontology, ensuring that the extracted information is both relevant and structured. The figure 2 shows the process of ontology linking for an example of a simple sentence. Each YAML template contains detailed instructions on how to identify key terms, their corresponding ontology classes, and the relationships between them. This allows OntoGPT to recognize when a piece of text, such as a sentence from a media article, contains a concept that aligns with an entity or event in the ontology. Once identified, the tool links the extracted data to these ontology entries, enabling richer and more meaningful connections in the data, as it is now grounded in an established knowledge framework.

The approach described in this article uses an ontology file as input to create such templates for data extraction and linking. This enables for a broader range of ontology linking, as the templates can be created on demand.

4 TEMPLATES AND PYTHON CODE GENERATION

The approach works by using the information defined inside the ontology, to generate the YAML templates. The Figure 3 showcases the process of how this is done.

First the class information, for each class inside the ontology, is extracted. This is done by using the "owlready2" python library to parse the ontology into an object, and then extract the relevant information from the new object.

Every class inside the ontology is used to create a corresponding template class, which is optimal, as it covers all parts of the ontology that could potentially be linked. A small portion of the data extraction process is ontology-specific and was custom-tailored to the individual ontology, as some information (like class descriptions) is saved in different parts.

Secondly the data extracted from the ontology is processed and used to create custom YAML templates. This is done by simply using the extracted information to fill in a "general template" we used for generation. Specifically the class names and descriptions are used, to do so. This gives OntoGPT the names of the classes inside the ontology, that we are trying to link the text data to, and their descriptions, which assists OntoGPT in more accurately identifying these classes inside the text. The YAML file also contains the information of "annotators" which tells OntoGPT, which ontology to ground the responses to. The generated YAML templates are saved into a separate file after generation, which makes them ready for use.

The python code that is used by OntoGPT in the process of ontology linking, is similarly generated by using the extracted information to fill in the "general template" and is then saved to a separate file.

5 LIMITATIONS

5.1 Multiple Same-Class Concepts

OntoGPT has problems trying to link two or more concepts to a place in the ontology if the concepts are of the same class. This happens because both concepts suit the description and similar criteria that OntoGPT extracts the information based on. This causes OntoGPT to merge both concepts into a single string and then try to locate the said string inside the ontology, which fails because there is no individual inside the ontology class with such a name. An example of such a response is shown in Listing 1:

Listing 1: Example of a bad response

```
extracted_object:
  continent: AUTO:Europe%2C%20Africa
named_entities:
  - id: AUTO:Europe%2C%20Africa
    label: Europe, Africa
```

If OntoGPT managed to locate the concept inside the text in the ontology, it returns its id (an example of this is "sea: GEO:000055471" and "id: GEO:000055471 : White Sea") If the concept suits the class criteria, but couldn't be located inside the ontology, it returns it as a "AUTO" detection. For the purpose of ontology linking this is not optimal as it does not give us access to the additional information that is stored inside the ontology's individual information. The ontology's individual information is a set of predefined relationships and properties, that an individual concept has. For example, if the individual "Africa" is defined inside the ontology, the individual's data would include its size, countries on the continent, population, and climates, among others. This information gives us reliable information about a certain concept, allowing for more contextual understanding.

To solve this problem, the approach of creating "buffer" classes was taken, where a certain class from ontology would be used to generate three classes describing the different occurrences of the ontology class and a description that would provide sufficient context to OntoGPT to separate the same class concepts into different entities. The corrected response is showcased in Listing 2:

Listing 2: Example of a corrected response

```
extracted_object:
  continent: GEO:000000340
  continent_2: GEO:000000342
named_entities:
  - id: GEO:000000340
    label: Africa
  - id: GEO:000000342
    label: Europe
```

While this approach deals with a high percentage of this type problem, it does not cover the cases where more than three same-class concepts are inside the piece of text being analyzed.

6 CONCLUSIONS

Using OntoGPT in the Graph Massivizer strategic foresight project will prove valuable for enriching causal graphs with linked ontology data, aiming to improve predictive accuracy in predicting future events. Despite OntoGPT's initial focus on medical data, some custom adaptations were successfully implemented to suit a portion of different domains. However, limitations persist in distinguishing between multiple instances of the same concept class. These challenges highlight the need for further development to enhance the tool's versatility across a broader array of applications and ontologies.

Abstract

With the rapid expansion of the computing industry, efficient energy utilization and reduction of CO_2 emissions are critically important. This research develops analytical tools to predict CO_2 emissions from various machine learning processes. We present a novel methodology for data acquisition and analysis of CO_2 emissions during model training and testing. Our results demonstrate the environmental impact of different algorithms and provide insights into optimizing energy consumption in artificial intelligence applications.

Keywords

CO_2 Emissions, Machine Learning, Energy Consumption, Environmental Impact, AI Model Optimization, Green AI, Sustainable Computing, Carbon Footprint

1 Introduction

The global computing industry significantly contributes to CO_2 emissions, with data centers accounting for 2.5 to 3.7 percent of global greenhouse gas emissions [1]. These emissions exceed those of the aviation industry due to continuous operations and heavy reliance on fossil fuels [11]. Given the growing demand for artificial intelligence (AI) applications, there is an urgent need for CO_2-conscious solutions.

This research aims to develop tools for predicting CO_2 emissions associated with machine learning processes, thus enabling the reduction of the environmental impact of AI models. In collaboration with Eviden (Spain) and under the FAME EU project, we have developed a CO_2 emissions analysis system using tools like CodeCarbon [2] and eco2AI [3].

1.1 Research Goals

The primary goal of this research is to develop a service that predicts CO_2 emissions and power consumption of different machine learning models during both training and evaluation phases with emphasis on hyperparameter dependency. The CO_2 emissions are measured in kilograms per second ($\frac{kg}{s}$) , while the power consumption is measured in kilowatt-hours (kWh).

While existing services, such as CodeCarbon [2] or eco2AI [3], provide real-time measurement of emissions, they do not offer insights into a model's emissions before its construction or use. The service we aim to provide addresses this gap by offering an estimation of emissions and power consumption for different models before they are selected for specific use cases. This forward-looking approach allows for more informed decisions when choosing models, potentially reducing their environmental footprint.

2 Related Work

The environmental impact of machine learning models has been a growing concern in recent years. Several studies have focused on quantifying and reducing the carbon footprint of artificial intelligence (AI) processes. For instance, [12] highlighted the energy consumption of training large neural models and suggested methods for minimizing emissions. Similarly, tools like CodeCarbon [2] and eco2AI [3] have emerged to measure real-time CO_2 emissions from computational tasks. However, these tools often lack predictive capabilities for assessing emissions before model selection, as pointed out by. Our work builds on these existing methodologies, concretely on the work of eco2AI[3], by providing a forward-looking approach that estimates emissions during the model selection phase, thus complementing real-time monitoring tools. This is achieved through heavy dependency on eco2AI[3] measuring systems for data collection, later used for modeling based on the collected data and registered hyperparameters.

2.1 Research Gap and Contribution

Despite the growing availability of tools like CodeCarbon [2] and eco2AI [3], a significant gap remains in the preemptive evaluation of environmental impact during the machine learning (ML) model selection phase. The mentioned tools are valuable for post hoc analyses but do not assist ML practitioners in making **informed decisions upfront**—before model development—on the environmental footprint of different model architectures or hyperparameters.

This gap is crucial, as the model selection phase often involves trial-and-error across multiple models and configurations, potentially leading to unnecessary resource consumption. Without predictive capabilities, practitioners have limited insight into which models will have the lowest environmental impact before engaging in resource-intensive training.

Our research aims to fill this gap by introducing a **predictive service** that estimates the environmental footprint of different ML models before they are trained or used. This service leverages the data collected from existing tools like eco2AI [3], incorporating key features such as hyperparameters, and model architecturre into predictive models. By doing so, we enable developers

to make **more sustainable choices** at the model selection stage, reducing carbon emissions from the start of the ML lifecycle.

The table 1 below presents a feature matrix comparing our proposed service with current tools, showing how our approach addresses unmet needs:

3 Methodology

Due to the lack of suitable data on CO_2 emissions of machine learning models, we began by developing an infrastructure for data collection. This infrastructure is composed of the following steps:

- **Dataset Generation:** Creating synthetic datasets using random data generation methods.
- **Data Preprocessing:** Cleaning and preparing the data for analysis.
- **CO_2 Emission Measurement:** Recording CO_2 emissions during both training and testing phases using different machine learning algorithms.
- **Feature Extraction:** Extracting relevant features such as project ID, experiment details, epoch duration, power consumption, and hardware configurations.
- **Adding Hyperparameters to Final Dataset:** Documenting hyperparameters used in each experiment to assess their impact on emissions.
- **Containerization:** Utilizing Docker for containerization to ensure reproducibility and scalability of the experiments.
- **Data Storage:** Storing all datasets, features, and emission records systematically in a database for further analysis.
- **Modeling:** Developing and training machine learning models to predict CO_2 emissions and power consumption.

The software implementation uses Python, with dependencies including pandas [7], scikit-learn [10], matplotlib [5], eco2AI [3], TensorFlow [**abadi2016tensorflow**], Keras [**chollet2015keras**], and Docker for containerization [**merkel2014docker**].

3.1 Dataset Generation

In this step, we created a synthetic dataset by generating random data points using tools like `sklearn.datasets.make_regression` or `make_classification`. The primary objective here is not to reflect real-world data scenarios but to produce a controlled environment where the focus is on measuring CO_2 emissions and power consumption during model training and evaluation. Datasets generated vary in size from ranges of 250 to 15000 samples and 5 to 2000 features. In classification cases additionally the number of classes ranges from 2 to 50. These parameter ranges were selected to mitigate the risk of computational overload, ensuring that the experiments remain feasible within the available computational resources while maintaining the integrity of the analysis.

3.2 Data Preprocessing

Before analysis, the dataset must be cleaned and prepared. This includes handling missing values, normalizing or standardizing data, encoding categorical variables, and splitting the data into training and testing sets. Proper preprocessing ensures that the data is in the optimal format for the models to learn from and minimizes biases that may affect model performance and emission measurements.

3.3 CO_2 Emission Measurement

We measure CO_2 emissions produced during both the training and testing phases of the machine learning models. This involves using tools like eco2AI [3] to track energy consumption and convert it into equivalent CO_2 emissions. The measurements are taken for various models, such as Decision Trees, Random Forests, Logistic Regression, and Neural Networks, to assess their environmental impact under different computational loads.

3.4 Feature Extraction

To gain deeper insights, we extract various features that could impact CO_2 emissions and energy consumption. These features include project identifiers, detailed descriptions of each experiment, the duration of each training epoch, power consumption metrics, hardware configurations (such as the type of CPU/GPU used), and hyperparameters. The project identifiers refer to unique alphanumeric codes assigned to each machine learning experiment upon execution. These identifiers help differentiate between various model configurations and experimental setups. They are generated and stored automatically by our system during the dataset generation process to ensure traceability and reproducibility of the experiments.

3.5 Adding Hyperparameters to Final Dataset

We document the hyperparameters used in each machine learning experiment, such as learning rates, batch sizes, and the number of layers in neural networks. This allows us to evaluate how these hyperparameters influence CO_2 emissions and energy consumption.

3.6 Containerization

To ensure reproducibility and scalability of our experiments, we employ Docker for containerization. This approach encapsulates the code, dependencies, and environment settings, allowing the experiments to be easily replicated and deployed across different platforms.

3.7 Data Storage

All datasets, extracted features, hyperparameter configurations, and CO_2 emission records are systematically stored in a database. This central repository facilitates efficient querying, retrieval, and analysis of data to support ongoing and future research.

3.8 Modeling

In this step, we develop and train machine learning models to predict CO_2 emissions and power consumption based on various features, such as the type of algorithm used, hardware configuration, and model parameters. This modeling allows us to estimate emissions for different machine learning workflows before their actual deployment. The models help identify the most efficient algorithms and configurations, thus guiding the selection of environmentally friendly AI solutions.

The general pipeline for the previously mentioned steps can be seen below (see Figure 1).

A more thorough view of the workings of this can be seen as shown below for running a single measurement (see Figure 2).

4 Model Architecture

In this section, we explain the architecture of the model used for predicting CO_2 emissions and power consumption based on

Tool/Technology	Platform Compatibility	Model Coverage	Metric Granularity	Carbon Metrics	Energy Metrics	Additional Features	Real-time measurement	Forward-looking Prediction
CodeCarbon	Cloud, On-Premise	All ML models	Per training session	CO_2 emissions (kg)	Energy consumption (kWh)	Dashboard Visualization	Yes	No
eco2AI	Cloud, On-Premise	All ML models	Per training session	CO_2 emissions (kg)	Energy consumption (kWh)	Not RAPL based	Yes	No
Proposed Service	On-Premise	Specific models (mentioned bellow)	Per model, per selection phase	CO_2 emissions $\frac{kg}{s}$	Energy consumption (kWh)	Predictive modeling	No	Yes

Table 1: Feature comparison of existing tools and the proposed service

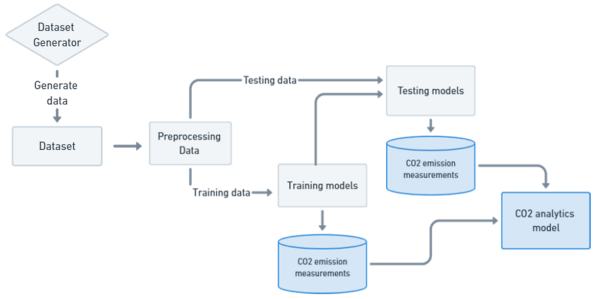

Figure 1: General Measurement Pipeline

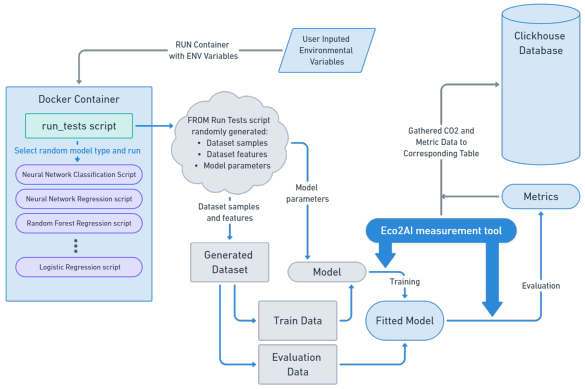

Figure 2: Single Model Measurement Pipeline

various features such as CPU type, GPU type, region, and other experiment-specific details. The model implementation is encapsulated within a Python class named `MultiModel`, which is responsible for managing the entire process from data preprocessing to training and prediction.

The model employs two separate neural networks for predicting CO_2 emissions and power consumption. The architecture for each neural network is as follows:

- **Input Layer:** Receives the scaled and encoded features.
- **Hidden Layers:** Consist of multiple Dense layers with ReLU activation functions. The CO_2 emissions model includes three hidden layers with 128, 64, and 128 neurons, respectively, while the power consumption model has three hidden layers with 64, 64, and 128 neurons.
- **Output Layer:** A single neuron that outputs the predicted value for either CO_2 emissions or power consumption.

4.1 Model Training

The model is compiled using the Adam optimizer [6] and the Mean Squared Error (MSE) loss function. Seeing as we were unable to gather adequate real-time environmental data of factors that may influence our predictions (e.g. Distribution of energy sources, real time CO_2 per kWh), our model relies on static yearly averages of these values[8] [9] . Our model uses the aforementioned features for the purpose of regression with the goal of predicting power consumption and CO_2 emissions gathered by previously mentioned random tests. Each model is trained for 25 epochs using the preprocessed data. After training, the models, along with their respective scalers and encoders, are saved to disk for later use.

4.2 Prediction

Once trained, the model can predict CO_2 emissions and power consumption for new data points by loading the appropriate model, scaler, and one-hot encoder. The input data is preprocessed in the same manner as during training, and the predictions are obtained by applying the trained models.

This modular approach allows for easy extension to additional models or data sources and provides a scalable solution for analyzing the environmental impact of machine learning processes.

5 Web Application Interface for CO_2 Emissions and Power Consumption Prediction

In addition to the backend model developed for predicting CO_2 emissions and power consumption of various AI models, a web application was created to provide a user-friendly interface for real-time predictions. The web app, as shown in Figure 3, allows users to select different machine learning models and configure parameters to estimate the associated environmental impacts.

5.1 Key Features of the Web Application

The web application interface is designed with simplicity and functionality in mind. It includes several key components:

- **Model Selection:** Users can choose the type of machine learning model they are interested in evaluating (e.g., Logistic Regression (abbr. LogR), Decision Tree Classifier (abbr. DTC), Decision Tree Regression (abbr. DTR), Neural

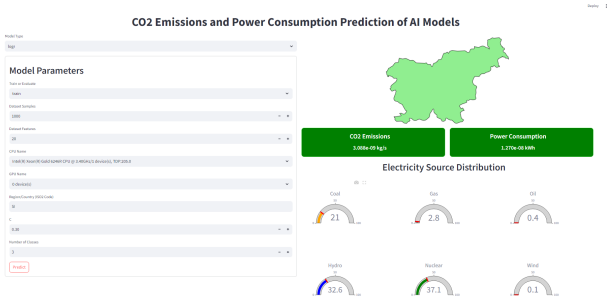

Figure 3: Web App Interface

Network Classifier (abbr. NNC), Neural Network Regression (abbr. NNR), Linear Regression (abbr. LinR), Random Forest Classifier (abbr. RFC) and Random Forest Regression (abbr. RFR)). The dropdown menu in the upper-left corner of the interface provides a list of available models.

- **Model Parameters Configuration:** A section labeled "Model Parameters" allows users to specify various inputs:
  - **Train or Evaluate:** Users can choose whether to estimate emissions for the training or evaluation phase of the model.
  - **Dataset Samples and Features:** Input fields are provided for users to define the size of the dataset in terms of the number of samples and features.
  - **CPU and GPU Specifications:** The app allows the selection of the CPU and GPU type, reflecting different hardware configurations, such as "Intel(R) Xeon(R) Gold 6246R CPU @ 3.40GHz/1 device(s), TDP:205.0" or "AMD Ryzen 7 4800H with Radeon Graphics/1 device(s), TDP:45.0".
  - **Region/Country Selection:** A dropdown to select the geographic location where the model is being executed, which influences the CO_2 emissions based on local energy sources.
- **Real-Time Predictions:** Once all parameters are configured, the application dynamically calculates and displays:
  - **CO_2 Emissions:** The predicted emissions are shown in kilograms per second (kg/s).
  - **Power Consumption:** The power consumption is provided in kilowatt-hours (kWh).
- **Electricity Source Distribution:** A graphical representation is provided for the distribution of electricity sources, such as coal, gas, and oil, in the selected region. This information is crucial for understanding the environmental impact of power consumption based on the local energy mix.

5.2 User Experience and Accessibility

The web application is developed with accessibility in mind, ensuring that users, regardless of technical background, can interact with the model's predictive capabilities. By offering a clear and intuitive interface, it aims to make the process of estimating CO_2 emissions and power consumption transparent and straightforward.

Figure 3 illustrates the application's main screen, where the model type, parameters, and results are all visible at a glance. This real-time feedback loop allows users to make informed decisions based on the predicted environmental impact.

6 Results

6.1 Model Error

To evaluate the performance and accuracy of the models, we conducted a 10-fold cross-validation to estimate the errors in predicting CO_2 emissions and power consumption. The results are presented in Table 2. The errors for both CO_2 emissions and power consumption were computed for both training and evaluation phases of each model type.

Note: In this context, "Train." refers not to the error on the training set, but rather to the error made by our model in predicting the CO_2 emissions / Power Consumption during the training phase of the listed model. Similarly, "Eval." refers not to the error on the evaluation set, but rather to the error made by our model in predicting the CO_2 emissions / Power Consumption when the listed model makes predictions. This distinction is crucial to understanding the results accurately.

Table 2: Model Scaled Error Estimates from 10-Fold Cross-Validation

Model	Phase	CO_2 Error	Power Error
DTC	Eval.	0.0036	0.0043
DTC	Train.	0.0631	0.0649
DTR	Eval.	0.0032	0.0034
DTR	Train.	0.0133	0.0517
RFC	Eval.	0.0094	0.0098
RFC	Train.	0.3242	0.3582
RFR	Eval.	0.0087	0.0081
RFR	Train.	0.2565	0.2779
LogR	Eval.	0.0063	0.0057
LogR	Train.	0.0055	0.0043
LinR	Eval.	0.0099	0.0105
LinR	Train.	0.0104	0.0095
NNC	Eval.	0.0018	0.0030
NNC	Train.	0.1083	0.1216
NNR	Eval.	0.0045	0.0112
NNR	Train.	0.1051	0.1008

Based on the results obtained through the 10-fold cross-validation, it is evident that the model performance varies significantly across different algorithms and phases. One notable observation is that the errors in predicting CO_2 emissions and power consumption are relatively higher during the training phases, particularly for more complex models like Neural Networks and Random Forests [4].

This discrepancy in model performance can be attributed to the sparsity of the data collected during the measurement phase. The limited data points lead to substantial gaps in the attribute space covered by the models, resulting in erratic behavior when predicting outside these ranges. Consequently, the models show diminished accuracy and reliability when confronted with input configurations that fall beyond the scope of the original data.

Future research should focus on enhancing the robustness of these models by expanding the dataset to include a broader range of scenarios and conditions. This would help mitigate the effects of sparsity and improve the model's generalizability, ensuring more reliable predictions across diverse settings.

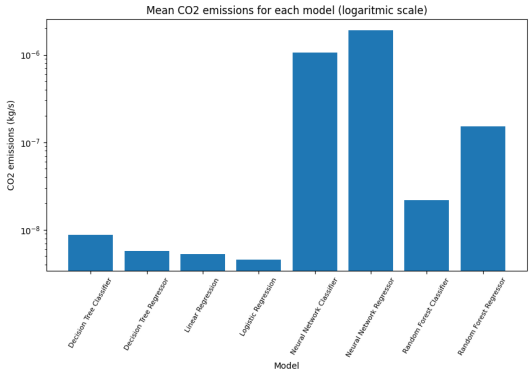

Figure 4: Logarithmically scaled mean emissions across different models

6.2 CO_2 Emission Analysis Across Different Models

Figure 4 provides a comparative analysis of the mean CO_2 emissions generated by different machine learning models during their operation, represented on a logarithmic scale to accommodate the wide range of emission values.

The chart highlights significant variations in CO_2 emissions among models, with the Neural Network Classifier and Neural Network Regressor exhibiting the highest emissions by a considerable margin. This is expected due to the intensive computational requirements and numerous parameters these models necessitate, resulting in elevated power consumption and consequently higher CO_2 output.

In contrast, simpler models like Logistic Regression, Linear Regression, and Decision Tree models show substantially lower CO_2 emissions, reflecting their reduced computational complexity and lower resource demand.

Interestingly, the Random Forest models, particularly the Regressor, present moderate emissions, illustrating that even ensemble methods, which typically involve training multiple decision trees, can maintain reasonable emission levels depending on their configuration.

This analysis underscores the importance of model selection not only for performance but also for minimizing environmental impact, particularly when scaling up operations or deploying in resource-constrained settings.

7 Discussion

The results highlight the significant environmental impact of training complex AI models, particularly neural networks. The variability in emissions suggests that optimizing model hyperparameters and selecting appropriate hardware configurations can reduce CO_2 output.

Future research should focus on model improvement for better and more accurate prediction, expanding the range of algorithms studied, as well as intensive data collection to accommodate gaps in training data.

8 Limitations

This study presents several limitations, particularly regarding the data, model evaluation, and hardware configurations, which must be considered when interpreting the results.

8.1 Training Duration and Model Learning

The models were trained for a fixed number of epochs (e.g., 10 or 20), prioritizing computational cost over learning performance. The focus was on estimating CO_2 emissions rather than model accuracy or convergence, meaning the models may not have fully captured patterns in the data. As such, the reported emissions reflect standardized training durations (with an upper limit for computational efficiency), not optimized learning outcomes.

8.2 Lack of Meaningful Learning Objective

The use of randomly generated data limits the evaluation of model learning. Since the data lacked inherent structure, the models' ability to learn was not assessed. Instead, the models were primarily evaluated on their resource consumption during training, reducing the focus on generalization or predictive power.

8.3 Hardware and Software Considerations

The experiments were conducted on specific hardware (e.g., GPU/CPU configurations), and variations in hardware were not examined. Different hardware setups, especially energy-efficient systems, could significantly impact CO_2 emissions and energy consumption. Therefore, the findings may not generalize across all hardware environments. However, we would like to point out that this was due to lack of infrastructure for broader experimentation.

9 Future Work

Future research should incorporate real-world datasets, optimize hyperparameters, and evaluate diverse hardware configurations to extend these findings to broader machine learning scenarios. The exploration of more complex architectures and learning objectives will provide a deeper understanding of the trade-offs between performance and environmental impact.

10 Conclusion

Our study presents a methodology for monitoring and analyzing CO_2 emissions during machine learning processes. The findings demonstrate that different machine learning models exhibit significant variability in their energy consumption and CO_2 emissions, with complex models like neural networks having a higher environmental impact. By providing predictive insights into these emissions, our approach enables more informed decision-making during model selection, thus contributing to the broader goal of reducing the carbon footprint of AI applications.

Future work will focus on expanding the dataset to include more diverse models and configurations. Additionally, we plan to integrate real-time monitoring tools to compare predictions with actual emissions, further refining our predictive capabilities. Moreover, optimizing model hyperparameters and exploring alternative, more sustainable hardware configurations will be key areas of investigation for minimizing the environmental impact of machine learning workflows.

Abstract

This paper explores the use of LLMs in ontology engineering within the HumAIne project, focusing on the discovery, analysis, and extension of ontologies in Data Mining, Machine Learning, and manufacturing. The methodology leverages fine-tuned prompts and combines LLMs with traditional tools like Protege for validation. A multi-LLM approach improved domain-specific concept coverage and reduced errors, though challenges remain in addressing deep domain-specific gaps and ensuring logical consistency.

Keywords

LLMs, Ontology Engineering, Active Learning, Data Mining, Machine Learning, Ontology Selection, Ontology Extension

1 Introduction

The HumAIne project, funded by the European Commission under the Horizon Europe program, aims to develop a platform integrating advanced AI paradigms such as Active Learning (AL), Neuro-Symbolic AI, Swarm Learning, and Explainable AI. This platform is designed to enhance human-AI collaboration in dynamic, unstructured environments, with applications spanning healthcare, manufacturing, finance, energy grids, and smart cities. Its primary goal is to support decision-making by combining human expertise with AI capabilities.

One of the project's key challenges is developing multiple ontologies that provide a structured framework for integrating domain-specific knowledge. This framework is essential for enhancing the clarity and reliability of AI-driven decisions, while ensuring adaptability across diverse applications. To construct these ontologies, we first explored publicly available ontologies relevant to the project's scope, then extended selected ones with concepts from HumAIne's AI paradigms, starting with Active Learning

However, manual ontology construction is a complex, resource-intensive process that requires expertise across multiple domains, collaboration among stakeholders. Ensuring modularity, reusability, and scalability adds to this complexity.

Recent studies show that leveraging Large Language Models (LLMs) can streamline ontology construction by reducing manual effort and improving consistency and quality. For instance, [1] demonstrates semi-automatic knowledge graph construction using open-source LLMs, while [2] proposes methods for automatic concept hierarchy generation through LLM queries. Building on this research, this paper contributes a methodology that integrates LLMs with traditional tools like Protege to streamline the discovery, analysis, and extension of ontologies. By employing a multi-LLM approach, we address challenges in domain-specific concept identification and ensure more consistent, accurate results in ontology development for fields like Data Mining, Machine Learning, and manufacturing.

2 LLM-Assisted Search and Analysis of Domain Ontologies

Our experimentation with methodologies and tools for efficient web search and ontology analysis in Data Mining (DM), Machine Learning (ML), and manufacturing domains led to the development of the LLM-leveraging algorithm shown in Fig. 1. This algorithm uses carefully crafted prompts to guide LLMs in generating accurate, targeted queries. Before each step, the initial prompt is optimized through several iterations in a dialogue with the LLM to improve accuracy and relevance. Further details on the iterative query refinement process are provided in the Discussion section.

Step 1: Define the Search Objective. At this stage, LLMs like Bing Chat, Google's Bard, or ChatGPT with Web Browsing are employed to iteratively refine the search objectives initially formulated by the researcher, along with relevant keywords, phrases, and terms describing the ontologies or concepts of interest. For instance, our initial search objective for DM and ML ontologies was to "Find ontologies that offer up-to-date, detailed descriptions of the DM and ML domains, following best practices in ontology engineering." Keywords included "Active Learning" and "CRISP-DM standard."

Step 2: Formulate Search Queries Using LLMs. Based on the refined search objectives and keywords, and using a carefully crafted prompt, LLMs generate targeted search queries. These queries are fine-tuned through feedback or early search results to maximize relevance and accuracy. For example, for a DM ontology, the LLM generated queries such as "Data Mining ontology for semi-supervised machine learning," which were further refined before finalizing the query.

Step 3: Conduct Web Search. This step involves real-time browsing tools like Copilot in Microsoft Edge (GPT-4) and Perplexity AI to execute searches and identify relevant sources. Our study prioritized high-quality sources like ontology

repositories (e.g., BioPortal, OBO Foundry) and academic databases (Google Scholar, IEEE Xplore, ACM Digital Library).

It is important to acknowledge that LLM-driven web searches are generally confined to public repositories and a limited range of academic databases. As a result, proprietary or lesser-indexed ontologies may require manual exploration to ensure a more thorough search.

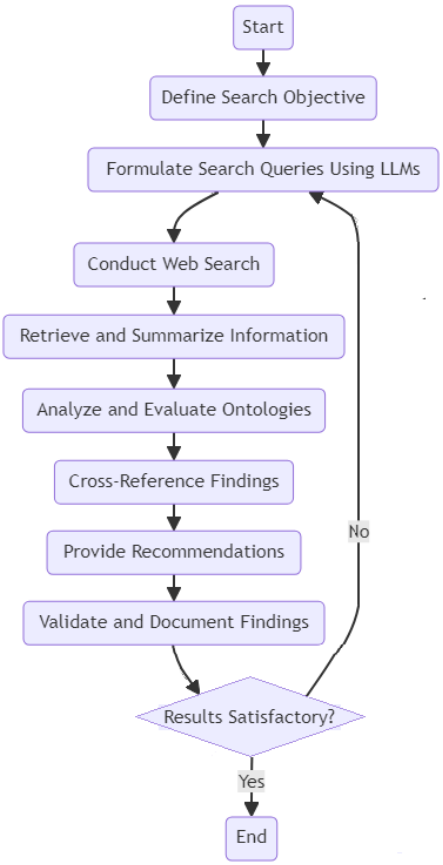

Figure 1: Key steps of LLM-leveraging algorithm

Step 4: Retrieve and Summarize Information. LLMs (Google Bard, Copilot (GPT-4), Perplexity AI) were employed to extract and summarize key information from ontology descriptions found in publications, technical papers, and repository documentation identified during the search. Using a specifically tuned prompt, LLMs extracted 11 characteristics for each of the 34 identified DM and ML ontologies. These characteristics included purpose, availability, ontology metrics, reused ontologies, software editors, representation language, and evaluation methodologies. This structured data, organized in table format, provided valuable insights into each ontology's scope, quality, and reusability. From these results, we selected 6 ontologies for further exploration, prioritizing comprehensive coverage of DM and ML concepts, adherence to ontology engineering best practices, and alignment with established standards in these domains.

Step 5: Analyze and evaluate ontologies. LLMs were further utilized to assess the relevance, content, and structure of the selected ontologies. In our study of DM and ML ontologies, LLMs such as GPT-4, which can process, explain, and generate OWL and RDF code, were used alongside ontology tools like Protege. This combination ensured that the ontologies addressed relevant concepts and aligned with frameworks like CRISP-DM. GPT-4 helped significantly in bridging the gap between textual descriptions and formal ontology representations.

Step 6: Cross-Reference and Compare Findings. LLMs with contextual understanding were employed to integrate and refine information from multiple sources. For this task, we used. Additionally, ChatGPT (GPT-4) categorized 65 manufacturing ontologies categorized 65 manufacturing ontologies, assessing them for relevance to process planning, standardization, industry adoption, interoperability, and support for advanced manufacturing concepts. Further exploration of the top 8 LLM-scored ontologies showed strong alignment with expert evaluations, but domain-specific tasks required carefully crafted prompts and human oversight for effectiveness.

Step 7: Provide Recommendations for Further Exploration. LLMs generated recommendations for the most suitable ontologies or areas for additional research based on the previous step's results. This includes identifying underexplored concepts and areas needing further investigation.

Step 8: Validate and Document Findings. The findings were manually validated for accuracy and relevance, then systematically documented. ChatGPT (GPT-4) was used to summarize and structure the documentation.

Step 9: Iterate and Refine Search (if needed). When results were too broad or irrelevant (e.g., Active Learning misinterpreted as an educational method), we refined the search prompt by adding more context.

By using this LLM-based algorithm, we conducted comprehensive web searches and extracted relevant information to identify the most suitable ontologies for the HumAIne project. In the DM and ML domains, we selected the OntoDM suite (OntoDM-Core, Onto-KDD, and OntoDT). For the manufacturing domain, we identified the Industrial Ontologies Foundry Core (IOF Core) as the best fit.

3 LLM-Assisted Ontology Extension with Active Learning Concepts

Integrating Active Learning (AL) into an ontology requires extending it with new classes, properties, and relationships representing key AL concepts. While traditional methods of building and extending ontologies are well-documented, we leveraged GPT-4 for this task using iteratively refined prompts (see Discussion section). This section outlines how LLMs, particularly GPT-4, were used to extend the IOF Core ontology with AL concepts.

Step 1: Define the Problem and Objectives. Through iteratively refined prompts, LLMs formulated clear objectives, specifying the domain (e.g., manufacturing) and key concepts (e.g., Active Learning). These outputs were used to guide further steps, with LLMs leveraging contextual understanding, knowledge synthesis, and language generation to suggest relevant AL applications such as adaptive scheduling. Queries like "How can Active Learning improve adaptive scheduling in manufacturing?" generated valuable insights into potential use cases. where AL would be most beneficial.

Step 2: Analyze the Ontology to be Extended. By combining Protege's visualization and navigation tools with GPT-4's ability

to process textual and machine-readable data (e.g., OWL/RDF), we thoroughly examined the IOF Core ontology structure and identified areas for introducing AL concepts. For example, GPT-4 helped uncover key classes like “Process,” “Resource,” and “PerformanceMetric” within IOF Core, highlighting relevant properties for AL integration. Queries such as "What aspects of IOF Core can benefit from AL integration?" and "What key concepts are missing from the IOF Core ontology for integrating Active Learning in manufacturing?" guided us in identifying areas for improvement, including handling uncertainty and adjusting dynamic processes.

Step 3: Identify Active Learning Concepts. The main tasks of this step and the role of LLMs in supporting each task are summarized in the Table 1:

Table 1: LLMs applications for Identifying AL Concepts

Task	LLM Application	Example Output
1. Identify fundamental AL concepts	Use LLMs to generate a list of core AL strategies and techniques	Concepts like“Uncertainty sampling,” “Query-by-committee”
2. Extract domain-specific AL concepts	Query LLMs about AL in specific industrial contexts	Concept like "Query Efficiency" in decision-making for manufacturing
3. Mine AL concepts from literature	Process academic papers, reports to extract relevant AL terms	Concepts like “Stream-base selective sampling” from papers on AL in manufacturing
4. Assign properties to new classes	Generate properties for AL ontology classes	QueryStrategy class properties: “hasuncertaintySampling” “queryByCommittee”
5. Refine and validate terminology	Ensure definitions, resolve overlaps	Refined and validated terms based on domain-specific standards

By prompting, LLMs generated nearly 200 fundamental AL concepts, structuring them into a hierarchy by leveraging their vast training data. Additionally, LLMs helped generate definitions, assisting in verifying and refining concepts. However, after a point, LLMs began repeating concepts or producing less relevant terms. LLMs were also effective in generating domain-specific concepts through targeted queries. For instance, querying AL in manufacturing led to concepts like "uncertainty management" and "query efficiency." More specialized concepts required extraction from academic papers, which were cross-referenced with existing standards in DM, ML, and manufacturing (e.g., CRISP-DM, IEEE 7000 Series, ISA-95, ISO 15531). Ontology learning tools like Text2Onto and OntoLearn were combined with LLMs for cross-verification.

*Step 4: Develop Ontology Extensions.*LLMs helped create AL-related classes, properties, and relationships based on the identified concepts, using OWL-compliant syntax (see Fig. 2). By combining GPT-4’s knowledge synthesis with Protege’s structural reasoning and consistency checking, we improved the efficiency and accuracy of reviewing, debugging, and validating OWL code.

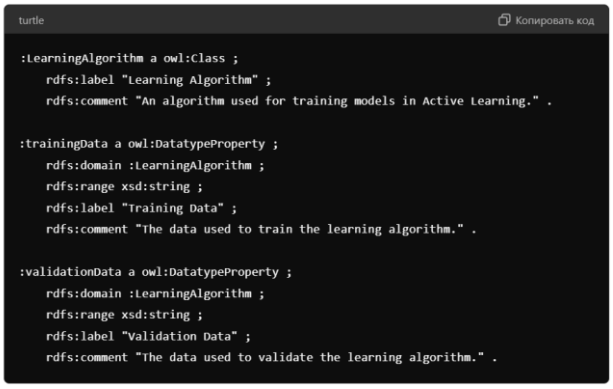

Figure 2: Screenshot of LLM-generated code defining the “LearningAlgorithm” class with properties “trainingData” and “validationData”

Step 5: Ensure Semantic Consistency. LLMs, such as GPT-4, assisted in ensuring semantic consistency by reviewing new and existing ontology elements and suggesting how new concepts could align with the existing framework. For example, an LLM suggested how an AL “QueryStrategy” class fits within the IOF Core ontology.

Example Prompt: " Review the new QueryStrategy class and suggest how it can align with the existing classes in IOF Core."

LLM Output: The QueryStrategy class aligns with decision-making aspects of the Process concept. Strategies such as “UncertaintySampling,” “QueryByCommittee,” “ExpectedModelChange,” and “ExpectedErrorReduction” can be viewed as specialized decision-making processes within the broader process framework of IOF Core.

However, LLMs cannot guarantee logical consistency and face limitations in handling complex relationships, making it necessary to use ontology reasoners, such as Protege or HermiT, to perform consistency checks.

Step 6: Map to Existing Ontologies. LLMs, such as GPT-4, assist in generating initial mapping suggestions by analyzing similarities in definitions, relationships, and properties between new and existing concepts. This involves creating explicit relationships like “owl:sameAs,” “owl:equivalentClass”, and “owl:equivalentProperty”.

Example LLM Output:

:FeedbackMechanism a owl:Class ;
owl:equivalentClass :ControlSystem ;
rdfs:label "Feedback Mechanism" ;
rdfs:comment "Mechanisms that provide feedback in Active Learning to control systems."

While LLMs are effective in identifying high-level similarities, they may face challenges with complex or domain-specific relationships, requiring further refinement. Although we didn’t encounter these issues during our initial work extending IOF Core with AL concepts, we used Protege’s alignment plug-ins to refine LLM-generated mappings. For more complex mappings, tools like AgreementMaker or COMA can further refine the suggestions.

Step 7: Prototype and Test. LLMs, such as GPT-4, were prompted to generate validation scenarios, competency questions, and SPARQL queries based on the integrated AL concepts. For instance, a prompt like "Suggest validation scenarios for adaptive scheduling with Active Learning" helped us produce realistic test cases, including prototype code, descriptions of initial setup, process flows, validation steps, and queries based on newly integrated concepts.

SPARQL queries generated by LLMs were executed using Protege with SPARQL plugins to assess the ontology's ability to retrieve relevant information and answer competency questions.

However, some LLM-generated scenarios revealed limitations in domain-specific knowledge, resulting in generic outputs that required refinement. Additionally, LLMs struggled with modeling intricate relationships or complex data retrieval conditions, making human oversight essential for ensuring accuracy and thorough testing.

Step 8: Iterative Refinement. Following initial prototyping and testing, we gathered feedback from domain experts and users to further refine the ontology. Validation reports were uploaded to AskPDF Research Assistant (GPT-4), where LLMs reviewed the reports, extracted key improvement suggestions, and refined task lists. The LLM provided insights into areas where ontology relationships or properties required adjustments and identified additional concepts that might have been overlooked.

Step 9: Document and Disseminate. LLMs like ChatGPT or Bard were instrumental in generating comprehensive documentation, including details on the ontology extensions. Additionally, LLMs contributed to drafting technical reports and research papers.

Using this methodology, we successfully extended the IOF Core ontology with Active Learning (AL) concepts. Future stages of the HumAIne project will focus on further validation and refinement, particularly during pilot case implementations.

4 Discussion

This study highlights LLMs' potential in ontology engineering by reducing manual effort and increasing efficiency. LLMs rapidly identified key ontologies like OntoDM and IOF Core and generated structured classes, properties, and relationships, reducing the need for manual OWL/RDF code generation and concept mapping. However, LLMs face challenges in domain-specific precision, requiring human oversight to refine outputs and address nuances in specialized fields. While tools like Protege excel at ensuring logical consistency, LLMs offer dynamic capabilities for generating new concepts and relationships. Despite these advantages, traditional tools like AgreementMaker and COMA are still necessary to refine and validate LLM-generated mappings.

One strategy to mitigate LLM limitations was iterative prompt engineering. We refined prompts for ontology search and extension tasks through multiple cycles of improvement. These cycles, with LLMs like GPT-4, involved clarifying questions, refining queries, and generating more focused outputs. Initial prompt for starting the cycle can be the following:

"Your role is my Prompt Creator. Your goal is to craft the best possible prompt for my needs. The prompt will be used by you, [LLM's name]. I want to write about: [keyword/topic]. Based on my input, you will now generate 3 sections. a) Revised prompt (clear, concise, and easily understood by you), b) Suggestions (on what details to include in the prompt to improve it), and c) Questions (ask any relevant questions to improve the prompt). We will continue this iterative process with me providing additional information to you and you updating the prompt until it's complete."

After 4-5 cycles, the prompts were highly optimized, ensuring relevant outputs. This refinement process reduced inconsistencies and improved LLM-generated content across both search and extension phases.

We integrated multiple LLMs, including Bing Chat (GPT-4), Google's Bard, and Perplexity AI, to cross-validate outputs, reducing errors and refining results. This ensured consistency in LLM-generated ontologies and mappings.

To evaluate this multi-LLM approach, we propose the following metrics: Inter-Model Consistency (measures alignment between LLM outputs). Error Rate Reduction (Tracks how often one LLM corrects another's errors),.Coverage of Relevant Concepts (assesses LLMs' ability to capture domain-specific concepts). Although these metrics provide a framework, formal measurements are yet to be implemented.

Future stages will involve applying these metrics to validate outputs and testing extended ontologies in real-world applications. This hybrid method combines LLMs and traditional tools, ensuring both efficiency and accuracy in scalable ontology development.

5 Conclusions

This study demonstrates how LLMs can streamline ontology engineering by automating the search, analysis, and extension of domain-specific ontologies. Leveraging multiple LLMs, we successfully identified and extended key ontologies, including OntoDM and IOF Core, for the HumAIne project, improving efficiency in generating classes, properties, and relationships.

While LLMs significantly enhance the process, they face challenges in domain-specific precision and require human oversight, particularly for complex relationships. Traditional tools like Protege and ontology reasoners remain critical for ensuring logical consistency and validation.

Future work will focus on refining these extended ontologies through real-world pilot tests and applying evaluation metrics to LLM-generated outputs. This hybrid approach, combining LLM automation with traditional validation tools, offers a scalable solution that balances efficiency with the need for human expertise.

Acknowledgments

This work was supported by the European Commission under the Horizon Europe project HumAIne, Grant Agreement No. 101120218.

ABSTRACT

Artificial Artificial Intelligence (AI) is rapidly transforming industries and economies worldwide, with Brazil and South America emerging as significant players in this global shift. The fundamental need to monitor the impact of artificial intelligence (AI) in the verticals for sustainable development, government engagement, investment and society at large motivated the Brazilian Artificial Intelligence Observatory (OBIA). It is also an integral part of the Brazilian Artificial Intelligence Plan (PBIA), and a former objective of the Brazilian Strategy of AI aims to become the leading platform for monitoring the uses of AI in the country. OBIA is part of Axis 5 of the PBIA focused on supporting the regulatory and governance process of AI. This research paper explores the current state, challenges, and potential of AI development in the region, examining how technological advancements are influencing economic growth, societal change, and policy-making across South America, with a particular focus on Brazil as a leading hub of innovation. It is also investigating common aspects of the research agendas as with IRCAI's SDG Observatory, particularly in what regards machine learning workflows and approaches complementing traditional and crowdsourced heterogeneous data collection and analysis.

KEYWORDS

Artificial Intelligence, Observatory, Survey Data Analysis, Complex Data Visualization, Multidisciplinary Collaboration.

1 Introduction

AI is increasingly shaping the economic landscape and societal dynamics across Brazil and South America, positioning the region as a growing hub for technological innovation. Despite challenges such as uneven infrastructure and regulatory hurdles, Brazil is making significant strides in AI research and development, contributing to the regulation and better understanding of the impact of AI in South America. OBIA [5] is answering this need, serving as a platform to support the strategy and other government actions with data on the uses and impacts of AI (see Figure 1).

Figure 1: Screenshot of OBIA showing some results on the preparedness of Brazilian industry to adopt AI workflows.

The objectives of OBIA include compiling, recording, and providing information related to Artificial Intelligence in Brazil, enabling analyses of its adoption and its main impacts on society. It also has the mission of consolidating and disseminating knowledge about the repercussions of this technology, providing support to guide policies, strategies, and actions in promoting development and responsible use of AI.

The observatory gathers Brazilian data on the use and adoption of Artificial Intelligence by different sectors, such as education, business, government, health, and others (see Figure 2).

The currently available indicators rely mostly on traditional data sources for analysis, such as surveys and data sets made available for the team. The first product of OBIA is the book "Artificial Intelligence in Healthcare - Potentialities, Risks and Perspectives", published in July 2024. In a second line of action, it functions as a repository of guiding documents in the area, originating from all parts of the world. In a third line, it acts as an "information exchange point" between AI centers operating in Brazil: the IAX. All indicators collected will be public and can be accessed on the OBIA portal [4].

The Center for Artificial Intelligence (C4AI) at the University of São Paulo, funded by FAPESP (the public agency for research funding in the State of São Paulo) and IBM, participates in the OBIA through its Humanities area. C4AI will contribute with qualitative research in the horizontal axes of "Legislation, Regulation, and Ethical Use" and "AI Governance," while also conducting studies across various vertical axes to be monitored. The research group dedicated to this effort comprises scholars from the fields of law, computer science, electrical engineering, sociology, and political science, allowing for an interdisciplinary analysis of the key topics monitored by

OBIA. This interdisciplinary approach will provide a comprehensive view of the current state of AI development and implementation in Brazil. Various reports, articles, and data will be provided to support OBIA in fulfilling its mission.

In addition to the participation of professionals from various NIC.br departments, the Observatory has a network of external partners, including the Center for Management and Strategic Studies (CGEE), the São Paulo State System Data Analysis Foundation (SEADE), C4AI, CIAAM (Center of Artificial Intelligence and Machine Learning) and others. The following will explore how C4AI contributes to OBIA through a complementary approach, focusing on the qualitative analysis of decisions by the São Paulo Court of Justice related to AI.

2. Data and Methodology

2.1. Legislation, Regulation, and Ethical Use: A Qualitative Analysis

The research presented in this paper is the base of an action contributing to implement the PBIA strategy [7], responsible for monitoring AI regulation and legislation. It has divided its research into three main areas: the Executive, the Judiciary, and the Legislative branch, combining traditional and modern data collection methods. Regarding the Executive branch, monitoring is being conducted through data scraping of government transparency websites based on a curated and continuously updated list of AI-related terms developed by the group. This monitoring aims to understand what AI systems are being purchased or contracted by public authorities. For the Judiciary, we have been analyzing court decisions from the São Paulo Court of Appeal (TJSP) related to AI, to understand judicial interpretations and rulings in the absence of specific AI legislation [2]. As of the latest data scraping in August 2024, more than 13.000 relevant decisions have been identified. Lastly, in relation to the Legislative Branch, the group is closely following the progress of discussions on Bill 2338/2023, which focuses on AI regulation, by participating in public hearings and issuing technical notes to guide legislators. The goal is to expand this research to monitor AI-related legislation at the state and municipal levels, as many municipalities are legislating on the matter to prepare their cities to assume roles of “smart cities”.

2.2. Monitoring and exploring the local data

To effectively monitor developments in AI, it is essential to establish a comprehensive list of AI-related terms that can guide data collection efforts. This list is derived from multiple sources, including scientific articles, standards like [3], and reports such as OECD's [1]. The monitoring process involves monthly web scraping of court rulings, based on the AI-related terms list, from TJSP (Judiciary Power) and data from the Brazilian Transparency Portal (Executive Power), which occurs on the 15th of each month. For the Judiciary Power, the scrapes and data treatment are performed with scripts developed in Python and R programming languages, based on the TJSP API, by Jesus Filho (github.com/jjesusfilho/tjsp). For the Executive Power, a script was developed to scrape data from the Data Download section of the Brazilian Transparency Portal (portaldatransparencia.gov.br/download-de-dados).

Currently, we are developing an automation tool, based on NLP techniques, to enhance the qualitative analysis of these court rulings, allowing for more efficient identification and categorization of data relevant to AI research. The first approach for this automation tool is using a NER (Named Entity Recognition) model, to automate the identification of relevant entities, including litigants and court judgments. The next step would be to apply a classification model, yet to be chosen, to filter out noise data. The process of constructing the terms for web scraping is a critical step to ensure the relevance and accuracy of the data collected for AI research. This process begins with the development of a comprehensive list of AI-related terms, which is built using multiple authoritative sources. One primary source is the OECD's report "Identifying and Measuring Developments in Artificial Intelligence," which offers a foundation of 226 AI-related terms identified through extensive analysis of scientific articles, open-source systems, and patents. Another source is the ISO/IEC 22989:2022 standard [3], which provides a framework for AI concepts and terminologies. These terms are carefully selected, refined, and translated into Portuguese by experts working within the Brazilian Technical Standards Association (ABNT) to ensure that only those terms that are highly relevant and specific to AI are included. Terms that are too general or contextually irrelevant—such as "transparency," which could result in unrelated hits concerning Brazil's Access to Information Law—are excluded to avoid false positives in the scraping process. The final list of terms, consisting of 103 terms in both English and Portuguese, is used to guide the web scraping data collection processes, allowing a focused and efficient retrieval of information that aligns with specific research objectives.

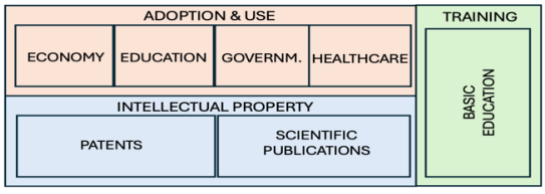

Figure 2: Current Dimensions of OBIA’s monitoring topics

2.3. How to implement and classify repositories with reference documents and statistics?

As part of the data collection and structuring process for qualitative analysis, we are implementing and classifying repositories containing reference documents and statistics. These repositories will focus on key thematic areas, such as "Legislation, Regulation, and Ethical Use" and "AI Governance," and will be populated with data from sources like TJSP, the

Transparency Portal, and other relevant databases. By combining different methods, data retrieval becomes more efficient and targeted, ensuring the collection of relevant information. Web scraping supplements this process by capturing data unavailable through APIs, ensuring comprehensive coverage. The data is regularly updated, with documents classified by relevance to AI terms, creating a dynamic and organized repository (see Fig 3) described in [6].

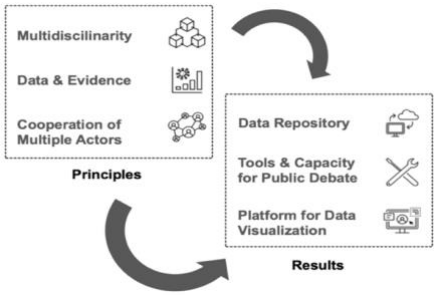

Figure 3: OBIA's guiding principles and expected results [6]

2.4. How to establish and maintain cooperation networks?

Establishing and maintaining cooperation networks requires fostering collaboration among interdisciplinary researchers from fields such as law, computer science, engineering, sociology, and political science. These networks are essential for sharing insights and methodologies related to AI monitoring. Using APIs and web scraping tools enables access to current data, supporting continuous knowledge exchange. Regular workshops, webinars, and joint research projects help keep participants engaged. Publishing reports, articles, and datasets strengthens the network and supports OBIAs mission to monitor AI developments comprehensively.

3 Discussion of initial results

As of June 28, 2024, a total of 13,064 decisions were scraped from the São Paulo State Court of Justice based on AI-related terms. Out of 103 terms searched, 45 returned at least one result. Graph 1 shows the monthly distribution of all results, while Figure 5 (logarithmic scale) displays the distribution of results by AI term. Both Portuguese and English terms were used for scraping. The top 15 terms with the most occurrences were analyzed over time, and Figure 6 presents the temporal evolution of these results by publication date. A qualitative review of 597 decisions from the São Paulo Court of Justice (TJSP) using a detailed list of AI-related terms, focused on terms like "Facial Recognition" and "Facial Biometrics," showing they are often used in various legal contexts, sometimes diverging from their technological meanings.

Terms like "Facial Expression Recognition" and "Learning Agent" were often interpreted in psychological or social contexts rather than purely technological ones. The analysis used analytical, comparative, and monographic methods, with the latter focusing on case-specific factors to draw broader generalizations. From TJSP's website, 597 rulings were reviewed: "Facial Recognition" (1), "Facial Expression Recognition" (1), "Machine Learning" (7), "Artificial Intelligence" (163), "Artificial Intelligence" in English (4), "Machine Learning" in Portuguese (3), "Learning Agent" (1), and "Facial Biometrics" (417).

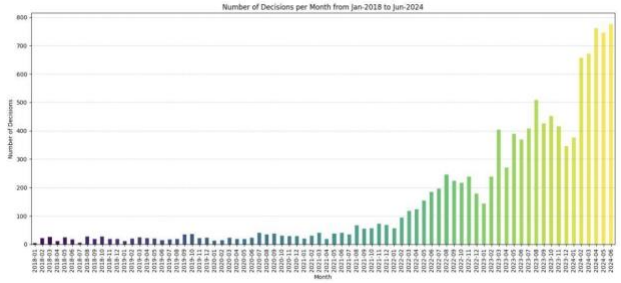

Figure 4: Nr. of Decisions per Month from Jan 2018 to Jun 2024.

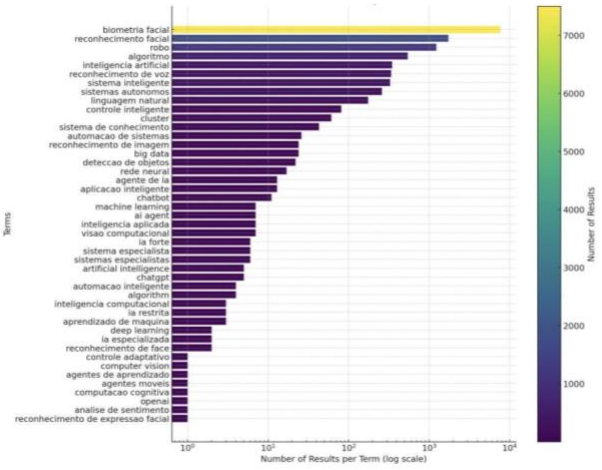

Figure 5: Number of results per AI term.

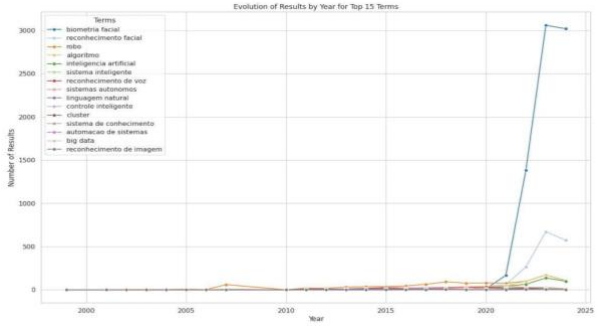

Figure 6: Evolution of results by year for top 15 terms.

The rulings followed a structured format, and the analysis included 14 categories, such as case number, appeal type, judge, district, and the context of term usage. Key findings highlighted the use of "Artificial Intelligence" and "Machine Learning" in commercial disputes and credit issues rather than solely technological matters. The rulings analyzed represent

decisions, rendered by collegiate bodies composed of multiple magistrates. Each ruling follows a structured format: Description and Qualification, covering aspects such as appeal, case number, judicial district, presiding judge, and parties involved; Summary of the ruling; Report, offering a brief description of the facts; Majority Opinion; and Dissenting Opinion (if applicable). The analysis was conducted with each of the 14 subcategories corresponding to columns in a single row: case number; type of appeal; reporting judge; district; judicial body; subject matter; judgment date; publication date; summary; parties; reasoning; final decision; context of term usage in the full text; and relevant jurisprudence. While the first nine categories were predefined based on the complete jurisprudence search, the remaining five were more subjective, created to enhance the understanding of the rulings' content and improve data visualization. Significant findings were noted in cases involving "Artificial Intelligence" and "Machine Learning," where the terms were often associated with commercial disputes, service contracts, or credit-related issues rather than purely technological applications. A recurrent theme in cases involving "Facial Biometrics" was the legality and validity of loan contracts signed through biometric recognition. The majority of decisions upheld the legality of such contracts, highlighting issues of consent and the technical reliability of biometric systems [1]. However, inconsistencies in judicial reasoning were identified, where similar cases had varying outcomes depending on the presiding judge. Overall, the analysis highlighted several gaps and challenges in the legal treatment of AI-related technologies, particularly concerning transparency, fairness, and consumer protection. The study underlined the need for more consistent legal standards and better understanding among judges of the technical nuances involved in AI applications to ensure fair and equitable rulings.

4 Conclusions and further work

The qualitative research findings from the analysis of court decisions related to AI reveal several key conclusions. AI-related terms such as "Facial Recognition," "Voice Recognition," and "Autonomous Systems" are frequently used in judicial contexts that extend beyond their traditional technological meanings, intersecting with areas like consumer protection, contract law, and fraud. The inconsistency in judicial reasoning and varying outcomes in similar cases highlight the need for clearer legal frameworks and a deeper understanding of AI's technological implications among judges. Moving forward, the incorporation of NLP techniques into the analysis will help extract key arguments from judicial decisions, providing deeper insights into the legal discourse on AI. This will enhance the robustness of future research on AI regulation and its implications for public policy.

Furthermore, a preliminary analysis of news using the NLP capabilities of the *Eventregistry.org* system (see Figure 7) show how this source can provide complementary results to the study when, e.g., capturing the attention of media on the terms "criminal law" and "AI" in "Brazil" in the past 12 months, where 1.4% exhibits discussions on Human Rights, and terms like "democracy" and "discrimination" are within the top 30. When performing sentiment analysis over these results we can see large variations after the summer of 2022 with a predominantly negative sentiment regarding this search topic.

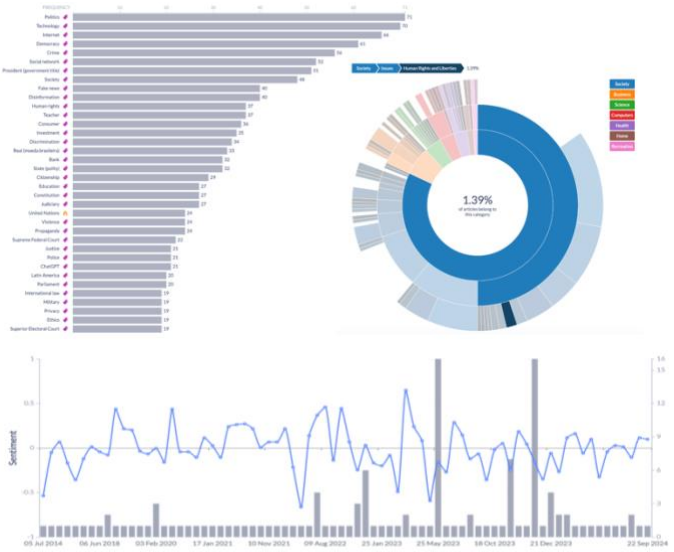

Figure 7: Significance of criminal law and AI in the news.

ACKNOWLEDGMENTS

We would like to express our sincere gratitude to the Center for Artificial Intelligence (C4AI) at the University of São Paulo (USP), supported by FAPESP and IBM, for their invaluable support to the AI Observatory team. We thank to the CIAAM for their continued collaboration and contributions to this research. We thank the support of the European Commission project ELIAS - Lighthouse of AI for Sustainability (10080425).

Povzetek

Prispevek predstavi prve rezultate ob uporabi sistema, ki je bil zasnovan in razvit v sodelovanju z OECD za spremljanje incidentov, povezanih z umetno inteligenco. Glavna motivacija teh prizadevanj je podpora zakonodaji, povezani z umetno inteligenco, in učinkovitemu oblikovanju politik, saj sistem zagotavlja vpoglede na podlagi zbranih podatkov. OECD AI Incidents Monitor za spremljanje incidentov, povezanih z umetno inteligenco, dokumentira incidente in nevarnosti v zvezi z umetno inteligenco, da bi oblikovalcem politik, strokovnjakom za umetno inteligenco in vsem zainteresiranim stranem po vsem svetu pomagal pridobiti dragocen vpogled v tveganja in škodo, ki jo povzročajo sistemi umetne inteligence. Ideja je, da bo sistem sčasoma pomagal povečati ozaveščenost javnosti in vzpostaviti skupno razumevanje incidentov in nevarnosti umetne inteligence, in tako prispeval k zaupanja vredni umetni inteligenci.

Ključne besede

umetna inteligenca, analiza podatkov, oblikovanje politik,incidenti

Abstract

This paper presents a system designed and developed in collaboration with OECD for monitoring of AI-related incidents. The main motivation behind the efforts is in supporting AI-related legislation and effective policymaking, as the system provides evidence based on the collected data. The OECD AI Incidents Monitor documents AI incidents and hazards to help policymakers, AI practitioners, and all stakeholders worldwide gain valuable insights into the risks and harms of AI systems. The idea is that over time the system will help to raise awareness and establish a collective understanding of AI incidents and hazards contributing to trustworthy AI.

Keywords

Artificial Intelligence, data analysis, policy making, AI incidents

1 Uvod

Ob vse širši uporabi umetne inteligence (UI) prihaja tudi do incidentov ob njeni uporabi. Spremljanje teh incidentov je nujno za zagotavljanje preglednosti, nadzora in razvoj politik, ki lahko takšne incidente preprečujejo ali vsaj zmanjšujejo. Predstavljeni sistem deluje kot orodje, ki pomaga uporabniku, ki si prizadeva v realnem času slediti dejanskim incidentom, povezanim z umetno inteligenco, ter zagotavljati dokazno osnovo za oblikovanje okvira poročanja o incidentih in povezanih političnih razpravah o UI. Z zbiranjem podrobnih vpogledov v vsak incident omogoča učenje iz preteklih napak ter spodbuja varnejši in bolj odgovoren razvoj ter uporabo umetne inteligence. Koristi skupnosti, ki se ukvarja z umetno inteligenco, saj izpostavlja trende in področja, ki potrebujejo pozornost ali regulativni poseg.

Prednost sistema je, da je zbiranje podatkov avtomatizirano, kar je prednost v primerjavi s podobnimi repozitoriji, ki so urednikovani ročno, kot je na primer AIAAIC Repository [2]. Repozitorij je prosto dostopen in namenjen tako oblikovalcem politik, kot razvijalcem UI, raziskovalcem, pravnikom in javnim organizacijam.

V nadaljevanju predstavimo metodologijo za spremljanje incidentov, prikažemo delovanje sistema na nekaj realnih primerih, predstavimo deležnike in nekaj zaključkov.

2 Metodologija

Metodologija OECD za spremljanje AI incidentov se osredotoča na identifikacijo in klasifikacijo incidentov, s čimer zagotavlja vpogled v realno dogajanje in podpira razvoj okvira za poročanje o incidentih. Začetna točka je identifikacija in klasifikacija incidentov, ki so poročani v uglednih mednarodnih medijih, s pomočjo modelov strojnega učenja, kar omogoča gradnjo zanesljive baze podatkov (incidenti so zajeti od 2014 naprej).

Kljub prizadevanjem, ti incidenti predstavljajo le podmnožico vseh globalnih AI incidentov. Incidenti so razvrščeni glede na resnost, industrijo, povezane AI principe (OECD AI Principles [3]), vrste škode in prizadete deležnike. Analiza temelji na naslovih, povzetkih in prvih odstavkih novinarskih člankov, pri čemer se pridobljeni podatki uporabljajo za izgradnjo zanesljive, objektivne in kakovostne baze podatkov o incidentih, povezanih z AI. Kot vir novic služi sistem Event Registry [4].

Razvoj sistema, h kateremu smo prispevali, nadgrajuje delo mednarodne skupine strokovnjakov (OECD Expert group), ki razvija teoretično ogrodje za poročanje o incidentih, definira pojem AI incidenta in oblikuje povezano terminologijo, kot je AI nevarnosti in njene potencialne posledice. Podrobna metodologija in definicije so razložene na spletni strani OECD: https://oecd.ai/en/incidents-methodology.

Slika 1 Prikaz začetne strani OECD monitorja AI incidentov (https://oecd.ai/en/incidents) prikazuje vmesnik za iskanje po konceptih, vizualizacijo incidentov v času (spodaj levo; y os: število incidentov; x os: čas (2014-danes) in statistični povzetek (spodaj

3 AI Incidents Monitor

AI Incidents Monitor je do konca avgusta 2024 zaznal preko 12 000 incidentov in nevarnosti v zvezi z UI, Kot je razvidno iz Slike 1. Sistem je popolnoma avtomatski in zaznava incidente s skeniranjem številnih podatkov objavljenih v novicah, ter nato s pomočjo UI določa kaj se označi kot incident ali nevarnost. Na naslovni strani (Slika 1) je prikazan črtni diagram naraščanja incidentov v času (levo) in pripadajoča statistika (desno). Uporabnik lahko izbira med absolutnim prikazom incidentov (kot na Sliki 1) ali v ustreznem meniju izbere pod-področja. Če se poglobimo v prikaz na Sliki 1, vidimo z različnimi barvami označeni kumulativni incidenti (vijolična) oz. njihovo trimesečno povprečje (modra). Statistika na desni prikazuje absolutno število incidentov glede na izbrano področje (12 883 incidenti in nevarnosti o katerih je poročalo 70612 novičarskih člankov), statistiko za zadnji mesec in mesece z največjimi vrednostmi (februar 2024). Iz statistik o spremembi glede na mesec, na četrtletje in na leto, vidimo padec števila incidentov in nevarnosti o katerih so mediji poročali v zadnjem mesecu glede na prejšnji mesec oz. prejšnje četrtletje.

3.1 Primer analize pojavitve incidentov UI

Sistem omogoča napredno filtriranje po incidentih UI za sledeče kategorije: čas, država, industrija, princip UI, resnost, tip škode, oškodovanci, tip iskanja po vsebini (glej Sliko 1). Tako so na primer možne vrednosti za resnost: smrt, poškodba, nevarnost, nefizična nevarnost, možni tipi škode pa so: fizična, psihološka, ekonomska, ugled, javni interes, človekove pravice, neznana.

Sistem omogoča napredno iskanje po konceptih, recimo za primer generativne UI, sistem poroča statistike, ki kažejo 2302 incidenta in nevarnosti, en od primerov incidentov, ki jih je sistem zaznal pa se nanaša na Apple in razvoj »AI personality«, ki naj bi nadomestil obstoječi Applov Siri.

Poleg konceptov uporabnik lahko nadalje izbere tudi napredno iskanje za natančnejšo identifikacijo želene podskupine incidentov, ki ga zanimajo. Tako lahko recimo izbere državo, ki je povezana s poročanjem o incidentih in nevarnostih UI. Na Sliki 2 je tako prikazan primer iskanja po kategoriji države, za Slovenijo. Sistem najde dva incidenta, ki sta bila povezana s Slovenijo. Prvi incident se nanaša na Microsoftov povečan prispevek k emisiji CO2. Na prvi pogled ni očitna povezava s Slovenijo, ko pa pogledamo povezane novice naletimo na omembo Slovenije: *»…But the tech giant's electricity consumption last year rivaled that of a small European country—beating Slovenia easily.«* [6]. Vsak primer je tudi semantično označen. Tako je na Sliki 2 za prvi primer označena povezanost s principi UI učinkovitost, trajnostni razvoj. Microsoft s tem lahko prizadene več deležnikov: splošno javnost, podjetja, delavce, vlade (Affected Stakeholders, Slika 2). Poleg tega predstavlja nevarnost za okolje, javne interese in človekove pravice (Harm type, Slika 2). Klasificirano je kot ne-fizična nevarnost (Severity, Slika 2).

Iz podrobnih analiz, ki so zbrane v nedavnem poročilu *»Observatory of the social and ethical impact of artificial intelligence«* [5], je razvidno, da večina incidentov (96%) spada pod kategorijo ne-fizično nevarnih, a imajo lahko zelo resne psihološke in finančne posledice, vključujoč nadlegovanja, odvisnosti in škodo ugledu tako posameznikom kot tudi inštitucijam.

4 Deležniki

OECD-jev monitor incidentov AI (AIM) je dragoceno orodje, zasnovano za različne deležnike, ki sodelujejo pri razvoju, regulaciji in uporabi umetne inteligence. Potencialni uporabniki tega orodja vključujejo oblikovalce politik, razvijalce AI, raziskovalce, pravne strokovnjake in javne organizacije.

Oblikovalci politik lahko AIM uporabljajo za sledenje in analizo podatkov v realnem času o incidentih, povezanih z AI, po vsem svetu, kar jim pomaga pri oblikovanju informiranih in na dokazih temelječih predpisov. Zmožnost orodja za kategorizacijo incidentov glede na resnost, industrijo in vrste škode je ključna za razumevanje širših posledic tehnologij umetne inteligence in oblikovanje politik, ki zmanjšujejo tveganja.

Razvijalci AI in raziskovalci lahko koristijo AIM, da prepoznajo pogoste težave, povezane s sistemi umetne inteligence. S preučevanjem incidentov, zabeleženih v AIM, lahko izboljšajo svoje modele, da bi se izognili podobnim težavam in povečali varnost ter zanesljivost aplikacij umetne inteligence.

Pravni strokovnjaki lahko uporabljajo AIM za pridobitev vpogledov v spreminjajočo se pokrajino tveganj, povezanih z umetno inteligenco, kar bi lahko bilo koristno v pravnih primerih ali ocenah skladnosti. Razumevanje preteklih incidentov in njihovih pravnih posledic lahko usmerja razvoj robustnih okvirov upravljanja AI.

Nazadnje lahko javne organizacije in zagovorniške skupine uporabljajo AIM za spremljanje družbenih vplivov umetne inteligence, s čimer zagotavljajo, da so interesi javnosti zaščiteni. To lahko vključuje analizo vzorcev incidentov z umetno inteligenco za zagovarjanje boljše zaščite potrošnikov in etičnih standardov pri uvajanju AI.

5 Diskusija

V prispevku smo predstavili OECD-jev monitor incidentov umetne inteligence, pri razvoju katerega smo sodelovali. Sistem služi kot dober vir za širok nabor uporabnikov, ki želijo razumeti in upravljati tveganja, povezana s tehnologijami UI. Sistem se nadgrajuje z dodatnimi podatkovnimi viri.

V prihodnosti je predvideno, da bo omogočen odprt postopek oddaje podatkov, ki bo dopolnil informacije o incidentih, pridobljene iz trenutnih virov. Nadaljnje delo zajema tudi avtomatsko analizo podatkov o incidentih za namen bolj celovitega vpogleda. To vključuje avtomatsko odkrivanja vzorcev, kot so verižne reakcije ali učinki na več industrij hkrati. Za potrebe preverjanja resničnosti poročanih incidentov, bi lahko vključili kombiniranje informacij iz več neodvisnih virov in uporabljal algoritme za odkrivanje lažnih novic, kot tudi ročno preverjanje.

Zahvala

Delo, opisano v tem prispevku, so podprli OECD in številni mednarodni eksperti, Ministrstvo za digitalno preobrazbo in Javna agencija za raziskovalno dejavnost Republike Slovenije v okviru CRP V2-2272 in V5-2264.

Acknolwedgements

The described work was supported by OECD and many os its international experts, Slovenian Ministry of Digital Transformation and Slovenian Research and Innovation Agency under CRP V2-2272 and V5-2264.

Abstract

This paper introduces the AI News Monitor system developed for real-time monitoring and analysis of artificial intelligence (AI) perception in global and local news media. Leveraging data from the Event Registry platform, the AI News Monitor tracks AI-related news articles across multiple dimensions, providing insights through three key views: a global historical overview, current global trends, and local trends specific to Slovenian media. The system facilitates both passive observation of AI discourse and active exploration of specific AI-related events. Our illustrative analysis reveals significant global trends, including heightened media focus on deep learning, generative AI, and robotics, and examines the implications of these trends on public trust in AI. Additionally, the paper discusses the practical applications of the AI News Monitor for stakeholders such as policymakers, journalists, business leaders, and researchers. We conclude with a discussion on the impact of media coverage on public perception of AI and propose possible future enhancements of the system, including broader language and source coverage.

Keywords

datasets, artificial intelligence, media monitoring, perception

1 Introduction

Artificial Intelligence (AI) is increasingly becoming an integral part of society, influencing various aspects of daily life and industries [4]. As AI continues to evolve, so does its portrayal in the media, which plays a critical role in shaping public perception and trust. Understanding how AI is perceived globally and locally is essential for policymakers, businesses, and researchers to ensure that AI technologies are developed and deployed in ways that are socially acceptable and trustworthy [3, 4].

In response to this need, we have developed the AI News Monitor system designed for real-time monitoring and exploratory analysis of AI-related news coverage. The AI News Monitor offers a comprehensive view of how AI is discussed in the media, capturing data from the Event Registry platform on a monthly basis [7].

The AI News Monitor system is structured around three main views: a global overview that presents historical data from the past year, global trends that highlight recent AI-related events, and local trends focusing on mentions of AI by Slovenian news sources. These views allow the users to either passively monitor ongoing developments in AI or actively explore specific events and trends that may influence public opinion.

Following are the main scientific contributions of this paper:
(1) We present a methodology to understand public perception about AI in news.
(2) We analyse some trends in AI's Perception.
The remainder of the paper is structured as follows. Section 2 describes the methodology to collect historical data, AI news categories and gaining insights in public perception about AI in news. Section 3 presents the analysis of trends in AI's Perception. We present different user scenarios and possible applications of AI News Monitoring in Section 4 and discussion in Section 5. Section 6 concludes the paper and outlines possible areas of future work.

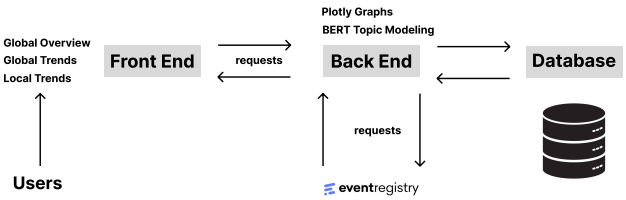

Figure 1: Architecture for Real-Time AI News Monitoring and Visualization based on Event Registry and implemented using Flask and Plotly.

2 Methodology

The proposed approach to creating a web service to analyze public perception involves two key steps: 1) identifying AI-related categories and gathering news within these categories, and 2) developing a web service that displays trends across these categories, news publishers, and highlights current trends among both global and local (Slovenian) news sources (see Figure 1).

Firstly, we selected AI-related categories based on the Slovenian AI observatory[1] and Wikipedia[2]. The key categories associated with Artificial Intelligence include 'Generative AI', 'Artificial Intelligence', 'NLP', 'Chat-GPT', 'Deep Learning', 'Robotics', 'Computer Vision', 'Neural Networks', 'Graph Neural Networks', 'Self-supervised Learning', and 'Zero-shot Learning'.

Next, we collected news articles from the last year related to these categories. These articles were classified into the appropriate categories based on Wikipedia concepts, and we also obtained sentiment data from Event Registry. The portrayal of AI-related news significantly impacts public perception, with the emphasis on risks, benefits, or ethical concerns shaping public opinion and driving narratives that can either build trust or instill fear[8],[12], [1].

To understand global trends, we retrieved news events published globally in the last month. For local trends, we focused on news

[1] http://siai.ijs.si/dashboards/Main/SlovenianObservatoryIntro?globalCountry=SVN
[2] http://country-dashboards.ijs.si/dashboards/Main/Index?

Figure 2: Time series of the number of news articles by specific areas (in colors, at the top). Detailed view upon precise exploration (middle) and corresponding sentiment of news from specific areas (at the bottom).

articles published by the top 50 Slovenian news publishers. Finally, we employed topic models to analyze the corpus of news articles and extract underlying themes [9], [2].

3 Analysis of trends of AI's Perception

3.1 Global Overview

The global overview provides a historical review of global AI-related news (see Figure 2). Users can explore the number of news articles across 13 AI fields (Generative AI, Chat-GPT, Deep Learning, Robotics, Computer Vision, Neural Networks, Graph Neural Networks, Artificial Intelligence, Federated Learning, Few-shot Learning, Meta Learning, Self-supervised Learning, and Zero-shot Learning) or by news providers and have an overview of the sentiment of the news.

Global trends allow for the review and exploration of global AI-related trends based on captured events from the last month. Figure 3 shows a detailed view of the Global Trends, where a written report of the number of news articles and events, a histogram of the number of AI-related news articles over time, and the ability to explore the last 10 events in a selected field.

3.2 Local Trends

Local trends allow for the review of news from Slovenian news providers for the last month. The local trends show the detailed view, where a written report of the number of news articles and events, a histogram of the number of AI-related news articles over time, and the ability to explore (see Figure 4).

3.3 EXAMPLES OF TRENDS

Figure 3: A detailed view of Global Trends, showing the option to select news events based on chosen AI fields.

3.3.1 Global Overview. In the historical overview of AI trends in March 2024 (Figure 2), there was a significant increase in the number of news articles and interest in deep learning, generative AI, and robotics. Specifically, on March 18th, there were 1,800 news articles about generative AI, 970 about robotics, and 274 about deep learning. This spike in news highlights several key events: one of the standout stories was the launch of Gen-2 by Runway, a generative video model capable of creating high-quality short clips. An important topic was the use of AI in political campaigns, particularly the creation of deepfakes and misinformation. This raised concerns about AI's impact on elections and voter trust. In the field of robotics, researchers were inspired by advancements in generative AI to develop more versatile robots. These new robots can perform various tasks using a single, comprehensive

model, demonstrating significant progress in robotic capabilities. Overall, the sentiment in March 2024 was positive (as seen from the sentiment analysis), reflecting enthusiasm and optimism regarding this technological progress. The increased media attention highlights the rapid development and growing importance of AI in various fields.

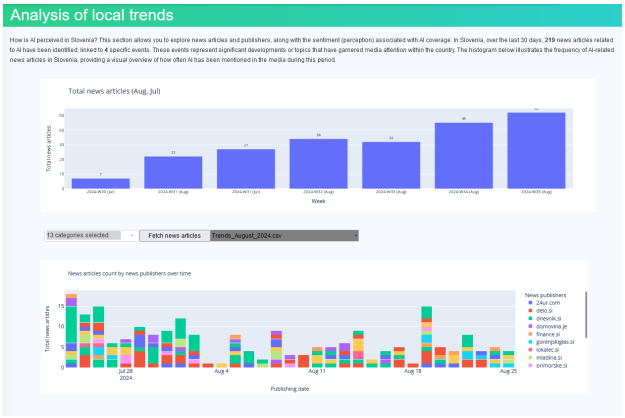

Figure 4: A detailed view of Local Trends, showing the option to select news events based on chosen AI fields.

3.3.2 Global Trends. In our examination of global trends, we selected the news story "AI and heat waves pose dual threats to the power grid" and found that two specific newspapers published more articles on this topic compared to others. The sentiment of these articles, as shown in the middle graph (Figure 4), fluctuates between positive and neutral. Upon delving into the content of these publications, we found that Forbes focused on the issue of fake news generated by AI, while Lexology explored future AI applications in various fields.

3.3.3 Local Trends. In the last month (at the time of writing the report, this was June 2024), there was an increase in AI-related news from Slovenian news providers, particularly from Delo.si and Sta.si (Figure 5). When analyzing the sentiment of these articles, most were neutral, with a few expressing positive opinions about AI. Delo.si focused on the growing adoption of AI by companies in Slovenia, highlighting discussions on the potential of quantum computing and recent advancements in AI technology. This coverage indicates a balanced view of AI's impact and potential. Sta.si reported on the construction of a state-of-the-art data center in Maribor, which will also house a supercomputer. This event represents a major development in Slovenia's technological infrastructure. Additionally, Sta.si wrote about AI trends that benefit semiconductor manufacturers, reflecting a positive outlook on the economic impact.

4 User Scenarios and Applications

The AI News Monitor can cater to a range of stakeholders with varying use case objectives [10], [6], [5]. Policy makers can utilize the developed system to track global and local trends in AI-related topics, enabling them to craft data-driven policies that balance innovation with societal concerns. Journalists can leverage the system to gather comprehensive insights into public sentiment and media coverage, enriching their reporting with accurate and timely information [11]. Detailed scenarios for both policy makers and journalists are explained below, illustrating how the AI News Monitor can support their specific goals. Other potential stakeholders are business executives, NGOs, researchers and educators.

Policy Makers: Scenario: A policymaker uses AI News Monitor to track trends in robotics.
Background: Jure, a decision-maker at a government agency for technology and innovation, is tasked with drafting new guidelines for the development and implementation of robotics in Slovenia. To understand the broader context and local trends, he needs to explore the global perception of robotics and compare it with local perspectives.
Steps: Step 1: Searching for a Global Overview: Jure logs into AI News Monitor and searches for "robotics" under the global overview section. The system displays a line chart showing how robotics has been mentioned over time, along with a sentiment graph for the past year. He finds that robotics is globally discussed with mostly positive sentiment, particularly in Asia and North America. Step 2: Global Trends: Jure selects "robotics" among the topics and reviews recent events on this subject. He chooses an event focusing on robotics in the EU and examines the sentiment of the publications and the main themes. In his browser, he looks at the specific articles and discovers that discussions predominantly revolve around automation and industrial robotics. Step 3: Local Trends in Slovenia: Next, Jure is interested in a review for Slovenia to understand how robotics is perceived at the local level. The dashboard for the selected topic displays an analysis of recent articles from Slovenian media. By using the browser, he discovers that discussions mainly focus on the impact of robotics on employment and the potential use of robots in healthcare. Jure finds that local concerns are more focused on social and economic impacts. He includes these insights in his preparatory documents for the new guidelines. Step 4: Compiling the Report and Recommendations: Finally, Jure exports key data, including sentiment graphs and media summaries, from AI News Monitor. He compiles a report that summarizes global trends and local concerns and proposes balanced guidelines that promote innovation in robotics while addressing social impacts.
Journalists: Scenario: A policymaker uses AI News Monitor to track trends in robotics.
Background: Ana, a journalist at a technology magazine, is tasked with writing an article on the growing trend of using generative AI to create videos. She needs to explore both global trends and local perspectives in Slovenia to provide a comprehensive overview.
Steps: Step 1: Searching for a Global Overview: Ana searches for "generative AI" under the global overview section. The system displays a line chart showing that this topic is on the rise, identifies the media outlets reporting on generative AI, and provides a sentiment graph for the past year. Step 2: Global Trends: Ana selects "generative AI" and reviews recent events on this topic. She focuses on deepfake video generation, checking who has written about it and what the main themes are. She then looks up these articles in her browser. Step 3: Local Trends in Slovenia: Ana shifts her focus to Slovenia to understand local views. The dashboard reveals that Slovenian media coverage is largely positive, particularly for certain providers. However, Ana realizes the need to include concerns about authenticity and misinformation to provide a balanced perspective. Step 4: Compiling and Writing: Ana exports key data, including sentiment graphs and media summaries, from AI News Monitor. She drafts her article, starting with global trends and then delving into specific concerns in Slovenia, enriched with visual data.

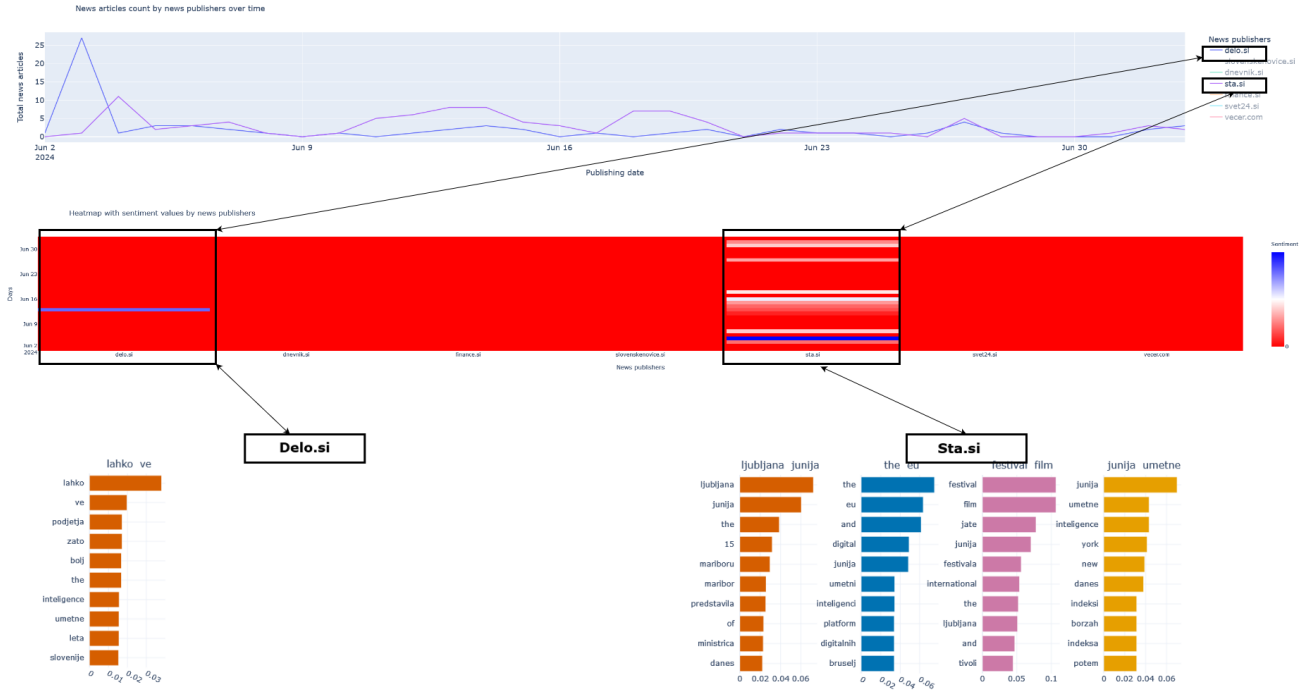

Figure 5: Time series of the number of news articles by news provider in Slovenia (at the top). Sentiment analysis (in the middle) and frequency of topics for this period (at the bottom).

5 Discussion

Services like AI News Monitor can play a role in fostering greater transparency around AI by offering detailed insights into how AI is being discussed across various media platforms. By tracking public sentiment and highlighting both positive and negative trends, it helps to ensure that the development and deployment of AI technologies are aligned with public concerns and expectations.

While AI News Monitor offers valuable insights, it has limitations, such as its reliance on media reporting, which may not capture the full spectrum of public opinion. Additionally, potential biases in media sources or the algorithms used for sentiment analysis could skew the results, presenting challenges in ensuring a fully accurate and balanced representation of public perception.

6 Conclusions

AI News Monitor was developed to understand and track public sentiment around AI, offering policymakers, journalists, and other stakeholders the insights needed to make informed decisions. AI perceptions can be monitored globally and locally, for the context of Slovenia. However, there are opportunities for future work to enhance its capabilities. Expanding the its coverage to include more languages and diverse sources would provide a more global perspective, while refining sentiment analysis techniques could improve accuracy and reduce potential biases.

ABSTRACT

Strategic foresight helps organizations anticipate future challenges and opportunities, allowing them to handle uncertainty better. While strategic foresight is becoming more widely adopted across organizations, the process still heavily relies on expert knowledge, and little of it has been automated through artificial intelligence. In this research, we explore how media news events can be analyzed to forecast event types that will take place in the near future. In particular, we consider it a supervised machine learning problem with a well-defined set of event types and leverage graph representation of the media news events to create graph embeddings, train a classifier, and predict event types that will likely occur one day ahead. We validated our approach on a real-world dataset of an American multinational conglomerate operating in industry, worker safety, healthcare, and consumer goods.

KEYWORDS

strategic foresight, event prediction, machine learning, graphs

1 INTRODUCTION

Strategic foresight helps organizations anticipate future challenges and opportunities, allowing them to handle uncertainty better [9]. Therefore, predicting future event types as a part of strategic foresight became necessary for businesses to manage their operations without significant losses. Various events on a major scale, such as floods, earthquakes, internet failures, or pandemics, as we are witnessing recently, or on a minor scale, such as road closures due to sports events or promotions at fairs, can have a major impact on business operations. By predicting the next event type, businesses can adjust prices, reschedule staff, manage stocks, reschedule transportation routes to avoid delays, and more, and thus reduce losses or increase their sales and profits.

There is currently a massive number of articles written on Future Event Predictions. Based on Zhao [11], the event prediction methods can be classified in terms of goals into time prediction, location prediction, semantics prediction, and a combination of these. Each goal is divided into subgoals for which various techniques can be applied. According to the classification provided by Zhao, our technique can be classified as a semantic prediction.

In this research, we explore how graphs can be used to model media news events and to forecast event types in the near future. By doing so, we provide a valuable tool for decision-makers, offering them a clearer view of potential outcomes. Specifically, our research focuses on using a JSON dataset containing a variety of articles about a particular business company. We create a graph representation of the articles and use Graph2Vec to create embeddings that can be used downstream to fit other machine-learning models. Using this information, we apply a Random Forest Classifier to predict the categories of articles about the company for the following day.

In particular, we expect this to be useful to give organizations a competitive advantage in fast-changing markets [5]. While human expertise is valuable, it varies from person to person, leading to inconsistent predictions. Manually analyzing large datasets is also time-consuming and prone to errors. AI, however, can process vast amounts of data, spot patterns, and predict future event types more accurately.

This work is structured as follows. Section 2 presents related work that is relevant for this paper. Section 3 describes the data in the dataset, and the data extraction process. Section 4 introduces a new approach to predict future event types. Section 5 presents the results of this research. Section 6 concludes this work and proposes future improvements.

2 RELATED WORK

In recent decades there has been an increasing interest in strategic foresight in the academic field. According to Fergnani (2020) [2] this is because by "using corporate foresight, organisations can reconfigure their strategy based on the analysis of business opportunities suggested by future possibilities". Even in academia "one of the domains heavily impacted by Artificial Intelligence is innovation management and in this context especially the area of Strategic Foresight (SF)" as per Brandtner et. al (2021) [1].

However it seems that strategic foresight methods related to AI only end up being used by bigger companies with a larger number of resources. As noted by Kim and Seo (2023) [6], "except for AI start-ups and players in the consumer electronics and information and communication industry, small- and medium-sized enterprises (hereafter SMEs) in other industries do not demonstrate competence in AI." Therefore, effective implementation of AI solutions for strategic foresight in smaller and medium sized

companies would be one of the topics to be explored in future research.

In this research however, we focus more on the general implementation of strategic foresight by means of next event prediction. Exploring similar fields, we found that there was already some research exploring the field of event predictions, which rather than focusing on businesses focused on other domains. In the field of sequential event prediction, several researchers are exploring diverse methods. Although the methods share some conceptual similarities with our research, they differ significantly in methodology and focus. Letham, Rudin, and Madigan (2013) [7] developed a model that predicts the next event using an ERM-based approach with logistic regression, focusing on the presence of events rather than their order. On the other hand, our work uses labeled article databases and considers the sequence of past events, using techniques like graph construction, random walks, and random forests. Yeon, Kim, and Jang (2015) [10] focus on predicting event flow through visual analytics, using LDA for topic extraction and emphasizing specific keywords, while our approach is entirely text-based and relies on graphs. On the other hand, Hu et al. (2017) [4] use LSTM networks for predicting future subevents, which offers an alternative method to our non-LSTM-based text analysis.

Although these studies provide useful insights and have offered significant improvement in sequential event prediction, they may face certain challenges. For instance, Letham, Rudin, and Madigan (2013) [7] emphasize event presence over sequence, potentially missing key temporal relationships, while Yeon, Kim, and Jang (2015) [10] depend heavily on keywords, overlooking broader context. Additionally, LSTM-based models like those used by Hu et al. (2017) [4] are powerful however they require significant computational power. In contrast, our work addresses these limitations by employing a graph-based approach that prioritizes event sequences and leverages standardized data from sources like DMOZ and Wikipedia. This enables us to make more accurate and efficient predictions, offering a practical and scalable solution that enhances predictive accuracy.

3 DATASET

3.1 Data Extraction Pipeline

The event detection pipeline processes about 300.000 English news articles per day. Each news article is first annotated using tools like entity linking, topic classification and sentiment detection. Each article is then split into sentences where each sentence retains it's annotations and other meta-data. For each pair of the entities in the sentence, an event classifier then determines if there is a particular relation of interest expressed in the sentence between the two entities. The predefined taxonomy currently includes 133 event types of interest, ranging from security, environment, natural disasters, accidents, politics, and other areas. To classify the events, a neural network transformer architecture with a pretrained encoder is used. The entire network, including the encoder, is trained on our supervised dataset using best practices like online hard example mining, class balancing, dropout, and consistency regularization. The sentences for which the classifier finds that it mentions a relation of interest are then stored in a database, together with the pair of associated entities and other available meta-data.

data = {"uri": ["2024-07-423118842-0"], "date": ["2024-07-16"], ..., "eventType": ["et/business/equity-actions/fundraising"], ..., "slots": ["http://en.wikipedia.org/wiki/Czech_Republic"]}

Figure 1: Sample of relevant data considered when parsing an event type to build the dataset.

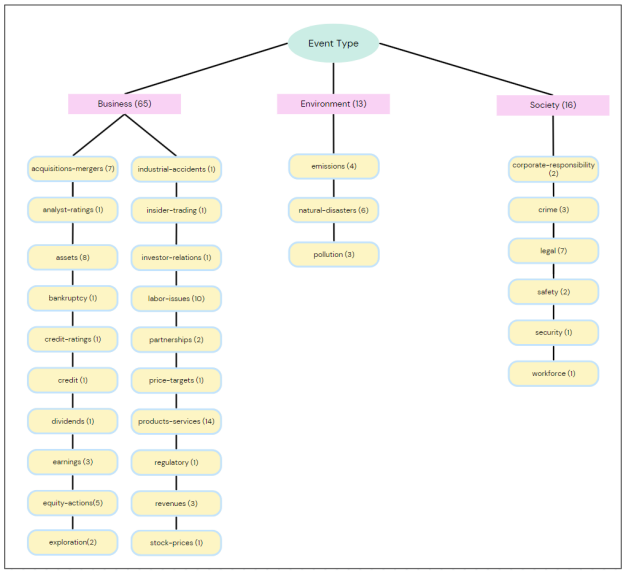

Figure 2: Event Type Taxonomy

3.2 Data Description

For our research, we used a dataset of events provided by Event Registry, with media events encoded in JSON format. Specifically, we analyzed 4,216 events related to the company 3M, recorded between June 23, 2021, and July 23, 2024. We used a URI to classify each event, drawing from DMOZ and Wikipedia categories (Fig. 1). These were selected because they provide standardized descriptions of the events being reported, which makes the data consistent and reliable. The events are categorized into 94 distinct types, which are further grouped into three primary domains: business, environment, and society. The business domain makes up the largest proportion of events, accounting for 65 types (69% of the total), while the environment and society domains contain 13 types (14%) and 16 types (16%), respectively. Within these domains, the event types are further divided into smaller subdomains, which can be aggregated into larger subdomain units as demonstrated in the event type taxonomy (Fig. 2).

4 METHODOLOGY

This study uses graph-based techniques to predict future event types from news articles about a specific company. The process starts by building a graph that maps relationships between event types and concepts from Wikipedia and DMOZ. Random walks are then performed on this graph to extract key information such as URIs, dates, and event types, which are then transformed into embeddings using Graph2Vec [8]. Next, the event types are encoded and adjusted through a process called target shifting. This step aligns the features to better forecast future outcomes based on previous data. The predictions are made using a Random Forest classifier, which is then validated through stratified k-fold

a) b) c)

Figure 3: Event Type Graphs

cross-validation for higher accuracy. The following sections will present each step of this process in more detail (see Fig. 4).

4.1 Graph Construction

For each article in the JSON dataset, a detailed graph G is generated using the NetworkX library [3]. The graph construction process starts by extracting key information such as the article's URI(unique identifier), as well as the date associated with the article and the event types, which are represented by specific URIs. In addition to these elements, each article also includes two important lists: 'slots' and 'categories'. The 'slots' list contains wiki and dmoz addresses that are directly related to the event described in the article, while the 'categories' list includes various classifications of the event. To complete the graph, labels are created by extracting URIs from the 'slots' list and filtering the 'categories' to focus on those with the "dmoz" prefix.

4.2 Random Walks for Feature Extraction

Once the graphs for each article are constructed, random walks are performed, starting at a given node (event type) and moving to adjacent nodes based on specific probabilities. Several random walks are generated for each node, forming the foundation for feature extraction processes. A single random walk begins by initializing the path with the starting node and iterating over a specified path length. At each step, a random number is compared with a probability p. If the number is less than p, the walker stays at the current node, otherwise it moves to a random neighbor. If no neighbors are available, the walk ends.

Generating multiple random walks for every node follows a similar approach, using p as the probability of staying at the current node (set at 0.05). The process involves creating an empty list to store all random walks and iterating through each node in the graph. For each node, the specified number of random walks is generated, and each walk is appended to the list.

4.3 Embedding Generation Using Graph2Vec

The random walks from the graphs are processed similarly to word sequences in a document. The 'embedding_data' function generates vector embeddings for graph data using the Doc2Vec model. It begins by converting each random walk into a TaggedDocument, storing these in 'documents_gensim'. The Doc2Vec model, with a vector size of 5 is trained on these documents, creating a vector space where similar sequences are positioned close together.

The function then processes each graph in the graphs dictionary, extracting uri, date, and event type, and generating additional random walks. These walks are converted into embeddings using the 'infer_vector' method, and the resulting vectors are averaged into one final embedding. This embedding is stored in a dictionary across 'embedding1' to 'embedding5', alongside the graph's metadata.

4.4 One Hot Encoding & Target Shifting

To transform the categorical event types into binary vectors, One hot encoding is applied. This allows the model to treat each event type as a separate class. After extracting relevant column names, the encoded target data is concatenated with the feature embeddings, creating a dataset for model training and evaluation. The dataset is then aggregated by averaging out the embeddings and calculating the maximum value of the encoded target columns for a given day. Finally the 'target' data is shifted by one day, which allows the embeddings to forecast the event types for the following day.

4.5 Random Forest Classification & Stratified K-Fold Cross Validation

To ensure an effective classification and prediction of the data, A Random Forest classifier is created. When employing this method, embeddings are used as features and the one-hot encoded event types are used as labels. The data itself is split into testing and training sets, followed by the incorporation of the Stratified K-Fold cross validation. This technique splits the data into 10 folds, while ensuring that the event type proportion in each fold remains equal. The model is then trained on 9 folds, with the remaining fold being used for validation. This ensures balanced representation of each class across the folds resulting in a more effective performance.

5 RESULTS

As mentioned above, the model was trained on a training set, and then evaluated on a test set. The training set included approximately 508 samples for each fold, and the test set included about 10% of the whole set, which amounted to 56 samples per fold. Using this, the model then predicted the probabilities for event types for each set. When training the model for each class, we noticed certain classes did not have enough occurrences to have at least one entry of such a class per dataset fold and were skipped. We, therefore, trained the model and predicted for a total of 45 classes.

To evaluate the discriminative performance of the model, the ROC AUC score was used. The results produced showed us how well the model distinguishes between different classes, as well as the model's ability to predict future event types. The ROC AUC score showed us that the average performance of the model was around 0.5674, and the median was close to it, with an AUC ROC score of 0.5559, with the highest score reaching 0.8194 and the lowest reaching a value of 0.3338. While the best scores demonstrate we can effectively forecast event types ahead of time, further work is required to enhance results, which in most cases remain close to 0.5.

6 CONCLUSIONS

This study was used to develop a graph-based approach to predicting event types in articles. In the process, we utilized random walks for feature extraction and Doc2Vec for embedding generation. Then, we trained the resulting model on a Random Forest classifier and evaluated it with a Stratified K-Fold Cross Validation. The model demonstrated solid performance with an average ROC AUC score of around 0.5674, reaching a peak at approximately 0.8194. This indicates the model's effectiveness in capturing relationships within the data and predicting future event types.

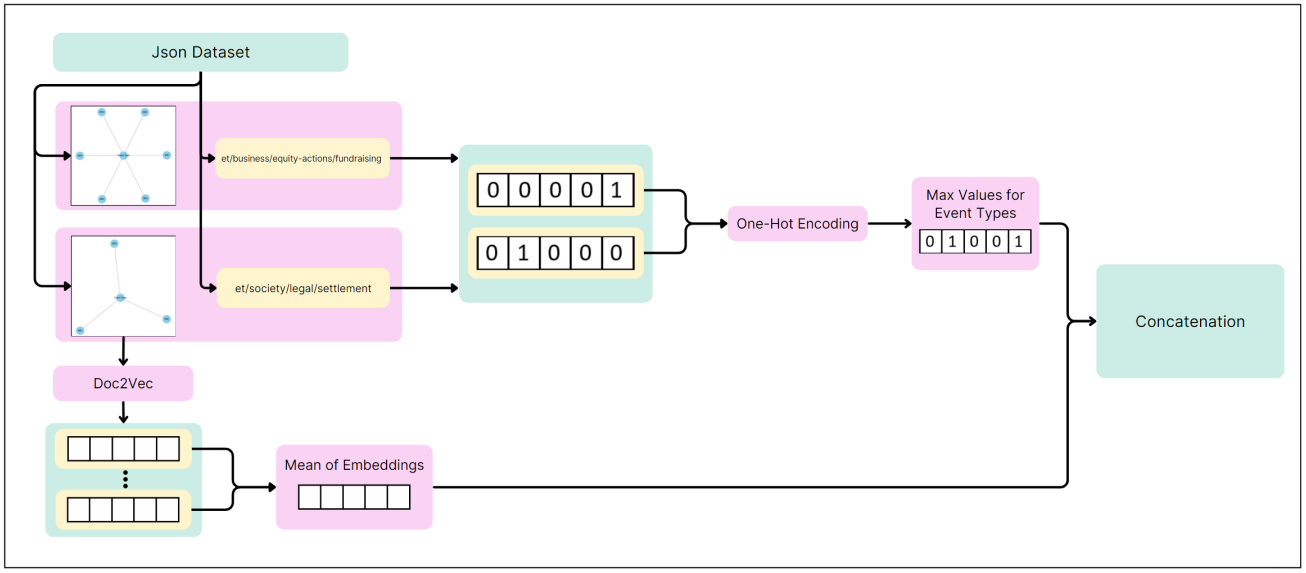

Figure 4: Data Extraction Pipeline

However, while the model performed well overall, occasional fluctuations in accuracy suggest space for further improvement. We are currently striving to find ways to make graphs more informative. In future work we could refine the feature extraction process by incorporating larger datasets, with a wider variety samples and a larger number of companies.

Abstract

Using synthetic datasets to train medicine-focused machine learning models has been shown to enhance their performance, however, most research focuses on English texts. In this paper, we explore generating non-English synthetic medical texts. We propose a methodology for generating medical synthetic data, showcasing it by generating Greeklish medical texts relating to hypertension. We evaluate our approach with seven different language models and assess the quality of the datasets by training a classifier to distinguish between original and synthetic examples. We find that the `Llama-3` performs best for our task.

Keywords

Synthetic data, healthcare data, multilingual data, large language models, classification

1 Introduction

The healthcare domain produces a lot of medical data that can be used to train machine-learning models to help medical personnel. For example, a machine-learning model designed to perform Named Entity Recognition (NER) on electronic health records (EHRs) needs extensive labeled datasets to accurately identify medical terms like diseases, treatments, and patient details. However, the data contains a lot of personal information, and hospitals cannot share it freely due to data protection. In addition, there are not enough examples to train the models for some problems, such as those relating to rare diseases. Because of this, synthetic data is being used as a substitute to train the models.

Most synthetic data generation approaches focus on generating English texts. These usually utilize large language models trained on predominantly English documents retrieved from the web. However, there are few examples of using them to generate non-English texts. Furthermore, the language models have difficulties generating texts that do not reflect the distributions found in the training sample. This includes medical texts, which are usually not accessible to the general public.

This paper proposes a methodology for generating medical synthetic data using open-source large language models. We apply the methodology to a medical data set written in Greeklish, a combination of Greek and English scripts. We test it with seven large language models and assess performance by training a classifier to distinguish original examples from synthetic ones. Using the same prompt, we find that the open-source Llama-3 model best generates synthetic data that reflects the original data set.

The remainder of the paper is as follows: Section 2 presents the related work on generating synthetic data using large language models. Next, the proposed methodology is described in Section 3. The experiment setting is presented in Section 4, followed by the experiment results in Section 5. We discuss the results in Section 6 and conclude the paper in Section 7.

2 Related Work

This section describes the related work, focusing on large language models and methods for generating synthetic data.

2.1 Large language models

Large Language Models (LLMs) are models that were trained to generate human-like texts based on an extensive process of training on vast amounts of data. Models, such as Llama 3 [2], GPT-4 [9], Aya 23 [3] and Mistral [7], are often easy to work with by providing an input textual prompt, based on which the models respond. The LLMs are helpful in specialized fields, such as medicine, since they can be fine-tuned on extensive data sets containing medical terms and concepts. This enables them to perform well in tasks such as medical synthetic data generation [12]. Despite that, they are sometimes unable to follow the instructions in the prompt accurately, leading them to hallucinate, i.e. confidently produce wrong responses [5].

In our experiments, we investigate the LLMs' performance in generating synthetic medical data given specific constraints and detailed prompts to simulate the original data set as best as possible.

2.2 Synthetic medical data generation

Recently, synthetic medical data, generated using LLMs, has been used to enhance the performance of models for solving different natural language processing tasks in medicine.

One work focuses on generating a synthetic dataset of electronic health records of Alzheimer's Disease (AD) patients based on a label that is provided [8]. They find that the performance of their system for detecting AD-related signs and symptoms from EHRs improves vastly when trained on synthetic and original data sets as opposed to training the system only on the original one. Another work investigated using LLMs for extracting structured information from unstructured healthcare text [13]. By generating synthetic data using LLMs and fine-tuning the model, they significantly improved the models' performance for medical-named entity extraction and relation extraction tasks.

Most related works focus on English synthetic data due to scarce non-English training data and the dominance of English in medical terminology [6]. This paper focuses on generating non-English texts, specifically medical texts written in Greeklish about hypertension.

3 Methodology

This section outlines our research methodology. We first present the pre-processing of the data set, followed by describing the synthetic data generation process. Finally, we present the description of synthetic dataset evaluation using a classifier. Figure 1 shows the diagram overviewing the proposed methodology.

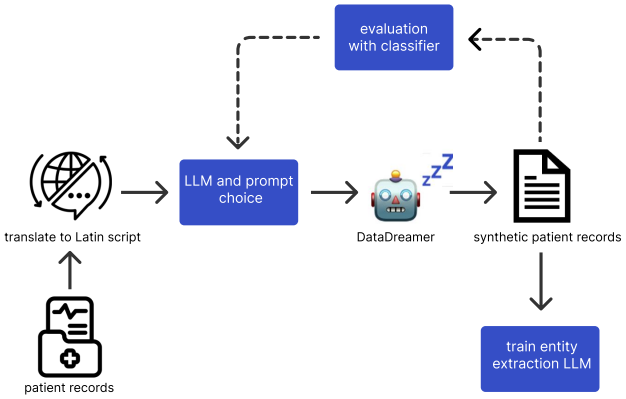

Figure 1: An overview of the methodology. The image was designed using resources from flaticon.

3.1 Data pre-processing

The data set used consisted of 1,299 examples of medical history in Greeklish, where the Latin and Greek scripts were used interchangeably. It also contained 1,495 labels, most of which were in English. The labels consisted of drugs, medical events, and measurements.

To translate the labels into Greek, we used the `NLLB-200` [14] translation model[1]. Since LLMs were predominantly trained on texts written in Latin script, we decided to transliterate both the labels and examples from Greek to Latin script. This allowed the LLMs to generate longer tokens with richer information.

We split the original data set into two subsets to ensure no data leakage. The first one, consisting of 930 examples, was used for synthetic data generation. The second one, containing the remaining 369 examples, was used for evaluation.

3.2 Synthetic data generation

We utilized the datadreamer library [10] to generate the synthetic data set. The library enables open-source models to create synthetic data sets and was developed to work in research settings, supporting prompt templates and few-shot learning.

We developed a prompt containing the instructions and restrictions on generating the examples. To better showcase the structure of the generated text, we also provided five random examples from the original data set as few-shot examples. Next, using datadreamer, we sent the prompt to the chosen LLM. We experimented with multiple LLMs, and about 800 examples were generated for each used LLM. When experimenting with LLMs that required calling an external provider (e.g., OpenAI), we provided five static few-shot examples that did not include any patient personal data due to data privacy concerns.

To ensure the quality of generated data, we implemented a post-processing step. This included formatting the generated text into one line and excluding examples where the length was too long or where the model started repeating words meaninglessly. This ensured that all generated examples followed the same format and could be used for evaluation.

Table 2 presents generated examples for the label "OSTEOPOROSH". Similarities in the examples highlight the need for rigorous methods to evaluate how closely they resemble the original data set. The methods are explained in Section 4.1.

[1]https://huggingface.co/facebook/nllb-200-distilled-600M

3.3 Technical details

In this section, we describe the models and the parameters used in the experiment. All models used are available via the HuggingFace's transformer library [15].

We tested five open-source models to generate the synthetic data sets, all of which can be run on a 32GB GPU: `Llama-3` [2] only has support for the English language but has been fine-tuned to understand user prompts, which is a feature we expected would help a lot with the synthetic data generation.[2] `Aya-23` [3] is a multilingual language model and offers support for 23 languages, including Greek.[3] `Mistral` [7] supports a variety of languages but omits Greek[4]. The models `Gemma-2` [4] and `Phi-3` [1] were also tested and compared in the experiments.[5][6] In addition, we experimented with `GPT-4o` [9] and `GPT-3.5-Turbo`, which are accessible via the OpenAI API.

All models were given the same prompt containing instructions that included (1) generating Greek texts written in Latin script and (2) containing a label randomly selected from the original data set, (3) examples are supposed to be at most 6 words long, (4) should provide concise responses, (5) structured format (all text must be in a single line, must use // and commas as separators, and must be similar in format as the provided few-shot examples). To stress some more important instructions, some instructions were given in capital letters and were also repeated.

4 Experiment Setting

This section describes the experiment setting, which consists of the evaluation process and the metrics used to measure the approach's performance.

4.1 Evaluation approach

The quality of the generated synthetic data was measured in two parts. The first consisted of statistical measurements, such as calculating the average length of the generated examples and finding the proportion of examples that included the required labels. These statistics were then compared to the original data set.

The second part consisted of training a classifier to discern if the input text was from the original or from the synthetic data set. The data set used to train and evaluate the classifier involved 369 randomly selected synthetic examples and 369 examples from the original data set, transliterated into Latin script. We chose 5-fold validation as our classification procedure and calculated the mean performance across all trials.

The classifier was trained using the BERT [11] language model, specifically the `bert-base-multilingual-cased` variant[7]. The classifier was trained using the following parameters: batch size = 16, epochs = 3, and learning rate = 2e-5. The same parameters were used for all synthetic data sets.

4.2 Metrics

To assess the quality of the generated synthetic data sets, we used the F1 score as our main metric for evaluating the classifier's performance. The target value was 0.5; if the performance is greater than 0.5, the classifier can discern the original from the synthetic examples. Hence, the synthetic data does not reflect the original data set. If the performance is less than 0.5, the

[2]https://huggingface.co/meta-llama/Meta-Llama-3-8B-Instruct
[3]https://huggingface.co/CohereForAI/aya-23-8B
[4]https://huggingface.co/mistralai/Mistral-7B-Instruct-v0.3
[5]https://huggingface.co/google/gemma-2-9b-it
[6]https://huggingface.co/microsoft/Phi-3-medium-4k-instruct
[7]https://huggingface.co/google-bert/bert-base-multilingual-cased

classifier has difficulties separating the synthetic from the original data, which can be because the synthetic data contains copies of the original examples. In addition to the F1 score, we measured the classifier's accuracy, precision, and recall, which are also reported.

5 Results

In this section, we present the results of our experiment. We first present the statistical results, followed by the classifier's evaluation.

5.1 Statistical analysis

Table 1 compares the synthetic data sets and the original one regarding label occurrence and average example length. The label occurrence is 1.000 in the original data set, as all examples from the original data set are assumed to include relevant labels and information.

The most aligned synthetic data set regarding label occurrence was generated using `GPT-4o`, followed by `Llama-3`. However, in terms of average example length, the data set generated using `Gemma-2` performed the best, followed by `Llama-3`.

The worst-performing models, in terms of label occurrence, were `Mistral` and `Phi-3`, which in about 25% did not include the selected label. The data set generated using the `Aya-23` had the largest difference in terms of average example length, on average generating examples with three extra words.

Table 1: Statistical comparison between the original and synthetic data sets. The bold and underlined values represent the best and second-best statistics, respectively.

LLM	Label occurrence	Avg example length
original dataset	1.000	4.682
`Llama-3`	<u>0.990</u>	<u>5.330</u> (+0.648)
`Aya-23`	0.949	8.040 (+3.358)
`Mistral`	0.740	6.376 (+1.694)
`Gemma-2`	0.988	**4.207** (-0.475)
`Phi-3`	0.782	6.071 (+1.389)
`GPT-4o`	**0.996**	3.691 (-0.991)
`GPT-3.5-Turbo`	0.867	6.764 (+2.082)

Looking at both statistics, we can conclude that `Llama-3` had the best alignment to the original data set in terms of label occurrence and example length, closely followed by `GPT-4o`.

To better imagine the differences between the generated examples, we handpicked an example from each synthetic data set related to the label "OSTEOPOROSH", shown in Table 2.

5.2 The classifier evaluation

Table 3 shows the F1, Precision, Recall, and Accuracy performances of the trained classifier on different synthetic data sets. The best performance was achieved by `Mistral` with approximately 0.85 scores in all four metrics, followed by `Llama-3`, with approximately 0.88 scores in all metrics. The worst performances were on data sets generated by the `Aya-23` and `GPT-3.5-Turbo` models. Surprisingly, the `Aya-23` is a language model supporting Greek; thus, it was expected to generate better examples.

6 Discussion

This section discusses the synthetic data generation performance, outlines our methodology's limitations and drawbacks, and proposes potential improvements to the approach.

6.1 LLM performance

Results in Table 1 show significant quality differences among synthetic datasets from different LLMs, with label occurrence ranging from 0.740 for `Mistral` to 0.996 for `GPT-4o`, and average example length from 3.691 for `GPT-4o` to 8.040 for `Aya-23`.

However, Table 3 indicates no significant performance differences within a single synthetic dataset, with a maximal standard deviation of the metrics being 0.021 for the `Llama-3` dataset.

We can also notice that the F1 and accuracy scores are very close for all synthetic data sets. This means the classifier was likely performing relatively similarly on both classes (synthetic and original datasets) without significant bias to either class.

We can observe much better performance on the `Llama-3` data set, which is primarily trained on English data, than on the `Aya-23` data set, which is also trained on Greek data. This shows that a model does not need to be extensively trained in Greek texts to generate this type of synthetic medical data well.

6.2 Limitations

Due to limited computing power, only one GPU with 32GB of space was available, restricting the testing of larger LLMs. To address these challenges, using cloud-based resources or distributed computing could help run larger models and improve the variety of synthetic data generated.

Due to privacy concerns, when using `GPT-4o` and `GPT-3.5-Turbo` models, which are not locally-run models, we had to use five fixed examples when generating synthetic data instead of a larger variety. This potentially led to larger similarities of the `GPT` synthetic datasets to the examples instead of the original dataset and, consequently, worse performance.

6.3 Potential improvements

The prompt was the same for all seven LLMs and was primarily tested on `Llama-3`. Hence, the performance might be biased towards the model. The method could be improved by tailoring the prompts to each model individually.

The evaluation of synthetic datasets could be further extended by checking for repeating examples in the synthetic dataset or by checking how different the generated example is from the five provided examples. The evaluation could also be improved by checking for overfitting to the original data set.

7 Conclusion and Future Work

This paper presents a method for generating Greek synthetic medical data sets. To synthetically create datasets similar to the original, we carefully craft a prompt and perform pre-processing and post-processing of the data to increase performance and eliminate the effect of hallucinations.

Using a classifier and considering the inclusion of labels and generated text length, we conclude that `Llama-3` is best for generating examples that most closely resemble the original dataset. In the future, we plan to explore the underlying architectures of the models to understand their performance differences in multilingual contexts. This will allow us to further refine our methods and create more accurate data sets.

Furthermore, we intend to use the synthetic dataset to train a named entity recognition (NER) system to recognize medical labels from medical history examples. Measuring the performance of the NER trained on synthetic datasets will give us another way of evaluating their quality. We also intend to create a more general pipeline enabling the code to generate synthetic medical data in a wider variety of languages and formats.

Table 2: Generated examples for label "OSTEOPOROSH".

LLM	Examples
original dataset	APO 2O ETON YPERTASH ME AGOGI// OSTEOPOROSH // YPOTHYROIDISMOS
Llama-3	YPOTHYROEIDISMOS, OSTEOPOROSH, APO//
Aya-23	CA ORTHOU, ANEYRISMA KOILAKHS AORTHOU, OSTEOPOROSH.
Mistral	OSTEOPOROSH, APO 60 ETOS, APO 2 MHNES KAI APO 10 GRAMM
Gemma-2	OSTEOPOROSH, ARTHROSITIS, ETOVIR
Phi-3	OSTEOPOROSH, XAROSTHROMA, ALPHA-BISFIOVITINI, 2018, DIATHRHSH, DIA
gpt-4o	OSTEOPOROSH, ANEMIA
gpt-3.5-Turbo	OSTEOPOROSH, GASTREKTOMH, EMFISIMA, YDRONERFOSI, PSIXROS.

Table 3: Mean performance metrics of the classifier for synthetic data sets, with standard deviation. Performances that are closer to 0.5 are considered better. The bold and underlined values represent the best and second-best performances, respectively.

LLM	F1	Precision	Recall	Accuracy
Llama-3	<u>0.875 ± 0.021</u>	<u>0.881 ± 0.020</u>	<u>0.875 ± 0.020</u>	<u>0.875 ± 0.020</u>
Aya-23	0.945 ± 0.005	0.947 ± 0.004	0.945 ± 0.005	0.945 ± 0.005
Mistral	**0.848 ± 0.012**	**0.856 ± 0.001**	**0.849 ± 0.011**	**0.849 ± 0.011**
Gemma-2	0.928 ± 0.005	0.930 ± 0.005	0.928 ± 0.005	0.928 ± 0.005
Phi-3	0.927 ± 0.009	0.932 ± 0.008	0.927 ± 0.009	0.927 ± 0.009
GPT-4o	0.906 ± 0.014	0.912 ± 0.012	0.907 ± 0.014	0.907 ± 0.014
GPT-3.5-Turbo	0.940 ± 0.013	0.944 ± 0.011	0.940 ± 0.013	0.940 ± 0.013

Abstract

The rise of digital media enhances information accessibility but also introduces challenges related to the quality and impartiality of news reporting, particularly regarding biases that influence public perception during key global events. In response, this study introduces *LLNewsBias*, a dataset designed to detect and analyze political bias in multilingual news headlines, covering four major events from 2019 to 2022 — Brexit, COVID-19, the 2020 U.S. election, and the Ukraine-Russia war. With over 350,000 headlines in 17 languages, annotated with bias labels, this dataset is compiled using Media Bias/Fact Check and Event Registry. Our contributions include a structured framework for data collection and organization, enabling event-wise and year-wise analysis while supporting lifelong learning. We also highlight potential use cases that demonstrate the dataset's utility in advancing bias prediction models, multilingual adaptation, and model robustness. Additionally, we discuss the dataset's limitations, addressing potential biases, sample size constraints, and contextual factors. This work provides a valuable resource for improving bias detection in dynamic, multilingual news environments, contributing to the development of more accurate and adaptable models in natural language processing and media studies. For code and additional insights, visit: https://github.com/Swati17293/LLNewsBias

Dataset, News, Bias, Multilingual, Headline, Low-resource, Media Bias, News Bias, Continual Learning, Lifelong Learning

1 Introduction

The rapid growth of digital media has greatly enhanced the accessibility of information, but it has also introduced significant challenges concerning the quality and impartiality of news reporting. Political bias in news content is particularly concerning, as it has the potential to influence public perception and shape societal narratives, especially around key global events. Understanding and predicting such biases, particularly in multilingual contexts where biases can manifest differently across cultural and linguistic boundaries, is essential for promoting fair and balanced journalism. Traditional approaches to bias detection often rely on monolingual datasets and static models that may not effectively capture the evolving nature of news content [6]. These limitations underscore the need for more robust datasets and methodologies that can adapt to the dynamic and multilingual landscape of modern news reporting.

https://doi.org/10.70314/is.2024.sikdd.8

In this study, we address these challenges by introducing a novel dataset *LLNewsBias* specifically designed for the detection and analysis of political bias in multilingual news headlines. Our dataset spans four major global events from 2019 to 2022: Brexit, COVID-19, the 2020 U.S. election, and the Ukraine-Russia war, capturing a wide range of political discourse across 17 languages. To collect this dataset, we use Media Bias/Fact Check for the assignment of bias labels, and Event Registry [2] for the extraction of relevant headlines and metadata. The resulting dataset is not only comprehensive in its linguistic diversity but also structured to support both event-wise and year-wise analyses, with an emphasis on lifelong learning.

1.1 Contributions

Our study makes the following contributions:

- **Multilingual bias-annotated dataset:** We introduce a multilingual bias-annotated dataset containing over 350,000 news headlines in 17 languages, each annotated with political bias labels.
- **Data collection and organization framework:** We present a structured framework for data collection and organization, enabling event-wise and year-wise analysis while ensuring adaptability for lifelong learning.
- **Potential use-cases:** We outline several potential applications of our dataset, highlight its potential for advancing lifelong learning models, particularly in bias prediction, multilingual adaptation, and model robustness.
- **Discussion of limitations:** We identify and discuss the dataset's limitations, such as biases in data collection, sample size constraints, and contextual influences, offering a transparent assessment of its applicability.

In summary, our paper introduces a comprehensive dataset and a framework for the study of political bias in multilingual news headlines. By focusing on key global events and providing support for lifelong learning, our study contributes to the ongoing effort to develop more accurate and adaptable models for bias detection in diverse linguistic and cultural contexts.

2 Related Work

Several datasets focus on news articles and political bias [5], but there is a notable scarcity of multilingual, bias-annotated datasets designed for lifelong learning [4]. While resources like the *media bias chart* by Ad Fontes Media and PolitiFact provide insights into bias, they are often limited to English-language sources or specific fact-checked claims, lacking the continuous, event-centric data necessary for broader analysis. GDELT [3], a large-scale event-oriented news dataset, covers multiple languages but focuses on location, network, and temporal attributes rather than political bias or the event-outlet relationship. Existing multilingual datasets are often domain-specific [1], limiting

their utility for general bias analysis. In contrast, LLNewsBias dataset fills these gaps by offering a generalized, multilingual, and bias-annotated data designed for event-wise and year-wise analyses, particularly suited for lifelong learning models.

3 Dataset Description

In this section, we introduce our dataset *LLNewsBias* and describe the framework used for its collection and organization. We begin by detailing the primary data sources that form the foundation of this dataset. Following this, we present a comprehensive overview of the data collection process, with a focus on the methodologies employed to ensure robustness and reliability. Finally, we provide an in-depth overview of the dataset's structure, including its directory organization, file contents, and the various ordering methods applied to facilitate detailed analysis. Our dataset is documented in accordance with the FAIR Data Principles.

3.1 Primary Data Sources

In this section, we outline the two primary data sources used in our study: Media Bias/Fact Check (MBFC) and Event Registry (ER). MBFC serves as the bias rating portal, providing bias labels for selected media outlets, while ER is used to extract the headlines and corresponding metadata from articles published by these outlets.

3.1.1 ***Media Bias/Fact Check.*** For bias labeling in this study, we utilized Media Bias/Fact Check (MBFC), a well-established platform known for its comprehensive coverage and frequent updates. Although other platforms like allsides.com and adfontes-media.com also provide bias ratings, MBFC was selected for its reliability and particular focus on low-resource languages. MBFC assigns bias labels based on political orientation and evaluates outlets for credibility and factual accuracy. These labels are determined by a team of contractors and volunteers who follow a standardized methodology, ensuring that the ratings are both consistent and dependable for our analysis.

3.1.2 ***Event Registry.*** In this study, we use Event Registry [2] platform as the primary source for collecting multilingual news headlines. It aggregates content from over 150,000 news sources across more than 60 languages, making it an ideal resource for analyzing bias in diverse and low-resource languages. Apart from the headlines, it allows access to numerous metadata such as publication date, news category, and political bias. By leveraging its Python API, we efficiently filtered and extracted headlines relevant to our study. This ensured a comprehensive dataset that supports the analysis of bias in a lifelong learning setup, exploring how emerging events and domain shifts influence the performance of bias prediction models over time.

3.2 Data Collection Framework

Our data collection framework as depicted in Figure 1, is designed to support both event-wise and year-wise analyses, with the additional capability of facilitating lifelong learning.

For data collection, we begin by defining two sets: a set of significant global events ($E = \{e_1, e_2, ..., e_n\}$), and a set of years ($Y = \{y_1, y_2, ..., y_m\}$), where n and m represent the total number of events and years, respectively. We then use the Media Bias/Fact Check (MBFC) platform to select media outlets ($O = \{o_1, o_2, ..., o_p\}$) and determine their respective political bias, with p as the total number of outlets. To maintain data reliability, we exclude outlets labeled as questionable and assign each remaining outlet $o_i \in O$ a bias label $b_i \in B$, where $B = \{b_1, b_2, ..., b_q\}$ represents the set of bias labels, with q representing the number of distinct bias labels.

Next, we define a temporal query Q_t to extract article headlines ($H = \{h_1, h_2, ..., h_r\}$), where r represents the total number of headlines retrieved from the Event Registry (ER). The query Q_t is formulated as:

$$Q_t = \{Q_e, Q_o, Q_{cat}, Q_{dt}\} \tag{1}$$

where Q_e, Q_o, Q_{cat} specify the event, media outlet, and news categories (limited to those classified as 'news' by ER $Q_{cat} = \{$'*politics*', '*business*', '*sports*', '*arts and entertainment*', '*science*', '*technology*', '*health*', '*environment*'$\}$), respectively. The time constraint is represented as $Q_{dt} = [Q_{sd}, Q_{ed}]$, where Q_{sd} and Q_{ed} denote the start and end dates. To scrape all the article headlines (H), we utilize Q_t to query ER.

We then associate the extracted headlines H with the corresponding bias labels in B and structure the dataset according to two classification types: event-wise and year-wise. To organize the data, we define an event-based order O_{event} and a year-based order O_{year} as follows:

$$O_{event} = \{e_1 \rightarrow e_2 \rightarrow ... \rightarrow e_n\} \tag{2}$$

$$O_{year} = \{y_1 \rightarrow y_2 \rightarrow ... \rightarrow y_m\} \tag{3}$$

For lifelong learning, we design the dataset to be extendable, allowing for the integration of new events and years as they emerge, denoted by $E' \subseteq E$ and $Y' \subseteq Y$, where E' and Y' represent the sets of newly added events and years.

We designed the dataset with a flexible framework that allows for the seamless integration of new events and years as they emerge, represented as $E' \subseteq E$ and $Y' \subseteq Y$, where E' and Y' denote the newly added events and years. This structured approach ensures scalability for continuous learning without requiring major restructuring and supports the training of adaptive models capable of integrating new information effectively. Unlike standard multi-year datasets, our dataset includes annotations that facilitate contextual understanding, enabling models to learn from historical data while adapting to evolving trends and patterns in news reporting. This ensures that the models remain relevant as new information becomes available.

Finally, we split the dataset into training and test sets using a stratified sampling approach to ensure the preservation of bias label distributions across both events and years. We perform this step as it is critical for maintaining the integrity of the model training process in a lifelong learning context.

3.3 Data Synopsis and Structure

In this section, we present an overview of the data and explain how it is systematically organized, making it easier to understand both the content and format of our dataset.

3.3.1 ***Data Synopsis.*** The dataset features 356,060 headlines on four major events from 2019 to 2022: *Brexit*, *COVID-19*, *the election*, and *the Ukraine-Russia war*. These headlines, sourced from 45 unique news outlets in 17 different languages, are annotated with 3 political bias labels: *Left Centre*, *Least Biased*, and *Right Centre* covering diverse topics such as *politics*, *business*, *arts and entertainment*, *sports*, *science*, *technology*, *health*, and *environment*. The dataset is structured into 7 distinct columns within .csv files. Table 1 presents a comprehensive summary of the dataset statistics.

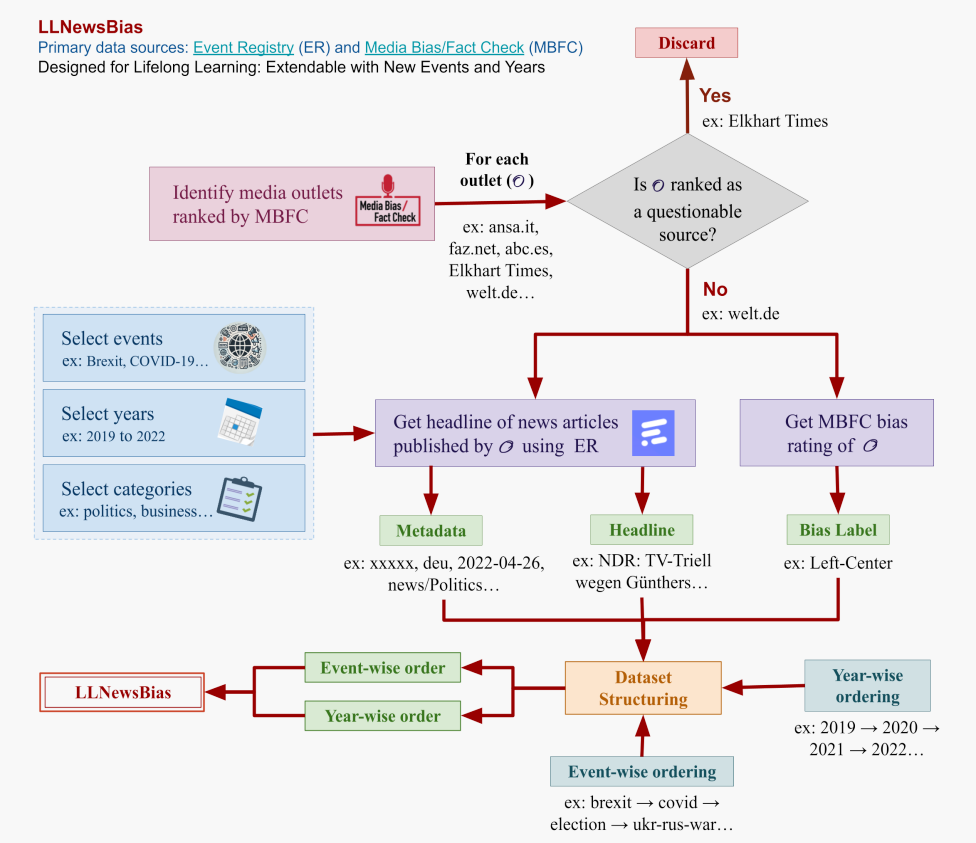

Figure 1: Data Collection Framework. The framework uses MBFC for bias labeling and ER for headline retrieval.

Table 1: Summary of Dataset Statistics.

Language-wise Distribution			
Catalan	882	Romanian	17,038
Croatian	13,929	Russian	10,511
Czech	1,876	Slovak	5,642
Danish	4,330	Spanish	83,940
Dutch	10,905	Swedish	6,441
Finnish	1,512	Ukrainian	10,616
French	85,007	Italian	48,450
Hungarian	105		
Event-wise Distribution			
Brexit	32,286	COVID	309,329
Election	3,829	Ukraine	10,616
Year-wise Distribution			
2019	20,664	2021	4,638
2020	258,871	2022	71,887

3.3.2 ***Directory Structure.*** The dataset is organized in a main 'data' directory with subdirectories categorized by events ('brexit', 'covid', 'election', 'ukr-rus-war') and years (2019-2022). Additional subdirectories consolidate data across all events (ordered_events) and all years (ordered_years). Each subdirectory contains .csv files for training and testing, structured across the following columns.

- **news outlet**: The name of the news outlet.
- **article_ID**: A unique identifier for the raw news article in the Event Registry platform from which the headlines are extracted.
- **language**: The source language of the published news article.
- **date**: The date on which the news was published.
- **headline_text**: The text of the news headline.
- **news_category**: The category assigned by Event Registry.
- **political_bias**: The political bias of the news outlet as provided by the bias rating portal Media Bias/Fact Check.

The dataset is annotated with bias labels: Left Centre (LC), Least Biased (LB), and Right Centre (RC). To ensure model robustness across varying data distributions, we concatenate and shuffle files for each event and year in four distinct random orders. This prevents overfitting to specific sequences and helps evaluate generalization across diverse configurations. While chronological order is ideal for practical use, this randomized approach tests broader performance, with the original event and year splits provided for user flexibility.

Event-wise Ordering:

(1) brexit → covid → election → ukr-rus-war
(2) election → covid → ukr-rus-war → brexit
(3) brexit → ukr-rus-war → election → covid
(4) covid → brexit → ukr-rus-war → election

Year-wise Ordering:

(1) 2019 → 2020 → 2021 → 2022
(2) 2021 → 2020 → 2022 → 2019
(3) 2019 → 2022 → 2021 → 2020

(4) 2020 → 2019 → 2022 → 2021

The dataset captures the distribution of headlines related to various events over the years, reflecting the temporal dynamics of news coverage and the evolving reporting on these events. The differences in coverage levels reveal important patterns in media attention, which are essential for developing datasets that support lifelong learning models.

4 Potential Use-Cases

Our dataset introduced in this study has a wide range of potential use-cases, particularly in the fields of natural language processing and media studies. It is particularly valuable for research and applications that require understanding and predicting news bias in a continual, multilingual environment. Below we list some potential use cases:

- **Lifelong learning for news bias prediction:** Our dataset is ideal for developing and testing lifelong learning models. It allows models to adapt to new events and evolving entities. With its year-wise structure from 2019 to 2022, the dataset addresses the challenges of emerging events and domain shifts (e.g., Brexit, COVID-19, Ukraine-Russia War), providing the data needed to develop and evaluate robust models.

- **Domain Adaptation in Multilingual Contexts:** Our dataset enables researchers to investigate domain adaptation techniques in a multilingual context, featuring headlines in 17 languages. This facilitates the development of models that generalize across languages and adapt to various cultural and political contexts, ensuring accurate bias prediction. It addresses the challenges faced by generic models in the news domain, which often struggle with topic and language diversity.

- **Sparse Experience Replay for Continual Learning:** Our dataset is particularly well-suited for the news domain, supporting efficient experience replay by allowing the selection of specific topics and categories. With its event-wise and year-wise classifications, our dataset enhances memory utilization, improves generalization, reduces catastrophic forgetting, and ensures that models remain accurate and up-to-date in real-time applications.

In a nutshell, our dataset serves as a valuable resource for advancing news bias prediction, particularly in the context of lifelong learning, by providing a flexible framework for integrating new events and years. Unlike many news-based datasets with timestamps, it offers structured annotations and contextual information that enhance the understanding of evolving trends in news coverage, making it particularly suitable for lifelong learning applications. It supports a range of research activities, from model development and evaluation to the exploration of new techniques for handling dynamic and multilingual news environments.

5 Limitations

Several limitations are associated with the dataset presented in this article and should be carefully considered in any further research or analysis:

- **Data Collection Issues:** The dataset was gathered using Media Bias Fact/Check (MBFC) and the paid version of Event Registry (ER). MBFC is publicly accessible, while ER provided comprehensive but limited coverage, potentially missing relevant articles. The use of ER's paid version also restricted the extent of data collection.
- **Sample Size:** The dataset is constrained by its focus on four major events over a span of four years. This limited number of events and time frame may not fully capture the broader spectrum of news and media biases, affecting the diversity of the samples.
- **Biases:** Selection bias is a significant factor, as only news outlets labelled by MediaBiasFactCheck were included. This restriction may limit the number of languages and perspectives represented in the dataset, thereby influencing the overall analysis.
- **Contextual Factors:** The dataset is limited by its temporal scope, covering only four specific events over four years. While it reflects the dynamic nature of news media, it does not account for all future events and years to come.

6 Conclusions

In this study, we present LLNewsBias, a comprehensive dataset designed to tackle the challenges of detecting and analyzing political bias in multilingual news headlines. By spanning four major global events from 2019 to 2022 across 17 languages, this dataset provides a valuable resource for research in natural language processing and media studies. Our framework supports both event-wise and year-wise analysis, emphasizing lifelong learning and enabling models to adapt continuously to new data. The dataset's potential use cases include enhancing bias prediction models, facilitating domain adaptation in multilingual contexts, and improving model robustness. While LLNewsBias offers significant contributions, we also acknowledge limitations such as potential biases in data collection, sample size constraints, and contextual factors. Addressing these challenges in future work will be crucial for maximizing the dataset's impact, ultimately contributing to fairer and more balanced journalism.

Abstract

A key limitation of state-of-the-art large language models is their lack of a consistent world model, which hinders their ability to perform unseen multi-hop reasoning tasks. This paper addresses this by extracting local world models from text into a systematic first-order logic framework, enabling structured reasoning. Focusing on the educational domain, we present a multi-step approach using Prolog to represent and reason with these models. Our method involves segmenting educational texts, generating Prolog definitions, and merging them into a comprehensive knowledge graph. We successfully extracted several small models and manually verified their accuracy, demonstrating the potential of this approach. While promising, our results are currently limited to small-scale models.

Keywords

Large language models, local world models, knowledge representation, educational technology, structured reasoning, knowledge graphs

1 Introduction

In recent years, Large Language Models (LLMs) have revolutionized the field of Natural Language Processing (NLP), offering unprecedented capabilities in understanding, reasoning over, and generating human-like text. Despite their impressive performance across various language tasks, a significant limitation persists – the absence of a consistent and coherent world model within these systems [8]. This limitation hampers their ability to perform advanced reasoning tasks that require not only textual understanding but also logical consistency and structured knowledge representation.

While current LLMs are powerful, they are inherently constrained by their reliance on statistical correlations within vast datasets, often resulting in shallow and contextually inconsistent reasoning. To address this limitation, we propose an approach for extracting local world models, i.e., small, context-specific representations of knowledge that capture the relationships and rules governing a particular domain or scenario. The approach is multi-step. First, the input text is segmented into manageable parts. Each segment is analyzed to extract key concepts and their interrelationships, which are then represented as Prolog definitions. Then, the definitions are merged into a comprehensive knowledge graph that reflects the structure and content of the input text.

We focus specifically on the educational domain, where the ability to generate and utilize local world models could significantly enhance the effectiveness of AI-driven educational tools, e.g. by providing LLMs a framework for responding with logically consistent and pedagogically sound explanations. Moreover, by modifying some of the components, the approach can also be applied to other domains, such as industry, finance, and law.

The remainder of the paper is as follows: Section 2 presents the related work on LLMs and creating world models. Next, the proposed approach is described in Section 3. The experiment setting is presented in Section 4, followed by the experiment results in Section 5. We discuss the results in Section 6 and conclude the paper in Section 7.

2 Related Work

The recent surge in large language models, such as GPT-3 [3] and GPT-4 [1], has significantly advanced natural language processing, showing emergent reasoning abilities across various tasks. However, despite their impressive performance, LLMs are often criticized for lacking factual consistency, interpretability, and logical coherence, especially in complex, multi-hop reasoning tasks [8]. To address these shortcomings, efforts have been made to integrate LLMs with structured knowledge frameworks, like knowledge graphs (KGs) and ontologies, to enhance reasoning and knowledge flow between structured data and language models [9].

In the field of ontology and KG development, early initiatives like Cyc [6] laid the groundwork for large-scale structured knowledge representation. More recent efforts [8, 5] have explored using LLMs to assist in ontology generation and KG construction. While LLMs can automate parts of the ontology development process, they struggle with ensuring logical consistency and managing complex domain-specific knowledge [5, 2]. Complementary approaches, like using LLMs for ontology learning [2] and structured knowledge extraction [10], highlight the need for human validation and formal methods to ensure accuracy.

Our work builds on these insights by focusing on using LLMs to extract structured local world models in the form of Prolog-based representations. This approach addresses the limitations of LLMs in handling complex reasoning and provides a more robust, logically consistent framework for educational applications.

3 Methodology

This section introduces the approach for creating local world models by generating and utilizing structured data in Prolog. The methodology is designed to systematically identify and map the concepts and their interrelationships within a given educational document, such as a textbook, facilitating the generation of a knowledge graph.

3.1 Document segmentation

To manage the document's complexity and ensure accurate concept extraction, the source material was divided into several shorter parts, each up to 10 pages long. This segmentation was crucial in allowing us to focus on smaller, more manageable sections of the content, enabling a thorough analysis and avoiding problems that come with long-context LLM outputs. The length of each part was determined based on the natural divisions within

https://doi.org/10.70314/is.2024.sikdd.22

the text, such as chapters or major sections, to maintain the coherence of concepts within each segment.

3.2 Generating Prolog definitions

For each segmented part, we created a prompt to generate Prolog definitions of the concepts and their relationships. The prompt was carefully crafted to guide the extraction of educational content in a structured format. It consisted of three main components: the context, the predicates and the structured output.

Context. A description of the educational context and a brief narrative to position the content within a learning scenario. This helped to align the LLM-extracted concepts and relationships with our downstream tasks. The following is an example of the prompt used:

> *You are a teacher and an expert in natural language processing (NLP). You wrote a chapter in an NLP textbook and would like to convert the content of the chapter into a classroom lesson. You would like to step into the shoes of a student in order to understand their learning process of this material. You need to understand which concepts are being taught and their relationships.*

Predicates. List of predicates and their descriptions, which were essential for identifying concepts (`isConcept(A)`), prerequisites (`isPrerequisiteOf(A, B)`), and sections (`isSection(S)`). These predicates were used to simulate the learning process, where concepts are linked to sections. A concept may have prerequisite concepts or sections that must be understood before a student can advance to learning the concept.

Structured output. Clear instructions to output the extracted predicates in the form of a Prolog program. The LLM responding in a structured format a crucial part of our approach, as it has been shown that structured responses can improve LLM reasoning and generation quality [13].

In summary, this prompt allowed us to extract detailed summaries of the concepts taught and their relationships, which were then represented in Prolog. Each segment was processed independently to generate a corresponding Prolog program.

3.3 Merging Prolog definitions

After generating the Prolog definitions for each segment, the next step was to merge them into a single cohesive program. To achieve this, we created a prompt, which was nearly identical to the first, but with instructions to combine the disjoint parts into one integrated Prolog program added to the end of the prompt:

> *Now you need to combine the parts into a single Prolog program. Make sure to include all the concepts and relationships, but also properly connect them. Merge concepts from different sections where necessary and make sure to include all the sections and their relationships.*

3.4 Use of the knowledge graph

The generated knowledge graph, represented by the Prolog program, was then used to recommend the next steps in the learning process. Using the structured output, we created a detailed concept map that helped identify key learning paths and prerequisites. Prolog (specifically SWI Prolog [11]) was chosen for this task because it can handle structured data, is widely used (increasing the likelihood that LLMs have encountered it during training), and can be executed and analyzed immediately.

4 Experiment Setting

This section outlines the experiment setting for evaluating our approach to extracting local world models from educational texts and generating structured Prolog representations. We describe the data sources, the large language model used, and the evaluation framework.

4.1 Data sources

We evaluated our approach on two widely used textbooks in deep learning and natural language processing. These texts were chosen because they are relevant to both structured reasoning tasks and the representation of complex, multi-step concepts. The following chapters were selected for analysis:

Deep Learning Preliminaries from the book *Dive into Deep Learning* [12]. This chapter provides foundational knowledge of deep learning, covering key concepts such as linear algebra, calculus, and probability, which are essential for understanding the field. The textbook's teaching approach is highly hands-on, with a significant portion devoted to code. It is open-sourced, and we used the Markdown files provided on their GitHub page[1].

Chapter 2: Regular Expressions, Tokenization, and Edit Distance from *Speech and Language Processing* [4]. This chapter introduces basic NLP techniques, focusing on regular expressions and tokenization, which are pivotal in text preprocessing tasks.

4.2 Used large language model

We employed GPT-4o via the ChatGPT interface to extract concepts and their interrelationships. We leveraged the model's multimodal capabilities, allowing it to process text and PDF documents.

4.3 Evaluation Framework

We developed an evaluation framework to assess the performance of our approach based on three primary aspects: accuracy, completeness, and consistency. To validate the results, we manually reviewed the extracted knowledge graphs and compared them with the source texts. We ensured that the extracted concepts were accurate, complete, and logically consistent.

Assessment Criteria. The following criteria were used to evaluate the effectiveness of our approach:

- *Accuracy.* This aspect examines how accurately the approach extracted the concepts and their relationships from the text. We evaluated the correctness of each Prolog definition against the source material.
- *Completeness.* This evaluates whether the system captured all the key concepts from the educational material. The assessment ensured that no significant concepts or relationships were omitted during extraction.
- *Consistency.* This aspect assesses the extent to which the extracted models maintained logical coherence across different

[1] https://github.com/d2l-ai/d2l-en

segments of the text. This was crucial in determining whether the segmented Prolog definitions could be merged into a cohesive KG.

5 Results

In this section, we review the knowledge graphs of the two tested texts generated by our model.

5.1 *Dive into Deep Learning*

The selected chapter covered six sub-chapters in the following order: Data Manipulation, Data Preprocessing, Linear Algebra, Calculus, Automatic Differentiation, and Probability and Statistics. The results are represented by the graph in Figure 1.

The system accurately identified three major independent branches of the chapter – Linear Algebra, Calculus, and Probability and Statistics – which reflects the structure of the source material. The extracted knowledge graph also logically restructured the content in ways that differed from the original organization but made sense pedagogically. This restructuring highlights the logical flow of how data handling techniques naturally feed into more abstract mathematical concepts despite differing from the original structure.

However, some omissions and reassignments were noted, particularly within the Linear Algebra section. Concepts such as vectors and matrices were omitted, likely due to the high-level nature of the extraction process. Additionally, matrix multiplication, though identified, was separated from Linear Algebra basics and Tensor operations. This disjunction represents a slight deviation from the expected conceptual hierarchy.

Similarly, in the Calculus section, the extracted model restructured the sequence of topics. This restructuring captured the relationship between fundamental calculus concepts and their practical applications in machine learning. Furthermore, the system included concepts like Gradient Descent and Backpropagation which were only briefly mentioned in the source material.

5.2 *Speech and Language Processing*

The Regular Expressions section, seen in Figure 2, was extracted accurately, capturing the core concepts effectively. However, a noticeable limitation was the loss of the original sequencing of the concepts presented in the textbook. While the key ideas were identified, the pedagogical flow, which is essential for gradual learning, was somewhat disrupted in the extraction process.

For the other sections, including Tokenization and Edit Distance, the model extracted only the most prominent concepts, omitting many important details. As a result, these sections are less comprehensive than they need to be for in-depth understanding. Despite this, the overall connections between sections in the knowledge graph were logically structured, showing that the system was still able to create a coherent representation of the material at a high level.

It is important to note that this textbook is significantly more information-dense and longer compared to the *Dive into Deep Learning* book. This added complexity exposed some limitations in the current approach, mainly when dealing with texts that require detailed extraction of concepts and their interrelationships. The model's ability to handle such dense material is limited by its tendency to focus on top-level ideas while losing much of the depth and sequencing provided in the source text. Additionally, there were rare occasions where the output required manual interventions to fix inconsistent formatting of the Prolog variable names.

6 Discussion

Our approach to extracting local world models from educational texts demonstrated strong performance in generating logically coherent knowledge graphs from high-level concepts, but certain limitations were identified. The synthetic data generation effectively captured core concepts from both textbooks, particularly in structuring major branches such as Linear Algebra, Calculus, and Probability from *Dive into Deep Learning*. However, some restructured sections, while logical, differed significantly from the source material's flow.

In the *Speech and Language Processing* textbook, the Regular Expressions subsection was extracted with sufficient accuracy. Other sections, such as Tokenization and Edit Distance, suffered from detail omissions, where only top-level concepts were extracted. This issue was more prominent due to the higher information density of the NLP textbook, exposing limitations in handling detailed, densely packed content.

Regarding the evaluation framework, the model generally performed well on metrics like accuracy and consistency but struggled with completeness in more detailed sections. The model's tendency to restructure content logically, though sometimes deviating from the original, suggests that while it captures core relationships, further refinements are needed to preserve pedagogical flow and details.

6.1 Potential improvements

To address the limitations, improving the prompt engineering could lead to more detailed extractions while maintaining the structure of the source material. Additionally, enhancing the model's ability to handle complex, dense information would mitigate the loss of key concepts. Future iterations may benefit from automated post-processing checks to ensure logical consistency and reduce manual interventions. Overall, while the approach shows promise, refining it to handle finer details and complex sequences more effectively will be essential for broader applications.

7 Conclusion and Future work

In this paper, we proposed a novel approach to extracting local world models from educational texts by generating structured Prolog representations. Our methodology demonstrated the ability to capture core concepts and their interrelationships in a logical and coherent manner, especially in the *Dive into Deep Learning* textbook. However, the results from the more information-dense *Speech and Language Processing* text revealed limitations, particularly in handling detailed content, large knowledge graphs, as well as preserving pedagogical flow.

The use of Prolog proved effective in organizing educational material, allowing for structured reasoning and enabling applications in AI-driven educational tools. Despite these successes, certain challenges remain, such as the omission of detailed concepts and the system's occasional tendency to deviate from the original sequence of topics.

Future work will address these limitations by improving the prompt engineering and enhancing the system's ability to handle complex, information-dense material. Additionally, we plan to explore automating the segmentation process and scaling up the

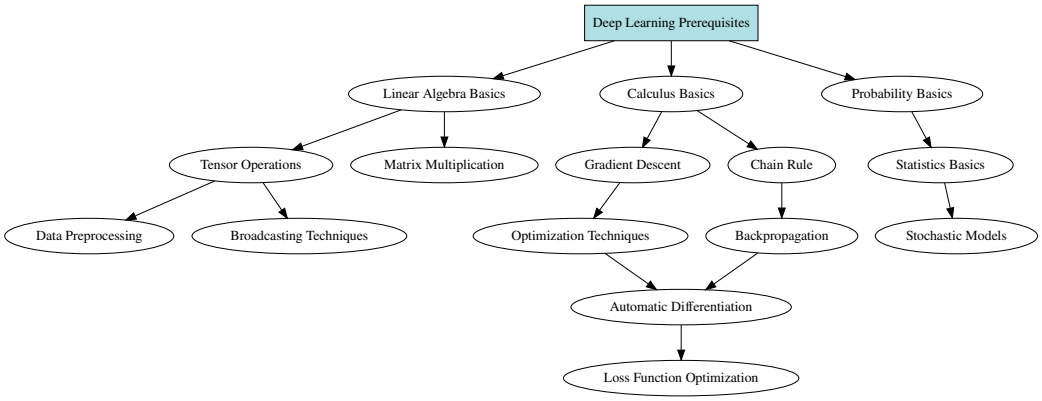

Figure 1: Knowledge graph of the *Preliminaries* section from *Dive into Deep Learning*.

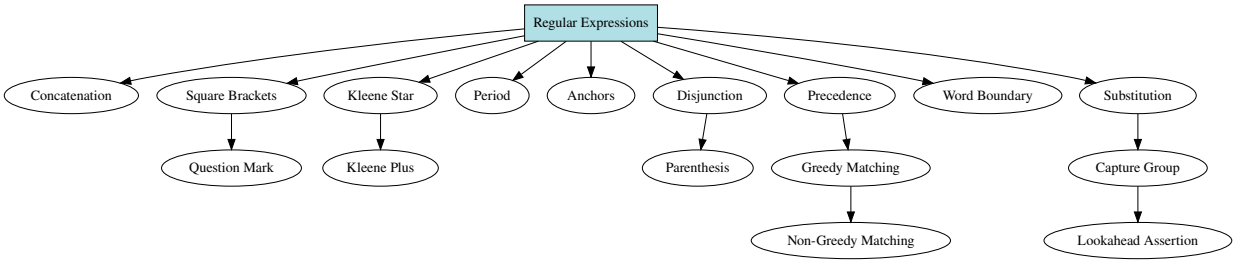

Figure 2: Knowledge graph of the *Regular Expressions* section from *Speech and Language Processing*.

model to generate larger, more intricate knowledge graphs. Other potential directions include integrating retrieval-augmented generation [7] to enrich knowledge extraction and comparing generated world models across different texts to evaluate their pedagogical alignment. Self-evaluation and correction mechanisms could also be introduced to improve accuracy and completeness.

Abstract

The rapid growth of video streaming platforms has intensified the demand for personalized content recommendations. However, current solutions often rely on historical user data, leading to challenges like the cold start problem and overlooking users' immediate preferences. We present a conversational recommendation system that leverages large language models (LLMs) to generate keyword-based content and query descriptions. By integrating Retrieval-Augmented Generation (RAG), our system efficiently retrieves relevant content, independent of prior user interactions, and ensures consistent performance across languages. Preliminary testing shows our system outperforms the RAG baseline by up to 24% in less descriptive queries and demonstrates consistent performance across three languages. While the results are promising, further evaluation focusing on user interaction and satisfaction is necessary. Our approach can potentially be extended to other recommendation systems, offering broader applicability and enhanced content personalization.

Keywords

large language models, recommendation system, search system, retrieval augmented generation

1 Introduction

The surge in video streaming platforms has accelerated the demand for personalized content recommendations. As these platforms expand their libraries and user bases, the challenge of delivering precise, user-specific recommendations intensifies. In this dynamic environment, streaming services must quickly adapt to provide accurate recommendations, which are crucial for maintaining user engagement and ensuring satisfaction.

Existing recommendation systems primarily rely on historical user interaction data, such as viewing history and ratings. This dependence leads to significant challenges, such as the cold start problem, where new users or newly added content lack sufficient data for accurate recommendations. Additionally, these systems often fail to account for users' immediate preferences, which can change dynamically due to various factors such as mood, viewing context (e.g., watching alone or with a group), or recent events in the user's life. This gap highlights the need for more adaptive and responsive recommendation mechanisms.

Recent advancements in Large Language Models (LLMs) present an opportunity to address these limitations. LLMs offer significant potential due to their emergent reasoning abilities, their capacity to extract high-quality representations of textual features, and their ability to leverage the vast external knowledge encoded within them [10], [7]. By harnessing LLMs, it is possible to create a recommendation system that interacts with users to capture their immediate preferences, thereby overcoming the cold start problem and enhancing the relevance of recommendations. Additionally, ensuring consistency in the quality of recommendations across different languages is increasingly important as many streaming services operate globally.

Our approach utilizes LLMs to generate keyword descriptions for both content and user queries. These keywords serve as the basis for recommendations, with a Retrieval-Augmented Generation (RAG) [6] model efficiently retrieving relevant content. By crafting query keywords using LLMs, the system adapts to user preferences in real time, providing relevant and language-consistent recommendations.

This paper makes the following contributions: **(1) Development of a Keyword-Based Recommendation System:** We introduce a novel approach that utilizes LLMs to generate keyword-based descriptions for content and user queries, enabling more personalized and adaptive recommendations. **(2) Exploration of Two User Interaction Models:** We propose and evaluate two distinct interfaces for user interaction—a conversational chat-based model and a structured question-answering model, where the system refines recommendations through a series of targeted yes/no questions generated by the LLM. **(3) Comprehensive Evaluation Strategy:** We outline a detailed plan for evaluating the system's performance in a production environment, focusing on its ability to deliver consistent, high-quality recommendations across different languages and user contexts.

2 Related Work

Recommender systems have progressed from techniques such as collaborative filtering and matrix factorization to more complex models that incorporate deep learning. The advent of large language models (LLMs) has enabled innovative methods for interacting with these systems [11], particularly when combined with retrieval techniques [9]. One of the most promising advancements in this area is the use of Retrieval-Augmented Generation (RAG) models, which integrate the powerful text generation capabilities of LLMs with retrieval-based methods to improve recommendation accuracy and relevance [6].

Recent advancements in conversational recommender systems have focused primarily on integrating LLMs with traditional recommender systems or fine-tuning LLMs using user-item interaction data [9], [10], e.g., [8], [4], and [5]. These approaches, while effective, often rely heavily on historical user data, leading to challenges such as the cold start problem. This reliance underscores the need for novel methods that reduce dependency on past interactions and leverage real-time retrieval mechanisms to enhance content recommendations [2].

To address these challenges, recent work by Di Palma et al. (2023) [2] introduced a Retrieval-Augmented Recommender System, which combines the strengths of LLMs and retrieval-based methods. Their approach employs LLMs both at the conversational layer and the backend retrieval process, thereby improving recommendation relevance, particularly in scenarios with sparse data or new users. Their experimental results demonstrated that

https://doi.org/10.70314/is.2024.sikdd.10

this RAG-based framework performs comparably to state-of-the-art systems, even in zero-shot scenarios, underscoring the potential of such an approach to mitigate cold start and hallucination problems inherent in LLMs.

Our approach builds on the strengths of RAG-based models by introducing a keyword-based recommendation system that operates within a RAG framework. This system ensures consistent performance across multiple languages and adapts to real-time user preferences without relying on historical user data.

3 Data

The data used in this study was provided by our partner United Cloud, who operate a multinational streaming service in the Balkan region, EON TV[1]. The EON platform encompasses a variety of content, such as video-on-demand (VOD) movies and TV shows, as well as live TV channels. We focused exclusively on VOD movie data, although our approach is capable of accommodating multiple content types.

The VOD movies data set comprises nearly 5000 movies in various languages. Each movie is accompanied by a brief description averaging around 460 characters (5-6 sentences) in multiple languages. In cases where multiple translations were available, we opted for the original language of the movie; otherwise, we chose the first available translation.

4 Methodology

4.1 Recommendation Mechanism

The core of our recommendation system is the generation of textual representations of content. Instead of using movie descriptions directly, we employ the LLM to generate a set of English keywords and related movies. This approach prevents the model from overemphasizing less relevant details, such as specific plot points, that may not be central to the user's query. User queries follow a similar approach, where the LLM generates a set of relevant keywords, as well as any possibly relevant movies.

One of the key advantages of this method is its ability to abstract core concepts from user queries using the LLM, aligning better with the keywords generated from movie descriptions. The LLM-generated keywords from both the movie descriptions and user queries are designed to encapsulate the essential topics and themes. By aligning the keywords generated from movie descriptions with those derived from user queries, our system enhances the relevance of the recommendations. This alignment is crucial in ensuring that the retrieved movies resonate with the user's expressed interests, even when these interests are not articulated well. Furthermore, the use of in-context learning allows the system to maintain its performance without extensive fine-tuning [3], making it both efficient and effective.

The rest of the recommendation system follows the Retrieval-Augmented Generation (RAG) [6] pipeline (see Figure 1). The RAG pipeline operates by first generating textual representations of movies, which are then embedded into a vector space. These embeddings are stored in a vector database, allowing for efficient similarity searches. When a user submits a query, the system generates a corresponding representation, embeds it into the same vector space, and retrieves the top k most similar movie embeddings from the database. This process ensures that the recommendations are both contextually relevant and semantically aligned with the user's input.

[1]No EON user data was used.

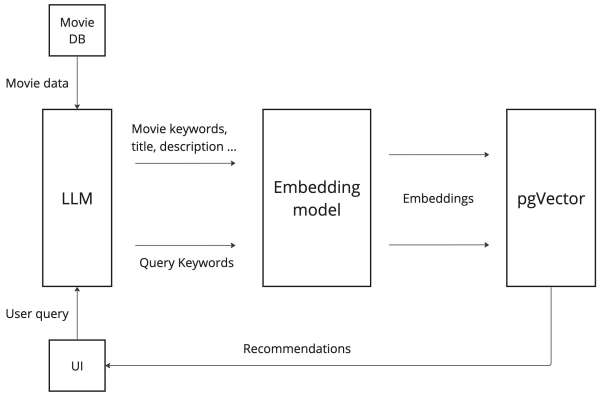

Figure 1: Overview of the Recommendation Pipeline.

4.2 User Interface

Our proposed user interface designs (see Figure 2) offer two main ways for users to interact with our recommendation core. Besides a direct search, where the user submits a query and receives recommendations in a single step, we propose: **(a)** A chatbot, which assists users in narrowing down their options through a conversational interface. The chatbot provides recommendations at each response, allowing for a multi-step interaction that refines the search results progressively. **(b)** An inquisitive method, where an agent asks the user a series of Yes/No questions to narrow down the search. Keywords are generated based on the user's responses, making it particularly useful for users who are uncertain about what they want to watch. This approach shifts the burden of knowing what to query from the user to the system, streamlining the recommendation process.

Each of these designs aims to enhance user engagement and satisfaction by providing tailored interactions that cater to different user preferences and needs.

5 Evaluation

We have developed a twofold approach for addressing the evaluation of our model:

First, to gauge the effectiveness of our keyword-based approach for recommendation, we curated a small multilingual evaluation dataset to test our core recommendation mechanism. This dataset includes queries in various languages along with their expected recommendations. We compared the performance of our mechanism with a baseline RAG system that directly embedded user queries and movie descriptions.

Second, to assess the efficiency and user satisfaction of our system in real-world situations, we have devised an evaluation plan to test our system in production. This strategy utilizes a structured A/B testing framework to conduct precise comparisons between our semantic recommendation system and conventional search, addressing distinct aspects of user experience and system performance.

5.1 Evaluation dataset

To create our evaluation dataset, we carefully selected 25 movies across multiple languages, including both well-known and lesser-known titles. For each movie, we formulated two types of queries to assess the system's retrieval accuracy: *Descriptive* and *General* queries.

The *Descriptive* queries were designed to simulate scenarios where the user knows exactly what they are looking for. For instance, a query for the movie *Messi (2014)* might be, "I am looking for inspirational documentaries about famous athletes, such as Lionel Messi and his rise through football." In contrast, the *General* queries were intended to test situations where the user has only a rough idea of what they want to watch, which is likely more common in real-world environments. An example of a general query for the same movie might be, "soccer movies that will inspire me."

To evaluate the system's performance across different linguistic contexts, we manually translated these queries into English, Serbian, and Slovenian. We then compared the performance of our keyword-based retrieval mechanism against a baseline RAG model that directly used user queries and movie descriptions without generating keywords.

5.2 Experiment Design

We have divided our user base into four distinct groups to facilitate a detailed comparative analysis, aligned with our proposed user interface designs:

Baseline Group: This control group doesn't use our system, but instead finds movies and receives recommendations based on the traditional recommendation methods, a common practice in the industry.

Direct Semantic Search Group: This control group interacts with a straightforward search interface. Users submit a query and receive recommendations in a single step. This approach provides immediate suggestions based on the user's input, mimicking traditional full-text search practices.

Chatbot Group: Participants in this treatment group use a conversational interface (interface **a**), where a chatbot assists in narrowing down options. The chatbot provides recommendations at each response, enabling a multi-step interaction that progressively refines the search results. This design enhances engagement by simulating a natural conversation.

Inquisitive Method Group: Users in this group engage with an agent that asks a series of Yes/No questions to narrow down the search (interface **b**). Keywords are generated based on the user's responses.

The evaluation will be conducted continuously, starting with a focused initial phase over the first month post-implementation to address immediate usability and performance issues, followed by ongoing monitoring to capture long-term user engagement and satisfaction.

By implementing this structured evaluation framework, we aim to comprehensively understand the impact and effectiveness of our semantic recommendation system, guiding further refinements and ensuring that the system meets user needs and expectations.

5.2.1 Metrics We would like to measure how users interact with our system in two main ways: First, we would like to know how engaged and satisfied they are with our recommendations, i.e., do users find our system frustrating to navigate, and whether they watch movies recommended by our system. The second set of metrics will aim to capture how different demographics interact with our system, as a major goal is to remove any biases such as language or age.

Engagement and Satisfaction Metrics: These include Click-Through Rate (CTR), which measures the percentage of clicked recommendation links, and Watch Time to gauge the duration users engage with recommended content. Additionally, immediate user reactions are captured through Like/Dislike Ratios, while more detailed user feedback is collected via surveys administered after interactions.

Behavioral Metrics: We analyze User Interaction Patterns, such as search frequency and refinement actions, and System Usage Frequency to determine how different demographics utilize the system and to identify any potential biases in system engagement. We also record the search time and number of queries needed for a decision.

6 Results

The outcomes presented in Table 1 showcase the performance of both models in various query types and languages, as measured by accuracy at the top 5 and top 10 recommendations.

The results reveal that the baseline model surpasses (or matches) the performance of the keyword mechanism in the case of *Descriptive* queries, particularly in terms of Accuracy@5. However, in terms of Accuracy@10, the two models demonstrate relatively similar performance. Conversely, the keyword model shows significant performance enhancements for *General* queries, particularly in Accuracy@10, indicating its capacity to adapt to non-specific content descriptions. Additionally, the keywords model consistently performs well across different languages, whereas the baseline model shows fluctuations of up to 28% across languages.

In summary, the keywords model allows for more general and multilingual queries, while the baseline model excels at retrieving very specific content.

Table 1: Evaluation results on the descriptions and general queries data sets. LLM embeddings were generated using OpenAI's *text-embedding-3-large* model. The Keywords model used *GPT-4o*.

	Accuracy@5		Accuracy@10	
	Keywords	Baseline	Keywords	Baseline
Descriptive Queries				
English	60%	**64%**	**68%**	**68%**
Serbian	56%	**80%**	72%	**84%**
Slovenian	56%	**80%**	72%	**84%**
General Queries				
English	**44%**	28%	**68%**	44%
Serbian	44%	**52%**	**68%**	52%
Slovenian	44%	**56%**	**72%**	56%

6.1 User Interface Implementation

We implemented our proposed interface design using Flutter, which guarantees functionality across a variety of devices, including iOS, Android, Windows, and web browsers. This cross-device compatibility is crucial as it ensures that all users, regardless of their preferred platform, have access to our application. The support for mobile devices is particularly useful in our interrogation design, where users can easily navigate through options by swiping cards left or right.

Additionally, we integrated Tipko [1], a Slovenian transcription service, to facilitate voice-to-text capabilities. This feature

enhances user convenience by enabling voice communication with our chat bot, removing the necessity for typing.

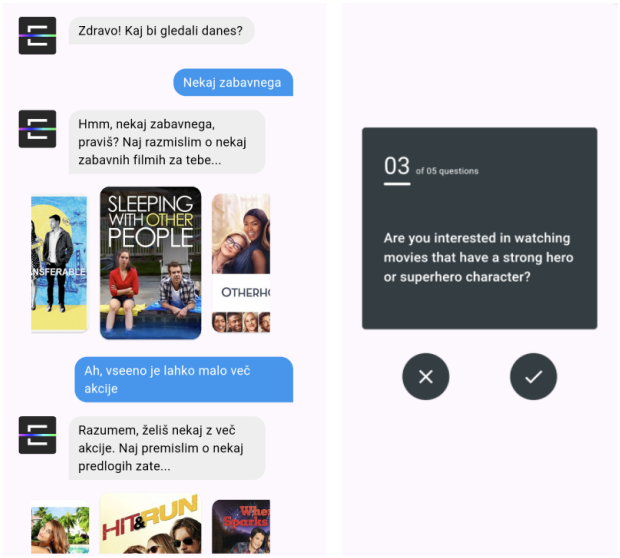

Figure 2: Implementations of our *(a) Chatbot* (left) and *(b) Inquisitive* (right) user interface designs.

7 Discussion

This report introduces a new content recommendation mechanism and three ways to interact with it. Table 1 demonstrates the success of our keyword retrieval model in understanding general user preferences while still performing well when searching for specific content. Moreover, its consistency across languages and its ability to retrieve content using specific descriptions as well as general themes make it well-suited for a diverse user base. Additionally, the keyword model allows seamless integration with both the *Chatbot* and *Inquisitive* methods. Moreover, our system could be extended to dynamically adjust keyword generation based on user-specific factors such as viewing history, local time, weather, and current mood indicators. This personalization ensures that the recommendations are not only relevant to the content but also tailored to the user's immediate context and preferences.

Our approach has some limitations, including the cost per query, which is higher than traditional search, although not exorbitant. Furthermore, our model's performance is commendable given our limited knowledge about the movie content but relies on the assumption that the language model may have more information about a movie than our dataset. It's worth noting that, in the short term, it appears that models are continually improving, becoming faster, more knowledgeable, and more cost-effective.

Lastly, as with any chat application that involves user inputs, security is a crucial consideration. While improvements can be made through better prompting and fine-tuning, ongoing monitoring is essential when the system is in production.

8 Future work

In future work, we plan to further explore methods for improving user experience and personalization. Our initial experiments have involved incorporating the user's time, location, and weather to enhance results. Moving forward, we aim to explore additional integrations, such as the user's calendar. We also intend to expand our user interface by introducing new forms of interaction, such as movie trailers and multiple-choice questions.

To overcome the limitations of our movie information, we are interested in delving deeper into the content by analyzing subtitles using a local language model. Additionally, we aim to broaden our database to include other types of content, such as live channel content and special time-limited events like Eurovision, Eurobasket, and the FIFA World Cup.

Finally, we are interested in the integration of a traditional recommendation models that utilize historical watch data or ratings to re-rank our recommendations.

Acknowledgments

This project was made in collaboration with United.Cloud and In516ht for the 2024 Data Science Competition, organized by The Faculty of Computer and Information Science at the University of Ljubljana. We thank our advisors Slavko Žitnik, Aljaž Košmerlj, Klementina Pirc, and Rebeka Merhar for their contributions.

ABSTRACT

This paper solves the problem of estimating the number and type of required resources for pickup and delivery of passengers at some time in the future. By combining optimization and sampling methods, as well as making plans based on several statistical samples, we estimate the real values for the required resources and show how the sample values converge towards the real values. Our approach combines machine-learning based demand predictions, for the number of passengers, and a route optimization engine that assigns the passengers into shared shuttle vehicles. In order to validate our method we create a baseline data that is representative of the real values. We test our approach using this baseline data, and we obtain statistically significant results.

statistical samples, demand predictions, route optimization engine, sampling techniques, optimization technique

1 INTRODUCTION

The effective allocation of resources is a critical topic in the mobility industry. Anticipating the number and type of resources required can significantly enhance a company's ability to plan accurately for the future. Our work addresses this challenge by focusing on how to estimate the number and type of vehicles needed for passenger pickup and delivery at a future time. The input to our problem consists of machine learning-based demand predictions, which provide estimates of the number of passengers across various routes offered by the company. These predictions are provided daily and further broken down into hourly estimates for each day.

Once we receive these predictions, our goal is to simulate reservations based on this data. For instance, if the predictions indicate that 12 passengers will travel from Ljubljana to Koper on October 20, 2024, we would simulate reservations using sampling techniques. One particular example is creating four separate bookings—one for five passengers, one for three, and two for two passengers each. We will introduce the sampling techniques used in this process in greater detail later on.

After generating these reservations, the next step is to input them into the Route Optimization Engine to generate a plan for that day. This plan will specify the number of vehicles required and the specific reservations each vehicle will serve.

The main hypotheses that our approach explores and experimentally tests are the following:

- H1: We can accurately estimate the number of required resources using optimization methods based on predicted passenger numbers.
- H2: Monte Carlo sampling of historical distributions can effectively model uncertainty in demand predictions, leading to stable resource estimations.
- H3: Creating plans based on several sample values will converge towards the actual number of required resources.

On the other hand, the key assumptions and limitations that underline our research are:

- Prediction Accuracy: We assume that the predictions effectively estimate the number of future passengers.
- Passenger Distribution: We assume that the number of passengers follows a Poisson distribution and that the distributions on different routes are independent.
- Independence: We assume that the passenger distribution and the window type distributions are independent to each other.
- Concept Drift: We assume there is no concept drift in the data, meaning the underlying data patterns do not change over time.

2 RELATED WORK

The problem of resource allocation in the mobility industry, particularly in the context of vehicle routing and passenger demand prediction, has been extensively studied. Traditional methods for vehicle routing often rely on static models that assume known and deterministic demand. However, recent advances in machine learning and optimization have enabled more dynamic approaches that can account for uncertainty and variability in demand. [3][4] For instance, predictive analytics has been employed to forecast passenger demand using historical data, which can then be fed into optimization algorithms to determine the optimal allocation of vehicles. Monte Carlo simulation is another technique commonly used to model uncertainty in demand predictions, providing a probabilistic framework for decision-making under uncertainty. [2] Moreover, dynamic vehicle routing approaches, have demonstrated the benefits of real-time adjustments to routing plans based on updated demand information. [1] The integration of these methodologies into a continuous planning framework is relatively novel and addresses the limitations of static planning approaches, particularly in highly variable and uncertain environments. [1][5]

3 METHODOLOGY

Our methodology begins with demand predictions for the number of passengers, and the ultimate goal is to determine the number and type of vehicles required, as well as the reservations each vehicle will serve. The figure below provides a detailed overview of this process.

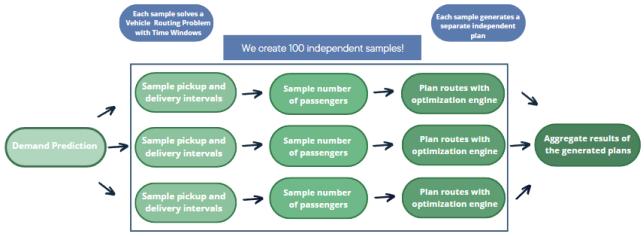

Figure 1. Methodology

Starting with the demand predictions, we apply sampling techniques to simulate reservation data. Specifically, we take the predicted number of passengers for different routes at various times and generate reservations through sampling. This reservation data follows a specific format, including fields such as ID, start location, end location, pickup time, and more. Key attributes include the number of passengers per reservation and the window type, which reflects travel preferences. For instance, some passengers may prefer a private vehicle (VIP), while others are open to sharing the ride. Additionally, the window interval is crucial—it can be a specific time or a more flexible period, affecting both the service pricing and overall experience. These factors will be incorporated into the dynamic pricing model later on.

The process begins with demand predictions and culminates in the generation of reservation data. Critical steps include sampling the number of passengers per reservation, the window type, and the window length. Sampling is done from probabilistic distributions derived from historical data, with the distributions illustrated below.

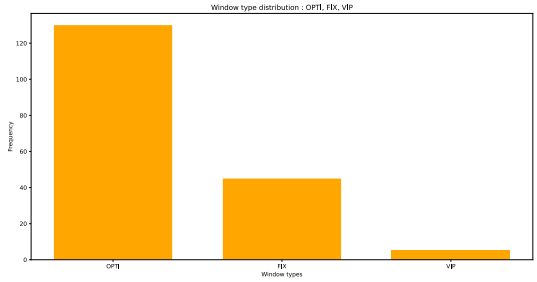

Figure 2. Window type distribution

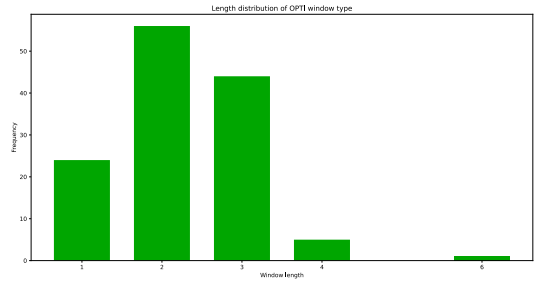

Figure 3. Window length distribution

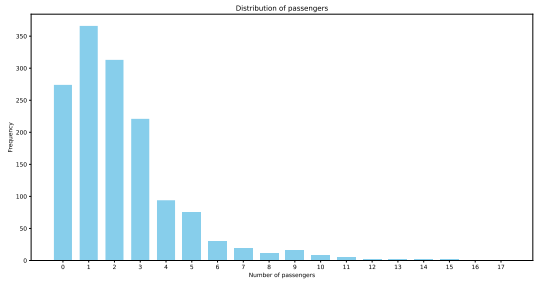

Figure 4. Number of passengers distribution

Please note that from a single demand prediction input file, we generate 100 independent samples of reservation data. This approach introduces uncertainty through probabilistic sampling. Each independent sample is then submitted as a separate job to the Route Optimization Engine, where it solves a vehicle routing problem with time constraints. The output for each job is a plan corresponding to the reservation data. Our final objective is to aggregate these results and analyze the insights they provide.

4 RESULTS

After solving all 100 jobs, we obtained 100 independent plans and began analyzing the results. As shown in the figure below, the distribution of the number of passengers yielded a mean value of 325.87 with a standard deviation of 16.85. For the number of vehicles, the mean was 38.01 with a standard deviation of 3.06. It's notable that the passenger data exhibits significantly more variance compared to the vehicle data. This is expected, as passengers are grouped into visits, and visits are then allocated to vehicles, resulting in less variation in the vehicle count.

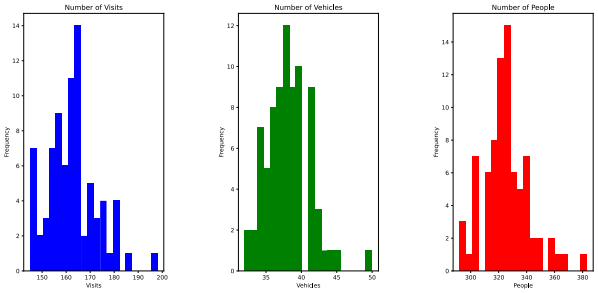

Figure 5. Sampled data: visits, vehicles and passengers distributions

To further validate our approach, we created a baseline using the same data from which the demand predictions were generated. We generated 100 samples from this baseline and submitted them as independent jobs. Upon completion, we compared the baseline results with those of our sampled data. The mean number of vehicles from the baseline was 37.81 with a standard deviation of 3.01, which closely aligns with the values from our sampled data. You can observe the comparison on the figure below.

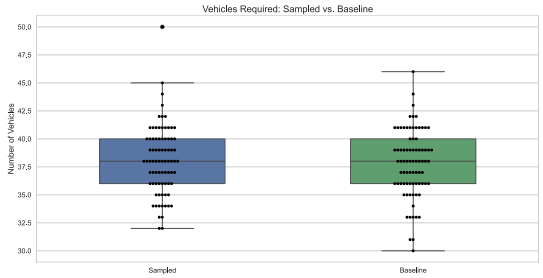

Figure 6. Comparison of required vehicles between sampled and baseline data

We also analyzed the error distribution for the number of vehicles between the baseline and sampled data, finding a mean absolute error of 3.16. This suggests that the difference between the two sets is minor, considering the sampling of data, and it is indicating a good alignment. Additionally, the average number of vehicles in both the sampled and baseline data is quite similar. While the mean absolute error reflects some variability in the sampled values, this is acceptable given the overall similarity to the global mean, and the sampling of values. Thus, despite the variance, the sampled values converge towards the actual values. This error distribution is displayed on the figure below.

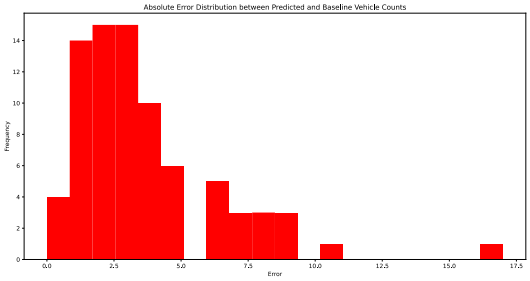

Figure 7. Required vehicles - error distribution

To statistically test whether the sampled and baseline data have the same mean number of vehicles, we conducted a Welch's t-test. The results showed a test statistic of 0.59, a p-value of 0.55, and a 95% confidence interval ranging from -0.64 to 1.23. Given the p-value, we fail to reject the null hypothesis, meaning there is no statistically significant difference between the sampled and baseline vehicle counts. Additionally, the range of the mean difference of vehicles between the sampled and the baseline data, which is from - 0.64 to 1.23, falls within our practical significance threshold of up to 2 vehicles, further supporting the similarity between the two datasets. This indicates that we can effectively estimate the number of required resources by applying optimization techniques on top of the demand prediction values.

We also analyzed the mean number of vehicles and observed that this value converges toward the actual values as the number of samples increases. This is shown on the figure below.

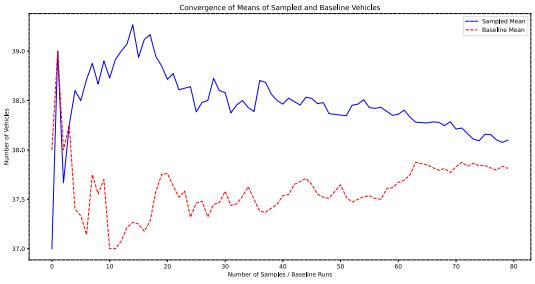

Figure 8. Convergence of means of sampled vehicles

Finally, after obtaining both the number of passengers and the number of vehicles, we decided to fit a linear regression to explore whether we could simplify the process and avoid the detailed approach previously described. As illustrated in the figure below, the regression line serves as a reasonable estimator for the number of vehicles based on the number of passengers. However, this model struggles to capture the non-linear relationships influenced

by various optimization types, window lengths, and travel modes, resulting in considerable variance around the regression line. While it is generally true that a higher number of passengers correlates with an increased number of vehicles, this relationship can be misleading. Different travel types can accommodate more passengers per vehicle, which can disrupt the linear relationship, especially in cases where these travel types dominate. Consequently, although the linear regression provides a solid approximation, it overlooks essential non-linear factors that are critical to our analysis. Our approach, which integrates these factors, demonstrates greater robustness and effectiveness. The linear regression line and the data correlation are presented in the figure below.

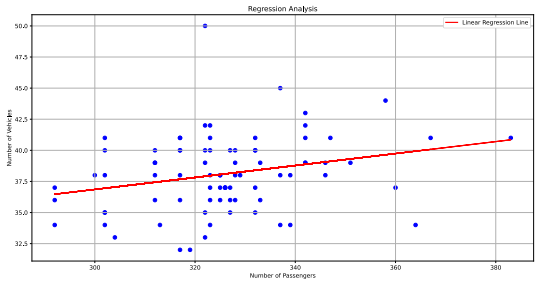

Figure 9. Regression Analysis

5 CONCLUSION

In conclusion, our findings demonstrate that we can effectively estimate the number of required resources by employing optimization methods based on predicted passenger numbers. As the number of samples increases, the sampled values consistently converge toward the actual resource requirements, reinforcing the reliability of our approach. Alternative methods, such as linear regression, fail to adequately address the non-linear complexities inherent in resource allocation, such as varying optimization types and window lengths. Our method, which incorporates these factors, proves to be a far more accurate and effective solution for resource estimation in the mobility industry.

ACKNOWLEDGMENTS

Our research is part of a broader, multi-partner initiative called CONDUCTOR. The primary objective of this project is to design, integrate, and demonstrate advanced, high-level traffic and fleet management systems. These systems aim to optimize the transport of passengers and goods efficiently on a global scale, ensuring seamless multimodality and interoperability. The CONDUCTOR project is co-funded by the European Union's Horizon Europe research and innovation programme under the Grant Agreement No 101077049.

ABSTRACT

The advent of Large Language Models (LLMs), such as ChatGPT and GPT-4, has revolutionized natural language processing, opening avenues for advanced textual understanding. This study explores the application of LLMs in developing Knowledge graphs from textual data. Knowledge graphs offer a structured representation of information, facilitating enhanced comprehension and utilization of unstructured text. We intend to construct Knowledge graphs that capture relationships and entities within diverse textual datasets by harnessing LLMs' contextual understanding and language generation capabilities. The primary goal is to explore and understand how well LLMs can identify and extract relevant entities and relationships from textual data using prompt engineering while contributing to structured knowledge representation.

KEYWORDS

Knowledge graph, Large Language Models, prompt engineering, information extraction, textual data

1 INTRODUCTION

In an era where data is ubiquitous, efficient organization, retrieval, and interpretation of textual information are crucial. Knowledge graphs, representing facts and relationships in structured forms, play a pivotal role in various AI applications, from enhancing search engines to powering recommendation systems. However, the construction of these graphs is often hindered by the complexity and variability of human language. This paper explores the potential of Large Language Models, like GPT-4, to revolutionize this process. By leveraging their advanced natural language understanding capabilities, we aim to automate and refine the extraction of knowledge from textual datasets. The fundamental purpose of this research is to understand the extent to which LLMs can identify and extract relevant entities and relationships from textual data and then build a Knowledge graph using the extracted information.

The motivation behind this study stems from the growing need to effectively manage and utilize the vast amounts of textual data generated daily. Knowledge graphs offer a structured and intuitive way to represent information, but their construction is often labor-intensive and requires expert knowledge. However, constructing Knowledge graphs from unstructured text is intricate and depends on sophisticated natural language processing (NLP) methods, including named entity recognition (NER) and relation extraction. The advancement of LLMs like GPT-4 presents an opportunity to automate and improve this process as illustrated in Figure 1. Utilizing LLMs can lead to more efficient, scalable, and accurate Knowledge graph construction, thereby unlocking new possibilities in information management and AI applications.

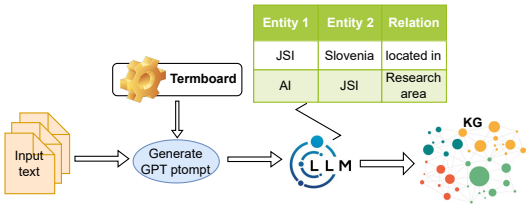

Figure 1: Overview of proposed approach where input text is processed through a Termboard to generate a structured prompt for LLM, creating an entity-relation table to build a Knowledge graph (KG).

2 BACKGROUND

An overview of recent research in Large Language Models and Knowledge graphs is provided in this section, which also emphasizes the potential for their integration.

2.1 Large Language Model (LLM)

Large Language Models are advanced AI systems pre-trained on extensive data, enabling them to comprehend and produce human language. Their recent surge in popularity is due to their proficiency in various language-processing tasks, including text completion, translation, summarization, and answering questions. These models, primarily based on transformer architecture, utilize self-attention mechanisms through encoder-decoder modules. Encoders transform input text into numerical embeddings that reflect the context and meaning, while decoders use these embeddings to generate coherent and pertinent textual output. The large language models feature a decoder-only architecture and, thus, make a prediction of the target output text using only the decoder module. The training paradigm for these models is to predict the next word in the sentence. Generally, large-scale decoder-only LLMs such as ChatGPT [7] and GPT-4 [2], focus on human-like language output, predicting subsequent words based on the preceding text for tasks like text generation.

Table 1: Simplified comparison between Large Language Models (LLMs) and Knowledge graphs (KGs)

Feature	LLM	KG
Knowledge type	Broad, general knowledge	Structured, domain-specific knowledge
Data handling	Flexible, can process varied inputs	Requires structured data
Accuracy	May lack precision in understanding	Highly accurate with structured data
Understanding	Can interpret and generate language	Designed for specific queries and relationships
Adaptability	Adapts to new information by retraining	Adaptable when updated with new data
Transparency	Often seen as "black boxes" with unclear reasoning	Clear decision-making pathways
Error rate	Can make mistakes due to broad generalizations	Can be prone to errors if data is incorrect or missing
Complexity	Handles complex language tasks	Manages complex relationships and attributes
Usage	Broad applications in text generation, translation, etc.	Used for specific tasks like recommendations, search optimization
Scalability	Scales with computational power	Scales with the amount of structured data available

2.2 Knowledge graph (KG)

Knowledge graphs are structured representations of information that depict the relationships between entities in a specific domain. They are used extensively in various applications, such as search engines, recommendation systems, and question-answering systems. These graphs use detailed connections between data to help with smart thinking, finding specific information easily, and running applications that use knowledge. Hence, allows us to better understand and use information across multiple fields.

Knowledge graphs provide a structured way of representing interconnected knowledge. They are precise and consistent, aiding in decisive and informed decision-making. KGs are particularly valuable for their interpretability and explainability due to the explicit representation of entities and relationships. They can capture domain-specific information accurately and evolve to incorporate new data. However, KGs may suffer from incompleteness and may not always reflect the most recent or unseen facts. They also typically cannot understand natural language in an unstructured format [3][6]. Moreover, KGs are preferred in scenarios where explainability and interpretability are crucial, as they provide structured knowledge representation.

2.3 Combining LLM and KG

The comparison between Large Language Models and Knowledge graphs (Table 1) can be supported by various references that highlight their respective strengths and weaknesses [4]. Large Language Models like ChatGPT [7] are celebrated for their generalizability and ability to process diverse text data, allowing them to perform various language-related tasks without extensive task-specific training. They can act as reservoirs of general knowledge, aiding in information synthesis and research. Their proficiency in language processing is useful in tasks like natural language understanding and sentiment analysis. However, they can suffer from hallucinations, where they generate plausible but factually incorrect information. Their "black-box" nature makes it difficult to understand the internal decision-making processes, and they can be indecisive, producing uncertain responses to ambiguous inputs. Additionally, while they have vast general knowledge, they may not be up-to-date with domain-specific or the latest information. Critics of LLMs argue that these models lack transparency and interoperability.

Recent research [3] [4]efforts are, however, improving LLM's interpretability through techniques like attention mechanisms and model introspection. KGs also present advantages over LLMs by providing knowledge about long-tail entities, thus improving recall for knowledge computing tasks. However, both LLMs and KGs can perpetuate biases present in their training data or construction methodologies. In conclusion, both LLMs and KGs have their unique strengths and challenges. While LLMs excel in general language processing and knowledge extraction from vast corpora, KGs provide a structured and interpretable way to organize explicit knowledge. These differences underscore the potential benefits of integrating LLMs and KGs to create more robust AI systems that leverage the strengths of both approaches.

3 PROOF OF CONCEPT: ANALYSIS AND KNOWLEDGE GRAPH GENERATION

This section demonstrates how to process and analyze textual data to build a Knowledge graph using LLM. It is important to mention that prompt engineering [5] is of great importance when it comes to the results generated from ChatGPT. Since it is a generative model, small variations in the input sequence can create large differences in the produced output as demonstrated below. We use two different textual files containing contextual data: (i) APRIORI proposal (containing project details, job description, potential candidate skills, hosting organizations, etc.) and (ii) ADRIA Motorhome instruction manual (containing textual as well as tabular data). Moreover, building KG out of the ADRIA instruction manual has potential applications for the manufacturing industry.

3.1 Using ChatGPT Prompts:

We compare ChatGPT-3.5 and GPT-4 extracted entities and relations using the same prompts. We use Termboard[1] which offers customized ChatGPT prompts to create terms, entities, and relations to visualize larger graphs from the provided text.

Prompt: Extract an ontology and create a table of relations with 3 columns in this order: source, target, and relation name. Also Create a table with 2 columns: put in the first column the name of the term and in the second column an elaborate definition of the term. Use this text as a basis: ¨APRIORI¨- (contains textual data about the job description, candidate skills, project description, hosting organization, etc).

Observing the Knowledge graphs generated by ChatGPT-3.5 (Figure 2) and GPT-4 (Figure 3); we notice, that it didn't extract all entities and relations and missing terms/concepts. For this reason, we ran the second prompt, where we redefined a more detailed prompt to ask GPT-4 to explicitly generate a comprehensive ontology including all entities and relations from the provided text, categorize entities into types like Persons, Organizations,

[1]https://termboard.com/

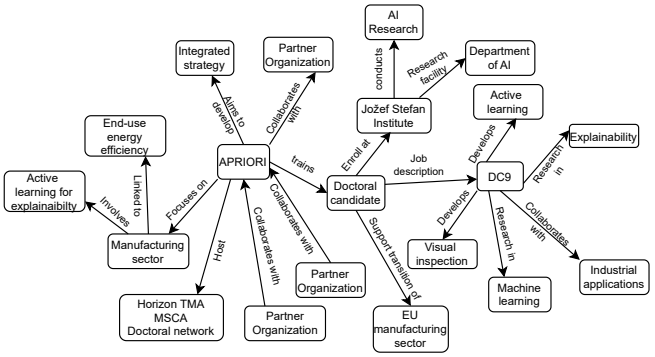

Figure 2: The KG generated using ChatGPT-3.5 contains 20 entities. It was able to extract entities and link them to relations, but it failed in abstracting concepts and specifying entities (i.e. partner organizations, location, etc.).

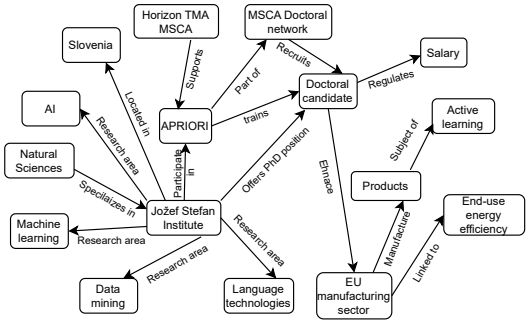

Figure 3: The KG generated by GPT-4 contains 16 entities. It was able to identify abstract concepts, and geographic entities that ChatGPT-3.5 doesn't. Extracted more elaborated entities with relations.

and concepts, and Geographic Locations, and then identify the relations between these entities. Providing additional information to GPT-4 resulted in an improved Knowledge graph (Figure 4). However, ChatGPT-3.5 didn't produce a quality graph (Figure 5) compared to Figure 2.

3.2 Python Implementation

We use a free, open-source library called spaCY [2] for advanced NLP in Python. We employ the named entity recognition technique to identify named entities from a given text using the spaCY model (en-core-web-sm). We used a chunk of textual data from the ADRIA Motorhome manual for experiment purposes. Table 2 compares entities, relations, and triplets extracted from the raw texts. The table shows that the number of triplets extracted by algorithms is similar–(Figure 6 and Figure 7). However, the number of entities that spaCY extracts are larger but not every pair of entities is connected by meaningful relation, leading to fewer triplets. Thus defeating the purpose of creating a Knowledge Base. When using spaCy for entity extraction, the entities are typically recognized based on the named entities present in the text. Named entities are often specific nouns, such as names of people, organizations, locations, dates, or product names. spaCy might not identify it as a specific entity by default. So to extract specific entities, it might need to customize spaCy's NER model

[2]https://spacy.io/models

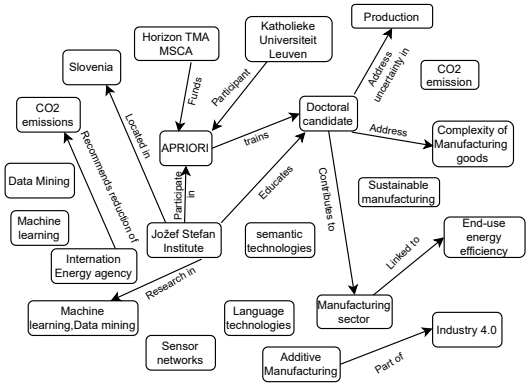

Figure 4: The KG generated by GPT-4 contains 22 entities. It Identified more key entities and relevant concepts and identified suitable relations to connect them (i.e. participant-Katholieke Universiteit Leuven). However, it didn't cover all relations and classes (i.e. skills). We also notice a few duplicated entities(i.e. data mining, CO2 emission, etc.) and some independent entities (i.e. sustainable manufacturing).

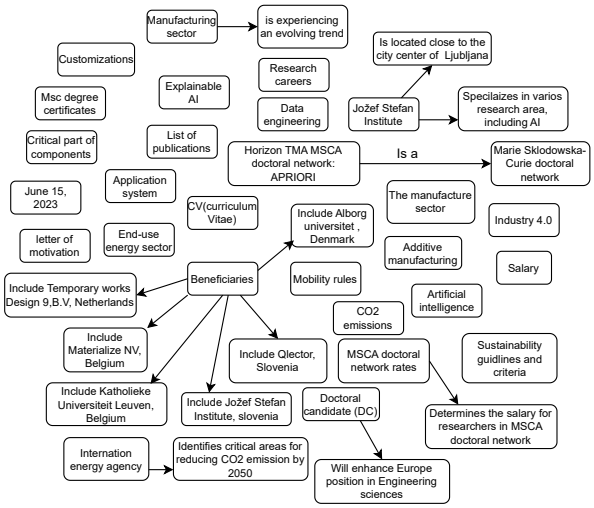

Figure 5: ChatGPT-3.5 was able to extract a larger number of entities but it was not successful at abstracting concepts and missing relations. Entities and relations found frequently represented complete sentences rather than concepts. This occurs because ChatGPT is a conversational model trained on a task to create responses to a given prompt and is not particularly trained to recognize entities and relations

or provide additional context for better recognition. Hence results can be improved by pre-processing data into a structured format.

4 EVALUATION

When there is no ground truth data available, creating an automated evaluation metric for a Knowledge graph becomes challenging. In such cases, the evaluation relies on qualitative principles to assess the results. Based on the practical framework defined in the study [1], the following principles were identified:

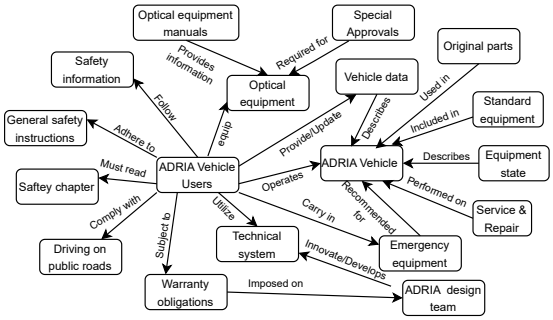

Figure 6: The KG generated by GPT-4 contains 18 entities using the ADRIA motorhome instruction manual. It extracted concepts relevant to ADRIA users and vehicle instructions, their functions, and how they are connected.

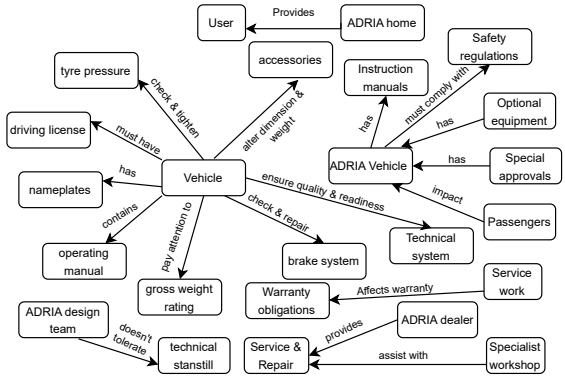

Figure 7: The KG generated by ChatGPT-3.5 contains 24 entities. Extracted more entities relevant to ADRIA vehicles but relations between entities are more generic and entities are duplicated.

- Triplets should be concise.
- Contextual information of entities should be captured.
- The Knowledge graph does not contain redundant triples.
- Entities should be densely connected.
- Relations among different types of entities should be included.
- Knowledge graphs should be organized in structured triples for easy processing by machine.
- For tasks specific to a particular domain, it's essential that the Knowledge graph is tailored and relevant to that specific field

According to these principles, in our use case, we manually inspected the Knowledge graphs generated above, and we can conclude that the ChatGPT-3.5 approach provides a more detailed Knowledge graph without abstract concepts compared to the GPT-4. However, to create these Knowledge graphs, a few steps of refining the answers from ChatGPT are needed. Sometimes the produced output is incorrect and needs to be corrected before proceeding. When we redefined the prompt, GPT-4 identified more specific entities, and concepts compared to ChatGPT-3.5. Even though ChatGPT extracted a larger number of entities, it failed to provide abstract concepts and entity-relation.

In the second part of the experiment, we employed the NER method to extract relations and entities from the given text (i.e. ADRIA). We analyzed that extracted entities are duplicated and relations have some noise and incomplete information. If you have specific patterns or structures in mind that you want to extract entities and relations based on, you may need to customize the relation extraction logic. Alternatively, more advanced natural language processing techniques or pre-trained models designed for relation extraction tasks might provide better results. Also, we analyzed half of the relations-entities extracted by spaCY and ChatGPT are overlapped.

Table 2: Knowledge extraction comparison. (ADRIA motorhome manual dataset)

Algorithm	Entities	Relations	Triplets
GPT-4	18	20	20
ChatGPT-3.5	24	18	18
spaCY	22	14	17

5 CONCLUSION

The proposed exploration of using LLMs for Knowledge graph extraction holds promise for advancing our understanding of how advanced language models can contribute to structured knowledge representation. This paper explores using LLMs to generate Knowledge graphs out of source documents. We utilized ChatGPT-3.5 and GPT-4 models to generate the Knowledge Graphs for two different textual data and compared the structure of the KGs. GPT-4 performed better as it successfully identified more abstract concepts and key entities compared to ChatGPT-3.5. Therefore, it provides insights into the practical application of LLMs in developing structured knowledge from unstructured textual data, with potential applications in knowledge-based AI applications, paving the way for more effective information processing and utilization. In future studies, we intend to use a more formal framework to evaluate the quality of created Knowledge graphs. Such a framework will allow us to efficiently analyze the quality of KG and provide a standardized method to forecast missing linkages between concepts and relationships within a given domain.

Abstract

In the paper we propose to convert NP-hard combinatorial optimization problems of packing, covering, and tiling types into maximum or k-clique problems. The key step is to come up with a tactically constructed auxiliary graph whose maximum or k-cliques correspond to the sought combinatorial structure. As an example, we will consider the problem of packing a given cube by copies of a brick. The aim of the paper is two fold to illustrate (i) the modeling power and (ii) the feasibility of the clique approach. Since theoretical tools are not readily available to study the effectiveness of the solution of the resulting clique problems we will carry out carefully conducted numerical experiments.

Keywords

mathematical programming, k-clique problems, combinatorial optimization

1 Introduction

One can see graphs as a mathematical models that can describe various fields of interest. Like numbers, functions, or Linear Programming graph based approach can model interesting problems and aid us in solving them. Some of these approaches are quite straightforward like cliques of people in a social interaction graphs or shortest path problem in a road map. Other approaches are less obvious but still easily constructed, like conflict graphs in a set of codewords where a maximum independent set represents a maximum set of suitable error correcting codes [9].

But the approach of modeling and solving various problems by graphs are more versatile. Namely, we can see graphs as a language for mathematical programming – if certain combinatorial problems can be solved by constructing a suitable auxiliary graph and finding a maximum or k-clique of this graph gives the solution. The authors have already used this approach in connection with mathematical conjectures [1], hyper graph coloring [11], subgraph isomorphism [2], scheduling problems [12], graph coloring problems [13] and protein docking problems in chemistry [8].

Here we would like to give an example, where a hard combinatorial optimization problem can be solved by this approach. For this we chose a simple to understand but numerically hard to solve problem of brick packing popularized by M. Gardner. We will focus on different approaches of how to construct an auxiliary graph in order that to translate this problems into a clique search problem. We will try to investigate how these different approaches – based on packing, covering and tiling– affect the solving time and if they have other consequences as well. First, we describe the basic problem, then we present theoretical discussion of different reformulations, and finally we describe the results of numerical experiments. The emphasis is on the modeling aspect of the computation and not on reaching new records, as the proposed problem was solved in theoretical manner within months of its formulation. Here we use it as a prototype of similar problems, and our aim to show the versatility of our approach, that is model a problem by a graph.

Graphs in this paper will be finite simple graphs. Further all graphs we use will not have loops or double edges. A finite simple graph G can be described with its set of nodes V and a subset E of the Cartesian product $V \times V$. The subset E can be identified by the set of edges of G.

Let $G = (V, E)$ be a finite simple graph. A non-empty subset C of V is called a k-clique if each two distinct nodes of C are adjacent in G and in addition C has exactly k elements. If C has only one element, then we consider it a 1-clique. The 2-cliques of G are the edges of G. A k-clique C of G is called a maximum clique if G does not have any $(k+1)$-clique. For each finite simple graph G there is an integer k such that G contains a k-clique but G does not contain any $(k+1)$-clique. This well defined integer k is called the clique number of G. We state two clique problems formally.

Problem 1. *Given a finite simple graph G and an integer k. Decide if G has a k-clique.*

Problem 2. *Compute the clique number of a given finite simple graph.*

Problem 1 is a decision problem, it is referred as the k-clique problem, and it is an NP-complete problem included in the original list of 21 NP-complete problems by Karp [7]. Problem 2 is an optimization problem and referred as the maximum clique problem, and as the decision problem belongs to the NP-complete class it follows that it belongs to the NP-hard class.

We color the nodes of a finite simple graph G with the colors $1, 2, \ldots, k$ such that each node receives exactly one color and adjacent nodes never receive the same color. Such a coloring of the nodes of G is called a well coloring, a proper coloring, or a legal coloring (the terminology is not unified). The set of nodes of G receiving the color i is called the i-th color class. Clearly, a color class is an independent

set of G, that is, two nodes from a fixed color class are never adjacent.

If the nodes of a finite simple graph can be legally colored using k colors, then we say that G is a k-partite graph. The reason is that in this situation the nodes of G form a union of k independent sets and these sets are pair-wise disjoint.

In this paper we will focus on the following clique problem.

Problem 3. *Given a finite simple graph G whose nodes are legally colored using k colors. Decide if G has a k-clique.*

Problem 3 is a k-clique problem particularized to case of k-partite graphs. This problem is still an NP-complete problem, as the graph coloring problem can be reduced to such question as shown in [13], and should not be confused with the problem of complete graphs.

The problem class we will be focusing on in the present paper consists of packing, covering, or tiling problems. Obviously many real world and mathematical problems fall into this class, and here we would show some ideas how such problems can be modeled by a suitably constructed auxiliary graph where a k-clique search would solve the original problem.

2 Packing, covering, and tiling

First, we describe the problem class in question. Second, we draw up some basic concepts how these problems can be modeled by graphs.

Let U be a finite ground set and let

$$A_1, \ldots, A_m \tag{1}$$

be subsets of U. A family of subsets

$$B_1, \ldots, B_n \tag{2}$$

with $\{B_1, \ldots, B_n\} \subseteq \{A_1, \ldots, A_m\}$ is called a packing of U if the members of the family (2) are pair-wise disjoint. A family of subsets (2) is called a covering of U if the union of (2) is equal to U. Phrasing it differently, a family of subsets (2) is a covering of U if each element of U belongs to at least one member of the family (2). If a family of subsets (2) is a packing and a covering of U in the same time, then it is called a tiling of U. A tiling of U some times referred as exact covering of U.

A packing of U is called a k-packing if it consists of k subsets of U. Similarly, a covering of U is called a k-covering if it consists of k subsets of U. Finally, a tiling of U is called a k-tiling if it consist of k subsets of U. For a given ground set U and for its given subsets (1) there is an integer k such that U has a k-packing using subsets of the family (1) but there is no any $(k+1)$-packing of U using members of the family (1). This well defined integer k is the packing number of U with respect to the family (1). If the packing number of U is equal to k, then each k-packing of U is called maximum packing of U.

For a given ground set U and for its given subsets (1) there is an integer k such that U has a k-covering using subsets of the family (1) but there is no any $(k-1)$-covering of U using members of the family (1). This well defined integer k is the covering number of U with respect to the family (1). If the covering number of U is equal to k, then each k-covering of U is called minimum covering of U.

We state five problems related to packings, coverings, and tilings in a formal manner. Given a finite set U and its subsets (1).

Problem 4. *Decide if U has a k-packing using the members of the family (1).*

Problem 5. *Decide if U has a k-covering using the members of the family (1).*

Problem 6. *Decide if U has a k-tiling using the members of the family (1).*

Problem 7. *Compute the packing number of U with respect to the family (1).*

Problem 8. *Compute the covering number of U with respect to the family (1).*

Problem 4 can be reduced to Problem 1. We construct a finite simple graph G. The nodes of G are the members of the family (1). Two distinct nodes A_i and A_j are adjacent in G whenever A_i and A_j are disjoint. A k-clique in G corresponds to a k-packing of U.

Problem 5 can be reduced to Problem 3. We sketch the main points of this reduction. We construct a finite simple graph G. The first type of nodes of G are ordered pairs (B, x), where $B \in \{A_1, \ldots, A_m\}$, $1 \leq x \leq k$. The intuitive meaning of the pair (B, x) that the subset B is the x-th member of a k element family of (1). To the node (B, x) we assign the color x. Two nodes receiving the same color will be non-adjacent in G. Therefore the first type nodes of G are legally colored with k colors.

We are adding second type nodes to G. Namely, we are adding the ordered pairs (A, u), where $A \in \{A_1, \ldots, A_m\}$, $u \in U$ and in addition $u \in A$ holds. The intuitive meaning of the pair (A, u) is that the element u is covered by set A. To the node (A, u) we assign u as a color. Two nodes receiving the same color will not be adjacent in G. Thus the second type nodes of G are legally colored using $t = |U|$ colors. Now if we are locating a $(k+t)$-clique in G, then we select exactly k subsets from (1) and each element of U will belong to at least one of these subsets. The missing part of the construction, what we left for the reader, is how the first and second types of nodes are connected by edges.

Problem 6 can be reduced to Problem 3. As a tiling is a packing and covering at the same time, we can add the packing restrictions, namely not connecting two sets if they intersect, to the second type of nodes. On the other hand – in case of equal size sets –, we do not need to count the used sets, so we won't need the first type of nodes, they can be omitted.

The computational difficulties of the k-packing, k-covering, and k-tiling problems are different. It seems that the covering problems are the computationally most demanding and the tiling problems are the most manageable.

3 Gardner's bricks problem

We picked Gardner's problem because it is intuitive and easy to comprehend among such problems that can be reduced to Problem 3 and so it serves as a good illustration of the kind of clique modeling we are dealing with. We do not claim any originality in connection with the problem. We do not prove any new results. Each of the facts we use are known from the folklore and we present them only

for the reader convenience. The problem was raised by Foregger in March 1975 [10], popularized by Gardner in February 1976 [5], and solved by Foregger and Mather in November 1976 [3].

Let us consider a brick B of dimensions $1 \times 2 \times 4$. The brick B is a union 8 unit cubes whose edges are parallel to the coordinate axis. From some reason unknown for us the brick B is referred as canonical brick. Suppose we have a large supply of congruent copies of B and we want to pack as many as possible into a $7 \times 7 \times 7$ cube C. The cube C is a union of 343 unit cubes. Let us divide 343 by 8 with remainder. As $343 = (42)(8) + (7)$, 43 copies of B cannot be packed into C. M. Gardener advanced the question if 42 copies of B can be placed into C. One can place a copy of B into C in any possible rotated position as long the edges of B are parallel to the coordinate axis. (The answer to this question is actually: No, one cannot place 42 bricks into a cube of size $7 \times 7 \times 7$.)

Gardner's problem can be expressed in terms of computing the clique number of a suitable constructed graph G. In other words, Gardner's problem can be reduced to an instance of the maximum clique problem. Let us denote the set of the 343 unit cubes forming C by U. An 8 elements subset v of U is a vertex of G if the union of the elements of v is a congruent copy of B. As it turns out G has 1008 nodes. Two distinct nodes v and v' of G are adjacent in G if v and v' are disjoint. If G contains a (42)-clique, then 42 congruent copies of B can be packed into C. During our numerical experiments a greedy coloring procedure provided a legal coloring of the nodes of G using 42 colors. Note that this is just a coincidence, it could've happened otherwise. Thus we are facing with a particular case of the k-clique problem stated in Problem 3. The nodes of G are legally colored with 42 colors and we are looking for a (42)-clique in G. Phrasing it differently, we are looking for a k-clique in a k-partite graph, where $k = 42$.

We introduce a coordinate system whose origin coincides with a corner of the cube C.

Observation 1. *If* 42 *congruent copies of the brick* B *can be packed into* C*, then there is such a packing which contains the congruent copy of* B *whose one corner is the origin. Further the edges of lengths* 1*,* 2*,* 4 *are parallel to the first, second and third coordinate axis, respectively.*

Proof. As $343 = (42)(8) + (7)$ holds, 7 unit cubes of C are not contained by any bricks of the packing. The cube C has 8 corners and so at least one of the corners must be contained by a brick. At this point we introduce a coordinate system whose origin is this corner of C. Then we introduce the first, second, and third coordinate axis to satisfy our requirement. □

The cube C can be sliced into 7 slabs using planes perpendicular to the first coordinate axes. Each slab is a $1x7x7$ slice of the big cube, that is a union of 49 unit cubes. The centers of these cubes are in a plane perpendicular to the first coordinate axis. The 7 unit cubes of C, that are not contained by any brick of the packing, are referred as unpacked unit cubes.

Observation 2. *Two distinct uncovered unit cubes of* C *cannot be in the same slab.*

Proof. Note that a fixed slab can contain only 0, 2 or 4 unit cubes from any brick of the packing. The point is that the numbers 0, 2, 4 are all even. Each slab consists of an odd number of unit cubes. Therefore, each slab must contain an odd number of unpacked unit cubes. The number of slabs is 7 and so each slabs must contain exactly one unpacked unit cube. □

We can also form slabs by slicing C with planes perpendicular to the second coordinate axes. Each of these 7 slabs contains exactly one unpacked unit cube. Finally, slicing C by planes perpendicular to the third axes we get that each of these slabs contains exactly one unpacked unit cubes. These constraints on the uncovered unit cubes are independent, but can also be checked independently during an extended search, and as such can reduce the search space well.

4 Numerical experiments

Gardner's brick packing problem can be turned into various clique search problems and we carried out numerical experiments with them. We will observe that the same geometric problem will lead to very different clique search problems. When we try to pack 42 congruent copies of the canonical brick B into the the big cube C, we get a k-clique problem. When we notice that the nodes of the auxiliary graph can be legally colored using 42 colors we get a k-clique problem in a k-partite graph which is a more tractable search problem. When we try to pack 42 congruent copies of the brick into the cube C together with 7 unit cubes we get tiling problem. When we try to pack 42 congruent copies of the brick into the cube C together with 7 unit cubes and in addition we distinguish the unit cubes among each other we get yet another version of the tiling problem.

In the first approach the auxiliary graph G_1 had 1008 vertices. The nodes of G_1 were legally colored using 42 colors and we tried to locate a (42)-clique in G. Note, that although this graph can be colored with 42 colors it was just a coincidence. There is no theoretical background to this fact. Of course the expectation was that G_1 do not have any (42)-clique.

Let us assume that it is possible to pack 42 congruent copies of the $1 \times 2 \times 4$ canonical brick B into the $7 \times 7 \times 7$ cube C. By Observation 1, we may assume that a brick appear in the packing such that one of the corners of the brick coincides with the origin of the coordinate system and the edges of lengths 1, 2, 4 are along the 1-st, 2-nd, 3-rd coordinate axis. This information can be interpreted such that there a (42)-clique C_2 in G_1 which has a specific node. Namely, the vertex v_1 of G_1 that corresponds to the special corner brick is a node of the of C_2. This suggests to restrict the graph G_1 to the neighbors of the vertex v_1 to get a new graph G_2. Then we are looking for a (41)-clique in G_2. Plainly, the nodes of G_2 are legally colored using 41 colors. This coloring is inherited from the coloring of the nodes of G_1. Since the graph G_2 has fewer vertices than G_1 (actually 960) and we are looking for a smaller clique in G_2 than in G_1. The new clique problem probably requires less computational effort because the graph is smaller, and because we introduced a symmetry breaking to it.

The problem of packing 42 bricks into a bigger cube can be viewed as a tiling problem. Namely, we try to tile the

$7 \times 7 \times 7$ cube C by 42 copies of the canonical brick and 7 additional copies of a unit cube. Thus we are facing to a tiling problem using two different types of tiles and the number of the tiles is given. To ensure that we use 42 bricks we numerate the small cubes as $\{1, \ldots, 7\}$ and ensure in the graph that each small unit cube is used once, that is we do not connect nodes where the unit square is covered by the same small cube. This tiling problem can also be reduced to a clique search problem. We denote the corresponding graph G_3. Tiling problems are more manageable compared with packing problems as during the search back-tracking can be anticipated earlier. However, the graph associated with the tiling in our case has more vertices than the graph associated with the packing, namely it has 10 465 nodes. Therefore only computations can reveal which approach is preferable.

Obviously, in this case we can also fix a brick in the corner. This version will be the G_4 graph.

In the last clique search equivalent of Gardner's problem we construct a graph G_5. In this construction we handle a mixed tiling problem but we utilize the extra information that no two distinct unit cube can appear in the same slab. By Observation 2, this may be assumed. This is done by not connecting two nodes associated with unit cubes if those unit cubes lay in the same slab. This graph is the same size as G_3, as we only delete some edged from it. Also, we can fix a brick in the corner in this case as well, that shall be the G_6 graph.

Once again only numerical experiments can guide us in judging the merits of the possible clique search equivalents of the problems. Further, the preconditioning methods perform differently on the graphs G_1, G_2, G_3, G_4, G_5, G_6 and this adds an extra layer of difficulty to the numerical work. We used a computer with AMD EPYC 7643 processors, `C++`, and gcc v12.1 with settings `-O3 -arch=znver3`.

We made all six graphs and performed k-clique search on them after preconditioning as described in [12, 13]. The preconditioning run for 1-2 hours for the bigger graph, and reduced it by half, namely to around 6 000 nodes for G_3, G_4; and to around 4 000 for G_5, G_6, that is the graphs where we allow only one small cube in a slab. For the smaller graphs (G_1, G_2) the preconditioner runs for a couple seconds but cannot significally reduce the graph. Three of the six graph could be solved after preconditioning: G_2, G_5, and G_6.

The solution time of G_2 (the original graph with fixed brick in the corner) was 50 days. The solution of G_5 was a bit faster, 29 days. Finally, the graph G_6 could be solved more effectively. The running time was 123 484 seconds, that is 34 hours. This clearly show us the importance of the extra information of slabs.

5 Conclusions

We detailed several k-clique search reformulations of a certain combinatorial problem in terms of constructing suitable auxiliary graphs. We do not claim, that these methods result more efficient practical computations than other approaches. The point we are trying to make is that the clique reformulations open up a possibility to use well tuned clique solvers, including preconditioning, to handle different combinatorial problems in a unified manner as a general solver.

The results presented here have interesting consequences and suggest further research problems. First, and as anticipated, different auxiliary graphs lead to very different search space sizes. And although the usual concept in our research is that bigger graphs usually tend to be harder, that is not always the case. Remarkably, numerical results indicate that the size of the auxiliary graph alone is not as important as the type of the reformulation. Namely, the tiling type auxiliary graphs required less computational effort for clique search even if they were not the smallest graphs. Second, there are additional constraints that can be added to some reformulations while they seemingly cannot be incorporated into others. An example to such a constraint is the fact described after the proof of Observation 1. Namely, that no two distinct uncovered unit cubes can appear in the same slab in Gardner's brick packing problem. That kind of restriction could be incorporated into the tiling version of reformulation, and possibly not applicable to the packing reformulation. Taking advantage of the extra constraint made possible to solve the brick packing problem in reasonable time.

There are other problems that can be solved using similar approaches as detailed in the paper. Authors could solve smaller instances of the Golomb ruler problem or the Salem-Spencer set problem. The results, that lay outside the scope of the present paper, obtained with those instances open up even more interesting considerations.

Otvoritveni nagovor

Information Society Multyconference 2024
Conference on Myths and Truths of Environmental Protection
Opening address

V veliko zadovoljstvo in čast nam je, da vas lahko ponovno pozdravimo na letošnji konferenci o okolju v okviru zdaj že tradicionalne Multikonference Informacijska družba. Zahvaljujemo vam, da ste se tako številčno odzvali na naš poziv z vašimi prispevki in predstavitvami.

Tema letošnje konference je kmetijstvo in gozdarstvo v luči nove evropske zakonodaje na teh področjih. Pri tem pa gre za mnogo širše probleme v povezavi z varstvom okolja in podnebnih sprememb, zato je nujno vključiti v razpravo tudi poročila s teh drugih področij, posebej energetike. Ravno tako se ni mogoče izogniti razpravi o nekaterih teoretičnih vidikih, ki so osnova ukrepov za preprečevanje in blaženje posledic podnebnih sprememb.

Podnebne spremembe so postale modni dodatek razpravam, človeški vpliv pa je razglašen za poglavitni vzrok in krivca za vse probleme, ki so se pojavili v zadnjih desetletjih.

Med tem ko spremembe namembnosti zemljišč zagotovo vplivajo na lokalne podnebne razmere, tega pa z enako znanstveno strogostjo ni mogoče trditi za vpliv ispustov toplogrednih plinov na globalni ravni. Med tem ko izpuste toplogrednih plinov spremljamo z nesorazmerno veliko pozornostjo, resne okoljske škode povzročene z drugimi onesnažujočimi dejavniki komaj kdaj omenjamo.

It is a great pleasure and honour to be able to welcome you all once again on behalf of the editorial board of the Information Society Multiconference, and to thank you for your submission of articles and presentations at the Conference on Myths and Truth of Environmental Protection.

This year's main theme is agriculture and forest management in the light of the latest European legislation on this subject. However, as this is just a segment of the much broader problem of both environmental protection and climate change, we have included a number reports on related topics of energy supply and consumption, as well as some theoretical basis for assessing the necessity to mitigate climate change.

Climate change has become a fashion issue during the last couple of decades, and the anthropogenic influence on it has been declared the main cause and a guilt for almost every aspect of problems that have recently emerged in the modern society.

While land use change certainly affects local climate to some extent, the influence of greenhouse gases emissions on global climate has been determined to a much lower certainty than the scientific rigor requires. The question of greenhouse gases has received a disproportionate attention; the question of environmental damage by other pollutants has been discussed only marginally.

Med tem ko je človekov vpliv na podnebje še vedno do določene mere znanstveno vprašljiv, vsaj glede vzrokov ekstremnih vremenskih pojavov, je za večino medijev in politično elito znanost dorečena in je čas za ukrepanje. Podnebna znanost je postala močno politizirana.

Po besedah Rimskega kluba, vplivnega idejnega podnebnega združenja ter svetovalnega telesa Organizacije združenih narodov:

"*Skupni sovražnik človeštva je človek. Pri iskanju novega nasprotnika, ki naj bi nas poenotil, smo prišli do spoznanja, da so onesnaževanje, ogrožajoče podnebne spremembe, pomanjkanje vode in hrane, ter življenja nasploh, ustrezni dejavniki nevarnosti, ki jih s svojim delovanjem povzroča človek. Le s spremembami naravnanosti in obnašanja lahko te nevarnosti prebrodimo. Resnični sovražnik je človeštvo samo.*"

"*Človeštvo je odprlo vrata pekla*", je v svoji nedavni konferenci za novinarje povedal generalni sekretar Združenih narodov Antonio Guterres.

Po drugi strani pa najnovejše Šesto poročilo IPCC v poglavju 11 na strani 1520 oznanja:

"*Pogostost prihodnjih sicer redkih, toda udarnih dogodkov povezanih s podnebnimi skrajnostmi je na splošno povezana z nizko verjetnostjo, čeprav jih ni mogoče izključiti, zlasti ob globalnem segrevanju nad 4°C.*"

In še na strani 1608:

"Če povzamemo; *posamezne povezave med spremembami povprečnih in skrajnih pogojev so močno odvisni od opazovanih dejavnikov ali pojavov. Na lokalni ravni so spremembe povprečnih in skrjnih temperatur površja močno povezane, med tem ko je povezava sprememb povprečnih in skrajnih padavin pogosto šibka. Oboje, spremembe povprečnih in skrajnih pogojev, se močno razlikujejo med različnimi območji zaradi učinkov lokalnih in regionalnih procesov.*"

While the science of human influence on climate is still controversial to some extent, at least in regard to its impact on the frequency and intensity of extreme weather events, for the mass media and most of the political elite the science is settled and it is now time for action. Climate science has become highly politicized.

In the words of the Club of Rome, a premier environmental think-tank, consultants to United Nations:

"*The common enemy of humanity is men. In searching for a new enemy to unite us, we came up with the idea that pollution, the threat of global warming, water shortages, famine, and the life, would fit the bill that dangers are caused by human intervention. It is only by changed attitudes and behaviours that they can be overcome. The real enemy is humanity itself.*"

"*Humanity Has Opened the Gates of Hell*" is one of the recent statements at a press conference by the UN Secretary General Antonio Guterres.

On the other hand, the latest IPCC Sixth Assessment Report acknowledges in Chapter 11, page 1520:

"*The future occurrence of low-likelihood, high-impact events linked to climate extremes is generally associated with low confidence, but cannot be excluded, especially at global warming levels above 4°C.*"

And on page 1608:

"*In summary, the specific relationship between changes in average and extreme conditions strongly depends on the variable or phenomenon being considered. At the local scale, average and extreme surface temperature changes are strongly related, while average and extreme precipitation changes are often weakly related. For both variables, the changes in average and extreme conditions vary strongly across different places due to the effect of local and regional processes.*"

V zanjem času so podnebne spremembe povzročile tudi problem uveljavljana zakonov. Predlagane rešitve za omilitev domnevnih groženj pogosto ustvarijo več novih problemov, rešujejo pa jih malo ali nič. Predlagana zakonodaja pa pogosto povzroča ravno nasprotne učinke, kar je postalo očitno zlasti pri vplivih na avtomobilsko in drugo težko industrijo, kot tudi na poljedeljstvo in gospodarjenje z gozdovi.

Največji problem pa verjetno leži v popolnem pomanjkanju komunikacije in dialoga med vladami in prizadetimi deležniki. Zato je to prvo kar moramo spremeniti, če želimo uveljaviti realne rešitve za realne probleme.

Upamo, da bo ta konferenca korak v to smer.

Konferenčni uredniški odbor
Ljubljana, 9. Oktobra, 2024

Lately the question of climate change has become also an executive problem. Solutions suggested to mitigate the alleged problems often produce more new problems, while solving little or nothing. And the proposed legislation is often counterproductive, which has become evident mostly in its impact on automotive and other heavy industry, as well as on agriculture and forest management.

Probably the greatest problem is a complete lack of communication and dialogue between the governments and the affected parties, and this needs to change first, if we are to establish real solutions to real problems.

Hopefully this conference will be a step in that direction.

Abstract

Life cycle assessment (LCA) has been established as the standard method for evaluating environmental impacts of products, and processes. However, ISO standards depicting the application of these standards are tailored more towards LCA practitioners and less on the data acquisition and quality. The data acquisition process lacks robustness, with significant decision-making and quality control entrusted to practitioners. Given the lack of incentives for industry participants to submit high-quality data, the integrity of LCA databases may be questionable. Moreover, in some cases, participants may be incentivised to protect their data from competition. To address these concerns, data is carefully studied by external experts to verify their credibility. However, it is not entirely clear how these experts are chosen, nor how trust is established. In this paper, we apply a well known method Law of anomalous numbers, commonly referred to as Benford's law in order to test the conformity of commonly used LCA databases. Our results on testing Ecoinvent, one of the most widely used LCA databases, show that LCA data strongly conforms to Benford's law. Moreover, our analysis includes 5 additional publicly available LCA databases, which also conformed with the exception of Bioenergiedat, which is likely due to the low number of observations. Finally, we tested individual properties given by Ecoinvent and establish that very few columns (<5%), which pass the criteria for Benford's analysis, are non-conforming. Although interesting, these results call for a more fine-grained analysis as future work.

Abstract

Življenjski cikel izdelka (LCA) se je uveljavil kot standardna metoda za ocenjevanje okoljskih vplivov izdelkov in procesov. Vendar pa so standardi ISO, ki določajo uporabo teh metod, bolj prilagojeni strokovnjakom za LCA in manj usmerjeni v pridobivanje kakovost podatkov. Proces pridobivanja podatkov ni zelo robusten, saj je veliko odločitev in nadzora nad kakovostjo prepuščenih izvajalcem. Glede na pomanjkanje spodbud za udeležence iz industrije, da oddajo kakovostne podatke, je lahko integriteta baz podatkov LCA vprašljiva. Poleg tega so udeleženci v nekaterih primerih lahko motivirani, da zaščitijo svoje podatke pred konkurenco. Da bi naslovili te pomisleke, podatke natančno preučijo zunanji strokovnjaki, da bi preverili njihovo verodostojnost. Vendar ni povsem jasno, kako so ti strokovnjaki izbrani in kako se vzpostavlja zaupanje. V tem prispevku uporabljamo dobro znano metodo "zakon anomalnih števil", pogosto imenovano Benfordov zakon, da bi preizkusili skladnost podatkov, ki se uporabljajo v najpogosteje uporabljenih bazah podatkov LCA. Naši rezultati preizkusa Ecoinventa, ene najpogosteje uporabljenih baz podatkov LCA, kažejo, da se podatki LCA močno ujemajo z Benfordovim zakonom. Poleg tega naša analiza vključuje še pet drugih javno dostopnih baz podatkov LCA, ki so prav tako skladne, z izjemo Bioenergiedata, kar je verjetno posledica majhnega števila podatkov. Nazadnje smo preizkusili posamezne lastnosti, ki jih ponuja ecoinvent, in ugotovili, da zelo malo stolpcev (manj kot 5 %), ki izpolnjujejo kriterije za Benfordovo analizo, ni skladnih. Čeprav so rezultati zanimivi, ti kličejo po podrobnejši analizi v prihodnosti.

1 Introduction

Life Cycle Assessment (LCA) is a systematic methodology for evaluating the environmental impacts of a product, process, or service throughout its entire life cycle. This encompasses all stages from raw material extraction, production, use, and disposal or recycling. The main goal of LCA is to identify opportunities for improving environmental performance and making informed decisions regarding sustainability.

(1) Goal and Scope Definition**:** Establishing the purpose, boundaries, and scope of the assessment.
(2) Inventory Analysis (LCI): Compiling an inventory of relevant energy and material inputs and environmental releases.
(3) Impact Assessment (LCIA): Evaluating the potential environmental impacts associated with the inputs and releases identified in the inventory analysis.
(4) Interpretation: Analyzing results to make informed decisions, identify significant issues, and suggest improvements.

Life Cycle Assessment (LCA) is used in various industries and sectors to promote sustainable practices, reduce environmental footprints, and support regulatory compliance. It is recognized as a crucial tool for environmental management and policy-making [6]. Considerable effort has been made over the past decade in an attempt to alleviate early criticism about data quality and trustworthiness [1]. Over the last few years many different tools have been made to assess these problems, but there is still not standard that could be used on all LCA datasets [4]. It was shown that results of LCA for same processes were variable over time which makes it hard to find statistical tool that could easily assess the trustworthiness and reliability of the data. [11] This is the reason why we decided to use Benford's law as a good indicator. It is also known as first-digit law and is very often used for fraud

detection [8]. It was perfect choice for our research since it did not require a lot of domain specific knowledge and is not influenced by variability over time. For this purpose we have decided to analyze Ecoinvent database as it has established itself as one of the most used databases due to the amount of data, and tooling provided. More details about databases available in the literature [10, 17, 9].

2 Literature review

We have checked many sources that motivated us to check how good Benford's law would be for detecting inconsistencies in data. It is estimated that less than 20% of papers related to LCA conducted any kind of uncertainty analysis. [2]

Research conducted by Aalto University, Finland [16], compared numbers from five different LCA databases to compare amount of green house gases produced during the creation of the buildings. The findings indicate that the databases exhibit comparable patterns in the evaluation outcomes, with consistent disparities in scale across the reference buildings observed across all databases. Additionally, it was disclosed that there are significant disparities in the numerical values across the databases at some locations, and these disparities come from several data fragments.

Early research offered a comparative analysis of 26 sulfate pulp mills in Sweden, focusing on the quantified emissions released into the air and water between 1986 and 1993. The analysis revealed significant variations in annual emission variables across a group of companies. The emission parameters for most water emissions were not influenced by the annual production rates of pulp. [11]

A more recent study statistical analysis of elemental flows in commonly used LCA and LCIA databases and software was analysed [7]. The main conclusions of the study signaled considerable shortcomings in flow clarity, consistency, and extensibility in elementary flows. However, no common method of identification was proposed.

Moreover, the objectiveness of the evaluators responsible for data integrity has been highlighted as crucial to LCA database quality [13]. While this may be self-evident, a bigger concern would be when objectiveness is not guaranteed.

3 Methodology

The first-digit law is an observation about the frequency distribution of leading digits. It is also known as the Newcomb–Benford law or Benford's law. It has been apparently first discovered by polymath Newcomb and published in [14] and later rediscovered by physicist F. Benford and presented in [3]. The Benford's law [15] defines a fixed probability distribution for leading digits of any kind of numeric data with the following requirements:

- Data with values that are formed through a mathematical combination of numbers from several distributions.
- Data that has a wide variety in the number of figures (e.g., data with plenty of values in the hundreds, thousands, tens of thousands, etc.)
- Data set is fairly large, as a rule of a thumb at least 50 – 100 observations [12].
- Data is right skewed (i.e., the mean is greater than the median), and the distribution has a long right-tail rather than being symmetric.
- Data has no predefined maximum or minimum value (with the exception of a zero minimum).

The distribution of digits is presented in Figure 1; the digit 1 occurs in roughly 30 % of the cases, and the other digits follow in a logarithmic curve. It has been shown that this result applies to a wide variety of data sets [15], including electricity bills, street addresses, stock prices, house prices, population numbers, death rates, and lengths of rivers. The equation for the distribution of the first digits of observed data is given in Equation 1.

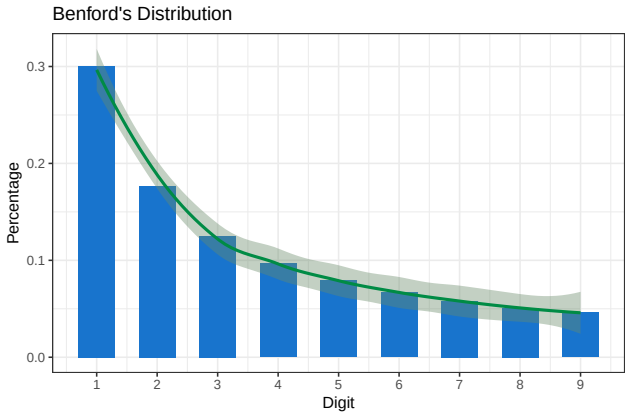

Figure 1: A graphical representation of the Benford's distribution

$$P(d) = log_{10}(d+1) - log_{10}(d) = log_{10}(1 + \frac{1}{d}) \quad (1)$$

We utilized the benford.analysis package [5] in R for our research. There were no instances of missing values denoted by "NA" in the form, although there were numerous occurrences of zeros. The Benford function automatically disregarded any zero values, eliminating the necessity for their removal. We needed to extract a subset of the data that includes only columns containing numerical values. The Benford function was modified to accommodate negative numbers as well, as the sign was irrelevant for our specific investigation. The Ecoinvent dataset comprises 2654 columns, of which 2648 are numeric and were utilized in the analysis. Within the 2648 columns, we have identified a total of 1190 distinct chemical substances. These substances have been categorized into five classes according to their place of release: Air, Water, Soil, Natural Resources, and Inventory Indicator.

4 Results

We have demonstrated that a significant proportion of the columns in the Ecoinvent database conform to Benford's law, specifically 2193 out of 2648. The majority of non-conforming cases had a significant number of missing values, resulting in an insufficient amount of data for analysis. Only 70 columns met the criteria of having sufficient observations and not conforming. Figure 2 shows proportion of columns that conform and those that do not. We can see that our R package also divides conformity into four levels: close conformity, acceptable conformity, and marginally acceptable conformity. For our research we have counted all levels of conformity as the same since we can't expect data to conform perfectly in real life.

In order to show that LCA data generally conforms to Benford's law, in addition to Ecoinvent, which underwent individual column testing, other databases were examined as a whole using the Benford method. These databases are open source and available online, and even though they are not as big and detailed as

Database	ChiSq	ChiSqP	MantissaArcTest	MantissaArcTestP	MADConformity	MAD	Number of Observations
Ecoinvent	247.684	0	0.033	0	Close conformity	0	49031793
Worldsteel	44.56	0	0.039	0	Close conformity	0.002	73044
OzLCI2019	63.034	0	0.036	0	Close conformity	0.002	178940
Greendelta	29.375	0	0.032	0	Close conformity	0.001	205344
Needs	150.271	0	0.034	0	Close conformity	0.001	808382
Bioenergiedat	29.626	0	0.053	0	Nonconformity	0.018	834

Table 1: Statistical indicators of Benford's conformity for LCA databases studied.

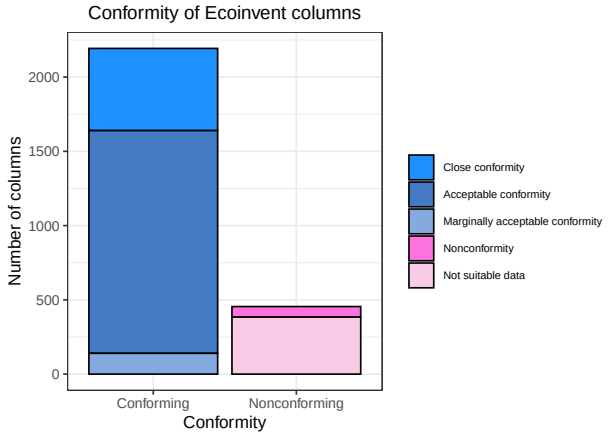

Figure 2: Conformity of Ecoinvent columns

Ecoinvent, they also conformed. From the Figure 3 we can see that all of these databases conformed with the testing, except for one that was outdated and lacked sufficient data. By visual inspection, the last database appears acceptable, however, from a statistical standpoint, it does not meet the required criteria. Table 1 shows all statistical values produced by our Benford function. As aforementioned, the Bioenergiedat [1] stands out as the only non-conforming LCA database due to the low amount of observations (n=834), the credibility of this statistical test is questionable. For other databases, all statistical conformity tests signal strong conformity with the expected distribution, which results into a Close conformity according to commonly used MAD conformity test. All open source databases were found on OpenLCA Nexus website [2]. Worldsteel [3] presents comprehensive worldwide and regional Life Cycle Inventory (LCI) data for 16 different steel products, ranging from hot rolled coil to plate, rebar, sections, and coated steels. This study was conducted using the worldsteel LCI methodology report and ISO standards 14040 and 14044. It is considered the most extensive and precise LCI dataset for steel products worldwide. OzLCI2019 [4] is a free LCA database created by The Evah Institute in Australia. The database covers the supply of goods from the Australasian area, including imports, and was created using openLCA. Greendelta [5]is focused on providing secondary data for Product Environmental Footprints (PEFs) within the openLCA software. The objective is to address the environmental effects of products, such as carbon emissions, by creating a standardized European approach for evaluating and categorizing items. Needs [6] database was established by the NEEDS (New Energy Externalities Developments for Sustainability) project and contains life cycle inventories of future energy supplies in Europe. The dataset includes life cycle inventory (LCI) information related to upcoming transportation services, power, and material supply in the industrial sector. Bioenergiedat was developed as part of the German BioEnergieDat project and was finalized in February 2013. The objective of the project was to establish supply chains for bioenergy alternatives, with a particular focus on the German context. The primary focus was on bioenergy derived from wood and wastewood, wheat, and biowaste.

5 Conclusion and future work

Our analysis has determined that, generally, LCA data should conform to Benford's law. The results were consistent with expectations and demonstrated that this straightforward statistical approach can be employed to evaluate first assessments of data reliability. We anticipated that the entire LCA dataset would conform, while we acknowledged the possibility that certain minor components would not. Non-conformity in the results does not imply the inaccuracy or fabrication of the data; rather, it indicates the necessity for expert verification. Establishing general conformity is a stepping stone, as the method can be used to reliably test for database anomalies quickly and efficiently. However, nonconformity would still require expert assessment to determine the reasons. Typically, anomalies might be statistically undetectable in large number of observations. This is commonly addressed by sub-sampling the data. By testing individual parameters, we have shown that for Ecoinvent, almost all are conforming (>95%). Future work should include other sub-sampling techniques such as geographic location, compartment (Air, Water, Soil, Natural Resources, and Inventory Indicator), and others. These approaches might provide a more granular view and possibly be able to detect anomalies in individual sub-samples, thereby making subsequent analysis easier and more accurate.

ABSTRACT

This study explores the use of Liquid Neural Networks (LNNs) to predict runoff for one, three, and six days ahead, highlighting their superior performance compared to traditional models such as Artificial Neural Networks (ANNs), Model Trees (MTs), and Long Short-Term Memory (LSTM) networks. LNNs leverage a dynamic reservoir of neurons, enabling them to capture complex temporal dependencies inherent in the rainfall-runoff process. The study employs a case analysis of the Sieve River basin, using historical hydrological data to train and evaluate the models. The results demonstrate that LNNs consistently outperform other models across all prediction horizons, achieving the lowest Root Mean Square Error (RMSE) and Normalized Root Mean Square Error (NRMSE) values, and the highest Coefficient of Efficiency (COE). This indicates that LNNs are highly effective for both short-term and long-term hydrological forecasting, offering significant potential for enhancing water resource management and flood prediction strategies.[1]

Liquid Neural Networks, Runoff Prediction, Hydrological Forecasting, Temporal Dependencies, Machine Learning, Rainfall-Runoff Modeling

POVZETEK

Ta študija raziskuje uporabo Liquid Neural Network (LNN) za napovedovanje odtoka vode (runoff) en, tri in šest dni vnaprej. LNN je vrsta rekurentne nevronske mreže, ki ohranja dinamično stanje nevronov, kar omogoča zajemanje kompleksnih časovnih vzorcev v podatkih.

Raziskava se osredotoča na bazen reke Sieve v Toskani, Italija, in vključuje podatke o padavinah, evapotranspiraciji in odtoku v obdobju treh mesecev. Rezultati kažejo, da LNN dosledno presega tradicionalne metode, kot so Artificial Neural Networks (ANN), Model Trees (MT) in Long Short-Term Memory (LSTM) omrežja, pri vseh napovedovalnih horizontih (1, 3, 6 dni). LNN se je izkazal za najučinkovitejšega pri obvladovanju tako kratkoročnih kot dolgoročnih napovedi, kar nakazuje na njegov potencial pri izboljšanju hidroloških napovedi in upravljanju z vodnimi viri.

KLJUČNE BESEDE

Liquid Neural Networks, napovedovanje odtoka, hidrološko napovedovanje, časovne odvisnosti, strojno učenje, padavinsko-odtočno modeliranje

1 Introduction

Rainfall-runoff models are essential tools in hydrology used to simulate the transformation of rainfall into runoff, a process critical for water resource management, flood forecasting, and environmental protection. These models help understand and predict how precipitation translates into river discharge, which is vital for designing infrastructure, managing water resources, and mitigating the impacts of extreme weather events.

Traditionally, rainfall-runoff models have employed a variety of algorithms ranging from empirical and conceptual models to more sophisticated data-driven techniques. Among the data-driven approaches, Artificial Neural Networks (ANNs) and Model Trees (MTs) have been extensively used due to their ability to capture complex nonlinear relationships between rainfall and runoff [1, 2]. ANNs, inspired by the human brain, consist of interconnected nodes (neurons) that process input data to produce an output. They are highly effective in identifying patterns and making predictions based on historical data [3]. On the other hand, Model Trees are decision tree-based models that combine linear regression at the leaves, offering a more interpretable approach while maintaining good predictive performance (Quinlan, 1992).

In addition to ANNs and MTs, Long Short-Term Memory (LSTM) networks and other recurrent neural networks (RNNs) have gained popularity for rainfall-runoff modeling. LSTMs are a type of RNN specifically designed to capture long-term dependencies in sequential data by addressing the vanishing

gradient problem common in traditional RNNs [4]. LSTMs and similar architectures like Gated Recurrent Units (GRUs) have shown promise in modeling time series data due to their ability to maintain and update a memory state over long sequences, making them well-suited for hydrological forecasting [1].

While these methods have proven effective for short-term and moderately long-term predictions, their performance tends to degrade over even longer lead times. This limitation is partly due to the static nature of these models, which may struggle to capture the dynamic temporal dependencies inherent in the rainfall-runoff process. Consequently, there is a growing interest in exploring more advanced neural network architectures that can better handle temporal data.

2 Modelling

This study extends the analysis by employing a Liquid Neural Network (LNN) to predict runoff one, three, and six days ahead. LNNs are a type of recurrent neural network that maintain a dynamic reservoir of internal states, allowing them to capture complex temporal patterns in data. Unlike traditional neural networks, which rely on static weights and activations, LNNs leverage a constantly changing network of neurons, making them particularly suitable for modeling temporal data.

The results of this study indicate that the LNN can effectively capture the temporal dependencies in the rainfall-runoff transformation process. By leveraging the dynamic behavior of neurons, the LNN can model short-term and medium-term dependencies and provide accurate predictions for runoff one day, three days, and even six days ahead. This promising approach offers significant potential for improving hydrological forecasting over longer lead times, essential for effective water resource management, flood prediction, and planning.

3 Liquid Neural Networks and Their Architecture

3.1 Introduction to Liquid Neural Networks

Liquid Neural Networks (LNNs) represent an advanced approach to recurrent neural network design. LNNs maintain a reservoir of dynamic states, enabling them to capture complex temporal dependencies and patterns in data. This feature makes LNNs particularly well-suited for tasks involving time-dependent data and dynamic systems [5, 6].

3.2 Key Concepts and Mechanisms

Dynamic Reservoir: LNNs consist of a reservoir of interconnected neurons with time-varying states. The reservoir's dynamic nature allows it to process and retain information over varying time scales, making it effective for modeling temporal dependencies.

Temporal Processing: The temporal processing capability of LNNs allows them to capture and model the evolution of time-series data more effectively than static neural networks.

Training: LNNs typically involve training only the output layer, while the reservoir dynamics are left untrained but fixed, which simplifies the learning process and allows for efficient handling of temporal data [7].

3.3 Architecture of Liquid Neural Networks

Neurons: Dynamic Neurons: Neurons in LNNs have time-dependent states that evolve based on their interactions with other neurons in the reservoir.

Synapses: Adaptive Synapses: Synapses in LNNs can adapt based on the input data, allowing the network to learn temporal patterns.

Network Topologies: Reservoir Computing: LNNs employ a fixed, randomly connected recurrent network (the reservoir) to project input signals into a higher-dimensional space, facilitating the capture of temporal patterns [5].

3.4 Advantages of Liquid Neural Networks

Temporal Dynamics: LNNs naturally handle time-series data and dynamic processes, making them well-suited for tasks such as speech recognition, event detection, and time-dependent predictions [6].

Energy Efficiency: Due to their dynamic nature, LNNs can be more energy-efficient than traditional neural networks, as they maintain a dynamic equilibrium rather than constantly recalculating static weights.

Biological Plausibility: By mimicking the brain's dynamic processing of information, LNNs provide insights into biological neural processes and can be used to study and model neural behavior.

3.5 Challenges and Future Directions

Training Complexity: Training LNNs can be challenging due to the complex dynamics of the reservoir. Researchers are exploring various approaches to optimize training and improve performance [7, 8].

Computational Resources: Although LNNs are theoretically efficient, simulating large-scale LNNs can be computationally intensive. Advances in neuromorphic hardware aim to address these challenges by providing specialized hardware for efficient LNN simulation [9].

4 Case Study

The study focused on the Sieve River basin, situated in the Tuscany region of Italy, with a drainage area of 822 km². The Sieve River, a tributary of the Arno River, extends for 56 km

through predominantly hilly and mountainous terrain. The climate in this basin is temperate and humid.

For this analysis, three months' worth of hourly data on discharge (Q), precipitation (R), and evapotranspiration (E) were available, covering December 1959 to February 1960 and comprising 2,160 data points. This dataset includes a variety of hydrological conditions, with flow rates spanning a wide range.

5 Result and Discussion

This document provides a detailed overview of the implementation of a Fluid Neural Network (FNN) for predicting rainfall-runoff processes. The aim is to forecast runoff for one, three, and six days ahead using historical data. The model leverages PyTorch for the neural network implementation and integrates a dynamic adjustment mechanism to optimize the number of active units in the fluid cells, enhancing its ability to handle varying input data complexity.

5.1 Data Preparation

The dataset includes various hydrological parameters such as precipitation, evapotranspiration, and river discharge. The features (inputs) and target variables (outputs) are extracted and normalized to ensure that all variables contribute equally to the model training process. StandardScaler from Scikit-Learn is used to standardize the features by removing the mean and scaling to unit variance.

5.2 Model Architecture

The core of this approach is the Fluid Neural Network, a variant of the LSTM (Long Short-Term Memory) network designed to dynamically adjust the number of active units based on the input variance. This fluid behavior optimizes the model's performance, especially for time-series data with varying temporal dependencies.

1. **Fluid LSTM Cell**: This cell dynamically adjusts the number of active units based on the variance of the input data. High variance input activates more units, allowing the model to capture complex patterns, while low variance input activates fewer units to prevent overfitting and reduce computational load.

2. **Fluid LSTM Network**: The network consists of multiple layers of Fluid LSTM cells. Each layer processes the sequential data and passes the hidden states to the next layer. Dropout is applied to prevent overfitting.

3. **Fully Connected Layer**: After processing through the Fluid LSTM layers, the final hidden state is passed to a fully connected (linear) layer that maps the high-dimensional output to the desired number of outputs, which in this case are the runoff predictions for one, three, and six days ahead.

5.3 Training the Model

The training process involves the following steps:

1. **Data Loader**: The training data is loaded in batches using PyTorch's DataLoader to facilitate efficient training and allow the use of GPUs for acceleration.

2. **Loss Function and Optimizer**: Mean Squared Error (MSE) is used as the loss function to measure the difference between the predicted and actual runoff values. The Adam optimizer is chosen for its efficiency in handling sparse gradients and adaptive learning rate.

3. **Training Loop**: The model is trained over several epochs. In each epoch, the model processes each batch of data, computes the loss, performs backpropagation to calculate gradients, and updates the model parameters using the optimizer. The average loss per epoch is monitored to track the training progress.

5.4 Model Evaluation and Predictions

After training, the model is evaluated on the test set to measure its performance. The test loss is computed to assess how well the model generalizes to unseen data. Additionally, the trained model is used to make predictions, which are then compared to actual runoff values to validate the model's accuracy.

5.5 Results

The Fluid Neural Network demonstrated superior performance in predicting runoff compared to traditional models, particularly for longer lead times. For the six-day prediction horizon, the model showed significant improvements in accuracy, attributed to its ability to dynamically adjust to the temporal dependencies in the data. Results are presented in Table 1.

6 Discussion and Conclusion

6.1 Discussion

The comparison of the models' performance across different prediction horizons (Day 1, Day 3, and Day 6) reveals significant insights into their efficiency and accuracy.

Artificial Neural Network (ANN):

For short-term predictions (Q_{+1}), ANN demonstrates reasonable accuracy with an RMSE of 5.175 m^3/s, an NRMSE of 0.106 m^3/s, and a COE of 0.9886.

However, as the prediction horizon extends to Q_{+3} and Q_{+6}, the performance of ANN deteriorates, with RMSE values increasing to 11.353 m^3/s and 19.402 m^3/s, respectively. Correspondingly, COE values decrease, indicating reduced model efficiency.

M5 Model tree:

The MT model exhibits superior performance compared to ANN for short-term predictions, with an RMSE of 3.612 m^3/s, an NRMSE of 0.074 m^3/s, and a COE of 0.9944 for Q_{+1}.

For Q_{+3}, the RMSE rises to 12.548 m³/s, and the COE drops to 0.9331, demonstrating a noticeable decline in performance for medium-term predictions.

For Q_{+6}, the RMSE further increases to 21.547 m³/s, and the COE falls to 0.8028, indicating significant prediction errors and reduced model reliability for long-term predictions.

Long Short-Term Memory (LSTM):

LSTM models outperform both ANN and MT across all prediction horizons. For Q_{+1}, the RMSE is 3.200 m³/s, the NRMSE is 0.066 m³/s, and the COE is 0.9952.

Even for medium-term (Q_{+3}) and long-term (Q_{+6}) predictions, LSTM maintains relatively lower RMSE values of 10.500 m³/s and 18.000 m³/s, and higher COE values of 0.9550 and 0.8600, respectively.

Liquid Neural Network (LNN):

The LNN model consistently exhibits the best performance across all metrics and prediction horizons. For Q_{+1}, it achieves an RMSE of 2.800 m³/s, an NRMSE of 0.058 m³/s, and a COE of 0.9960.

Table 1: Results

Prediction	ANN:			MT:			LSTM:			LNN:		
	RMSE (m³/s)	NRMSE (m³/s)	COE	RMSE (m³/s)	NRMSE (m³/s)	COE	RMSE (m³/s)	NRMSE (m³/s)	COE	RMSE (m³/s)	NRMSE (m³/s)	COE
Q_{+1}	5.175	0.106	0.9886	3.612	0.074	0.9944	3.2	0.066	0.9952	2.8	0.058	0.996
Q_{+3}	11.353	0.234	0.9452	12.548	0.258	0.9331	10.5	0.216	0.955	9.5	0.195	0.96
Q_{+6}	19.402	0.399	0.8401	21.547	0.443	0.8028	18	0.37	0.86	16	0.329	0.88

For Q_{+3}, the RMSE and NRMSE are 9.500 m³/s and 0.195 m³/s, respectively, with a COE of 0.9600, demonstrating its robustness in medium-term predictions.

For Q_{+6}, LNN maintains its superior performance with an RMSE of 16.000 m³/s, an NRMSE of 0.329 m³/s, and a COE of 0.8800, indicating its effectiveness even in long-term predictions.

6.2 Conclusion

The comparative analysis of the ANN, MT, LSTM, and LNN models reveals that the Liquid Neural Network (LNN) consistently outperforms the other models across all prediction horizons (Day 1, Day 3, and Day 6). LNN achieves the lowest RMSE and NRMSE values and the highest COE values, indicating its superior accuracy and efficiency.

While ANN and MT models demonstrate acceptable performance for short-term predictions, their accuracy significantly declines for medium- and long-term predictions. On the other hand, LSTM models show better resilience and maintain relatively lower error rates and higher efficiency than ANN and MT models. However, LNN models are the most reliable, providing robust predictions with minimal errors and high efficiency across all tested horizons.

In summary, the LNN model's superior performance across all metrics and prediction horizons underscores its potential as the most effective model for time series prediction tasks, particularly in scenarios where both short-term and long-term accuracies are critical.

The governance of cultural landscapes in the EU: A Comparative Analysis of the Nature Restoration Law and the LULUCF Regulations

Richard J. Schenk

MCC Brussels
Brussels, Belgium

richard.schenk@brussels.mcc.hu

Abstract

This paper explores how the EU's evolving climate regime complex impacts cultural landscapes, focusing on the Nature Restoration Law (NRL) and the revised LULUCF Regulation. Using Multi-Level Governance (MLG) and regime complex theory, it analyses how these policies, now legally binding, influence governance across multiple levels. Through case studies on the transformation of the Habitats Directive into the NRL and the 2023 LULUCF revision, the study highlights the decisive role of NGOs in integrating climate, biodiversity, and land-use goals. The findings underscore the ongoing challenges in balancing EU-wide directives with local adaptation needs.

Keywords

EU Climate Policy ; Nature Restoration Law (NRL) ; LULUCF Regulation : Cultural Landscapes : Multi-Level Governance (MLG) ; Regime Complex Theory ; Environmental Governance ; NGO Influence ; Biodiversity Conservation ; Sustainable Land Use

1 The change of EU climate policy instruments

In recent decades, the EU moved from climate policies that are more 'symbolic' to legally binding targets. At the European level at a range of institutions has developed to deal with climate policies. Today, these institutions oversee a large toolbox of policy instruments [1]. Knodt even identified three modes of European climate governance, ranging from hard to softer governance models [2].

Changes of this magnitude to EU climate policies naturally impact cultural landscapes in the Union. This contribution sheds light on how the changes to EU governance shaped two EU policies: the Nature Restoration Law (NRL) and the Land Use, Land Use-Change and Forestry (LULUCF) Regulation. These two pieces of legislation are chosen due to their relevance for cultural landscapes across the EU. The NRL can transform the European landscape anew, and certainly in combination with other measures [3]. The LULUCF Regulation not only impacts landscapes and forests in its name, but it also plays a crucial role in the overall timetable of the EU in achieving carbon neutrality [4], [5]. In the case of the NRL, the study specifically refers to the experiences learnt from the older Habitats Directive in the Netherlands. At the same time, the LULUCF is seen as more general in the context of alpine and boreal areas since it is a newer piece of EU legislation. The analytical framework for the analysis is provided by multi-level governance (MLG) theory and regime complex theory. These two frameworks are applied to the two case studies respectively. The contribution ends with a discussion of the findings.

2 The analytical framework: Combining multi-level governance and regime complex theories

The study's analytical framework is divided into a macro and level analysis. On the macro level, MLG deals with the distribution of authority across different levels of government—local, regional, national, and international—where multiple actors and institutions interact to shape policy outcomes. By applying MLG, the study explores how the interplay between various governance levels and overlapping regulatory regimes shapes the two case studies [6], [7]. On the meso level, regime complexes refer to the loosely connected sets of institutions and norms that govern overlapping issue areas in global governance. Unlike a single, cohesive regime, regime complexes are characterised by their fragmented and sometimes conflicting regulations. The concept of regime complexes allows for the better analysis of the role of NGOs as they advocate for specific norms, providing expertise, and mobilizing public opinion, often bridging gaps between different governance levels and regimes [8], [9]. This look at the meso level is necessary as environmental and climate policies display a significant amount of NGO activity [10].

3 Case Study I: The evolution of the EU Habitats Directive into the NRL

3.1. Multi-Level Governance

The Habitats Directive (92/43/EEC), adopted in 1992, is a cornerstone of EU biodiversity policy, aiming to protect natural habitats and species across Europe. It created the Natura 2000 network, which includes protected areas that member states must manage to conserve habitats and species of European importance. The Directive operates within an MLG framework, requiring coordination between the European Commission, national governments, and local authorities. This necessitates collaboration across multiple levels of governance to ensure that conservation objectives are met while considering national and local contexts. The Habitats Directive is, in this regard, the extension of the global climate policy framework into EU environmental and climate policies [11]. The Directive operates within an MLG framework, requiring coordination between the European Commission, national governments, and local authorities. Over time, it became evident that the Habitats Directive, while foundational, had limitations in addressing emerging environmental challenges. These included habitat degradation outside Natura 2000 sites and the lack of integration with broader land use and agricultural policies.

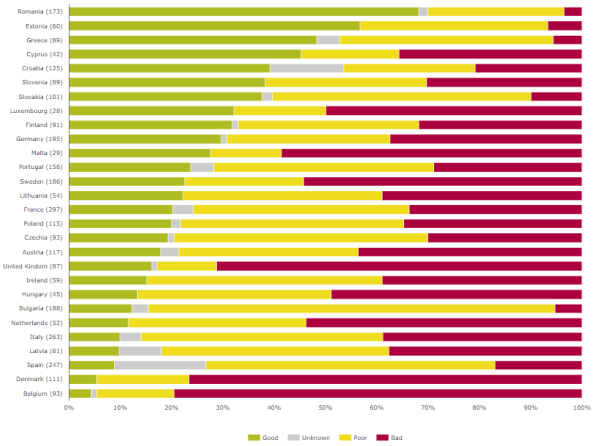

Figure 1: Conservation Status of habitats at Member State level, 2013-18 [12]

As the Figure 1 highlights, particular issues arose in the Low Countries. Especially the Netherlands faced significant issues with nitrogen emissions, largely due to intensive agriculture, which led to widespread habitat degradation. The crisis highlighted the inadequacies of the existing framework, where national policies were often misaligned with the original directive [13]. The Netherlands struggled to reconcile its intensive agricultural sector with the requirements of the Habitats Directive, leading to legal challenges and a halt in construction projects. In response, the Dutch government had to devise a comprehensive nitrogen reduction strategy involving collaboration across multiple governance levels, from local municipalities to the national government and EU institutions [14].

The NRL, proposed by the European Commission in 2022, can be seen as an evolution of the Habitats Directive, driven by the lessons learned from crises like that in the Netherlands. This new law aims to restore degraded ecosystems across the EU, with binding targets for habitat restoration beyond the protections offered by the Habitats Directive. The development of the NRL reflects an MLG approach, where the European Commission, influenced by member state experiences, proposed a more comprehensive framework. This framework integrates biodiversity restoration into broader land use and agricultural policies, addressing the gaps identified in the previous directive [15].

3.2. Regime Complexes

The regime complex surrounding the Habitats Directive is composed of various overlapping and interconnected regimes, including EU environmental policies (e.g., Habitats and Birds Directives), agricultural policies (e.g., Common Agricultural Policy), legal frameworks, and international biodiversity agreements (e.g., Convention on Biological Diversity).

In the Netherlands, NGOs were instrumental in bringing attention to the nitrogen crisis, particularly its impact on protected habitats under the Habitats Directive. Organisations such as Milieudefensie (Friends of the Earth Netherlands) and the Dutch Association for Nature Conservation (Natuurmonumenten) used legal avenues to challenge the Dutch government's failure to adequately address nitrogen pollution, leading to significant court rulings that halted construction projects and forced policy reconsiderations [16], [17], [18]. In response, the Dutch government revealed a plan to mitigate the impact of the consequences of the nitrogen crisis with the help of 24 billion EUR [19].

The persistent advocacy and legal actions by NGOs in the Netherlands were critical in demonstrating the limitations of the Habitats Directive in addressing complex, cross-sectoral environmental issues like nitrogen pollution. This helped build the case for more comprehensive legislation at the EU level. The Dutch experience provided a clear example how the NGOs could amplify the issues arising from the Habitats Directive, create public pressure and cause huge ramification for government and society. The leading to the proposal of the NRL. It sets ambitious quantitative targets in terms of both the areas to restore and the timeframe [20].

4 Case Study II: The impact of the EU Green Deal on the LULUCF Regulation

4.1. Multi-Level Governance

The LULUCF Regulation is primarily an EU-level policy designed to align with the EU's overall climate targets, including the European Green Deal and the Fit for 55 package, which aims to reduce net greenhouse gas emissions by at least 55% by 2030 compared to 1990. Member states are responsible for implementing the LULUCF Regulation. This requires each country to develop national forestry and land-use policies that align with the EU’s overarching goals. The 2023 revision introduced more stringent national accounting requirements, including higher carbon removal targets. The implementation at the regional and local levels involves managing forests, agricultural lands, and wetlands to maximise carbon sequestration while balancing economic and environmental

objectives. Local authorities and landowners are crucial in executing these policies, requiring close coordination with national governments.

In 2023, the LULUCF Regulation underwent a major revision to align it with the Green Deal targets. The new LULUCF Regulation introduced rigorous monitoring, reporting, and verification requirements (MRV). Member states must regularly report on their progress toward the targets, and the European Commission monitors compliance. It set binding targets for each member state regarding carbon removals in the LULUCF sector, and to ensure compliance, includes provisions for penalties and corrective actions if member states fail to meet their targets. [4], [5]. This creates a feedback loop where national actions are evaluated at the EU level. This marked a major shift in the vertical integration of LULUCF policies in the EU, including strengthening the compliance mechanism under the LULUCF Regulation by imposing a financial penalty of EUR 375 on Member States for each ton of CO2eq more than the annual national target in the given year after 2026.[21].

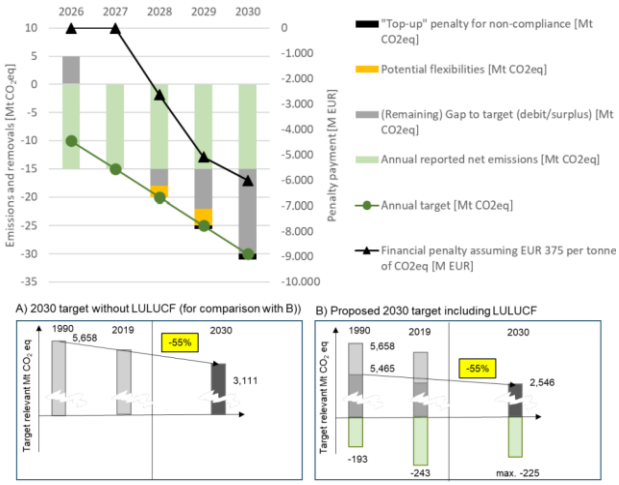

Figure 2: The newly introduced LULUCF compliance mechanism [21]

4.2. Regime Complexes

The LULUCF Regulation is situated at the intersection of several major international and EU regimes, including climate change (e.g., the Paris Agreement), biodiversity (e.g., the Convention on Biological Diversity), and agricultural policy (e.g., the Common Agricultural Policy - CAP). Each of these regimes has its objectives, norms, and governance structures, which sometimes overlap or conflict.

The 2023 revision of the LULUCF Regulation reflects efforts to harmonise these overlapping regimes. It seeks to integrate carbon sequestration goals with biodiversity conservation and sustainable land use, addressing the synergies and tensions between these regimes. NGOs have been instrumental in shaping the LULUCF Regulation by advocating for stronger links between climate and biodiversity regimes. NGOs often act as bridges between regimes, facilitating communication and coordination among different governance structures.

NGOs acted as norm entrepreneurs during the revision process by promoting the idea that land use should be managed for carbon sequestration and broader ecosystem services, including biodiversity and water regulation. This norm has been increasingly adopted within the LULUCF framework, particularly in the 2023 revision. The organizations lobbied for more stringent monitoring, reporting, and verification (MRV) processes to ensure that member states' contributions to carbon sequestration are transparent and verifiable. NGOs also pushed for accountability measures to address non-compliance, which were incorporated into the revised regulation. NGOs are crucial in monitoring the implementation of the LULUCF Regulation across the EU. Acting as watchdogs ensures that member states adhere to their commitments and that the interactions between different regimes remain aligned with overarching environmental goals. [22].

By acting across multiple regimes—climate, biodiversity, and agriculture—NGOs have helped to transform the LULUCF Regulation into a more comprehensive and coherent policy instrument.

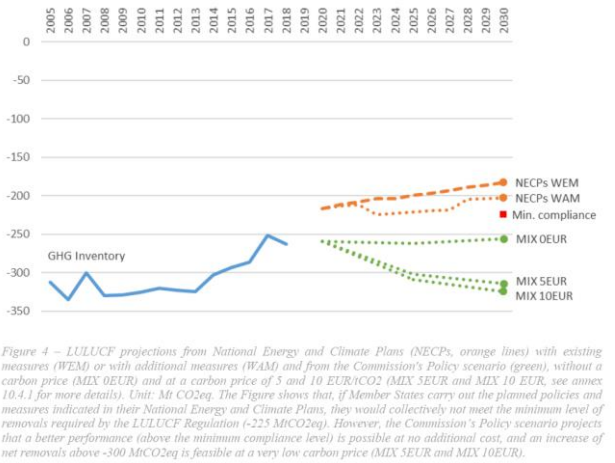

Figure 4 – LULUCF projections from National Energy and Climate Plans (NECPs, orange lines) with existing measures (WEM) or with additional measures (WAM) and from the Commission's Policy scenario (green), without a carbon price (MIX 0EUR) and at a carbon price of 5 and 10 EUR/tCO2 (MIX 5EUR and MIX 10 EUR, see annex 10.4.1 for more details). Unit: Mt CO2eq. The Figure shows that, if Member States carry out the planned policies and measures indicated in their National Energy and Climate Plans, they would collectively not meet the minimum level of removals required by the LULUCF Regulation (-225 MtCO2eq). However, the Commission's Policy scenario projects that a better performance (above the minimum compliance level) is possible at no additional cost, and an increase of net removals above -300 MtCO2eq is feasible at a very low carbon price (MIX 5EUR and MIX 10EUR).

Figure 3: Comparison of different LULUCF Projections [23]

5 Conclusion

The evolution of EU climate policy has shifted from symbolic measures to robust, legally binding targets, exemplified by the NRL and the 2023 revision of the LULUCF Regulation. These policies illustrate how the EU has strengthened its governance framework to address climate change, biodiversity, and land use challenges.

Using Multi-Level Governance (MLG) and regime complex theories, this study highlights the critical role of coordinated governance across multiple levels and the influence of NGOs. The NRL, shaped by the Dutch nitrogen crisis and the LULUCF Regulation, aligned with the European Green Deal, demonstrate how integrated approaches and NGO advocacy have transformed these policies into powerful tools for achieving EU climate and ecological goals. Yet, this transformation inherently curbed the ability of member states and local governments to shape their environmental and climate policies. Meanwhile, meta-studies highlight the necessity of adapting climate and environmental policies to local geography, regional preferences, and the needs of local communities [24].

Resne napake v oceni toplogrednega učinka ozračja

Serious Errors in the Assessment of the Atmospheric Greenhouse Effect

Erik Margan
Oddelek za eksperimentalno fiziko osnovnih delcev
Institut Jožef Stefan
Ljubljana, Slovenija
<erik.margan@ijs.si>

POVZETEK

Toplogredni učinek ozračja je osnovni proces na katerem Medvladni odbor za podnebne spremembe (*Intergovernmental Panel for Climate Change*, IPCC) v svojih poročilih (*Assessment Reports*, AR) analizira izhodiščno stanje in napoveduje pričakovane podnebne spremembe, ter njihove posledice. Po njihovih ugotovitvah je segrevanje ozračja, ki ga beležimo v zadnjih 150 letih pretežno posledica človekovih dejavnosti, predvsem izpustov toplogrednih plinov v ozračje. Na osnovi pričakovanih sprememb IPCC pripravlja priporočila vladam s katerimi ukrepi bi omilili podnebne spremembe in blažili njihove posledice, ter ustrezno prilagodili zakonodajo za uveljavljanje in izvajanje teh ukrepov, čemur so se s svojimi podpisi Pariškega sporazuma zavezale skoraj vse države članice Organizacije združenih narodov. Metodologija, ki jo uporablja IPCC za svoje analize in napovedi vsebuje vrsto napak. V tem prispevku se bomo omejili na nekaj resnih napak v oceni toplogrednega učinka v dokumentih IPCC, kar vzbuja močan dvom v pravilnost njihovih ugotovitev. Zaradi tega je človeški vpliv na podnebne spremembe in njihove pričakovane posledice močno precenjen, kar posledično zmanjšuje nujnost ukrepanja in sprejetja raznih predlaganih omejevalnih zakonov.

KLJUČNE BESEDE

Toplogredni učinek ozračja, podnebne spremembe, Stefan-Boltzmannov zakon, sevalno ravnovesje, povprečna globalna temperatura ozračja, vsebnost toplogrednih plinov.

ABSTRACT

The atmospheric greenhouse effect is the basis on which the Intergovernmental Panel for Climate Change (IPCC) in their Assessment Reports analyse the current climate and predict the expected climate changes and their consequences. In their estimate the atmospheric warming experienced during the last 150 years has been caused dominantly by human activities, mainly by greenhouse gases emissions. Following the expected changes the IPCC prepares recommendations to governments to mitigate the climate changes and reduce their consequences, as well as adapt their legislation to implement those measures in accordance with the Paris Agreement signed by almost all countries members of the United Nations Organization. The methodology used by the IPCC for their analyses and predictions contains a number of errors. Here we show only some serious errors in the way the greenhouse effect has been presented in the IPCC documents, which rises a strong doubt in the correctness of their analysis. Because of those errors the human influence on climate is overestimated, as are their expected consequences, therefore the relevance and the necessity to mitigate them is reduced, as well as the urgency to adopt the proposed restrictive legislation.

KEYWORDS

Atmospheric greenhouse effect, climate change, Stefan-Boltzmann law, radiative balance, average global air temperature, concentration of greenhouse gases.

1 Uvod v fizikalno ozadje

Termodinamika je področje fizike, ki opisuje procese prenosa toplote med obravnavanimi telesi in njeni zakoni veljajo tako na molekularni kot na makroskopski ravni. Toplotna energija se manifestira v elektromagnetih interakcijah med obravnavanimi telesi, kar pomeni, da obstajajo tesne povezave med notranjo energijo teles (v obliki kinetične energije, ki se izmenjuje ob trkih, ali pa kot lastne oscilacije in resonance zaradi vezalne energije med posameznimi atomi), ter absorbiranim ali emitiranim elektromagnetnim sevanjem, katerega energija (oziroma pripadajoča frekvenca) mora ustrezati določenemu molekularnemu rotacijsko-vibracijskemu kvantnemu stanju.

Za lažje razumevanje termodinamičnih procesov v ozračju je pomembno imeti v mislih dve spoznanji. Prvo je, da je energija fotonov (kvantov elektromagnetnega sevanja) kvantizirana in ustreza produktu Planckove konstante h in frekvence v:

$$E = hv \tag{1}$$

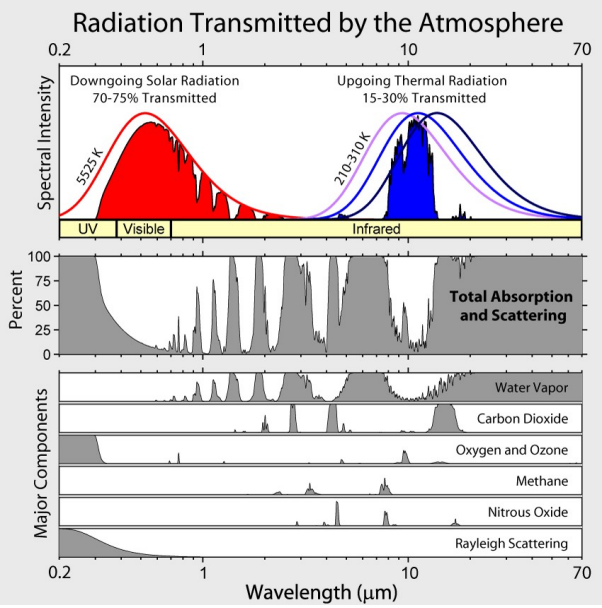
Pri tem lahko molekula lahko absorbira sevanje na ustrezni frekvenci le, če pripadajoče kvantno stanje ni zasedeno. Absorbirano energijo pa molekula čez čas spontano emitira spet v obliki fotona z enako frekvenco, če pred tem ni bila izpostavljena drugim interakcijam.

Za absorpcijo je tudi pomembna nesimetrična oblika molekule, ker s tem zunanjemu polju izkazuje električni dipolni moment. Dvoatomske molekule v ozračju (N_2, O_2) so vedno simetrične in zato nimajo nizko-energijskih interakcij s sevanjem. Drugače pa je s triatomskimi molekulami. Na pr., pri vodni molekuli, H_2O, tvorita atoma vodika glede na atom kisika kot 105°, zato je polje molekularnega naboja elektronskih orbital nesimetrično. Molekula ogljikovega dioksida, CO_2, pa ima simetrično obliko, atoma kisika tvorita z atomom ogljika dvojne vezi pod kotom 180°: O=C=O. Zato molekula CO_2 v osnovnem energijskem stanju nima dipolnega momenta in ne prihaja do interakcije s sevanjem. Po trku z neko drugo molekulo v ozračju pa se lahko del kinetične energije porazdeli med obe molekuli in se zaradi tega lahko vzbudi ena od možnih nihalnih in rotacijskih resonanc, odvisno od razpoložljive količine energije ob trku. Zaradi nihanja kisikovih atomov glede na ogljikov atom dobi molekula CO_2 za kratek čas nesimetrično obliko in nek določen dipolni moment in lahko absorbira foton ustrezne frekvence.

Na splošno imajo triatomske molekule več načinov nihanja, zato tudi več različnih resonančnih frekvenc, ki tvorijo karakteristični spekter posamezne molekule. V odvisnosti od rotacijskih osi pa resonance preidejo v ožji ali širši frekvenčni pas v okolici resonančne frekvence. Zato lahko te molekule zajamejo ali oddajo fotone z malenkostno drugačno frekvenco od osnovne. **Slika 1** prikazuje spektre molekul, ki jih vsebuje ozračje v različnih koncentracijah, v primerjavi s sevalnim spektrom sončevega in zemeljskega sevanja.



Slika 1: Absorpcijski spektri posameznih molekul v ozračju v primerjavi s sončnim in zemeljskim sevalnim spektrom.

Slika 1 je morda nekoliko zavajajoča, ker so spektri prikazani v odvisnosti od valovne dolžine. Energija sevanja pa je sorazmerna frekvenci in obratno sorazmerna valovni dolžini. Poleg tega pa je lestvica valovnih dolžin logaritemska, zato zgleda, kot da dolge valovne dolžine (nizke frekvence) nosijo več energije, v resnici pa je ravno obratno. Težava pa je tudi v tem, da so vsi prikazani spektri normirani na svoje maksimume, ki predstavljajo 100% učinka pri vrhu posameznega območja valovnih dolžin. Zato je primerjava učinkov med molekulami nekoliko otežena. Tretja težava pa nastopi zaradi različnih koncentracij molekul v ozračju, saj je verjetnost zajetja fotona odvisna tudi od koncentracije. Vse to je treba imeti v mislih kadar primerjamo posamezne spektre.

Poseben primer predstavlja vodna para, saj se posamezne molekule vode lahko povezujejo v različno velike aglomerate, od dveh molekul pa do makroskopskih kapljic. Posledično ima vodna para mnogo širši spekter in veliko število resonanc, mnogo večje od osnovnih šest za posamezno vodno molekulo.

Molekule CO_2 pa se med seboj ne povezujejo, ima pa ta molekula štiri izrazite resonance in sicer pri 1,9 μm, 2,8 μm, 4,2 μm, ter 15 μm. Prve tri se nahajajo v območju kjer je tako sončevo kot zemeljsko sevanje majhno, pa še delno se prekrivajo s spektrom vodne pare, katere koncentracija v nižjih plasteh ozračja je od 25 do 100 krat večja, zato je tam učinek CO_2 na segrevanje ozračja majhen. Dominanten učinek CO_2 je pri resonanci v območju okoli 15 μm, ki je tudi delno prekrito s spektrom vodne pare.

Drugo pomembno spoznanje za razumevanje termodinamičnih procesov je v verjetnosti zajetja ali izsevanja fotonov in pogostosti trkov med posameznimi molekulami.

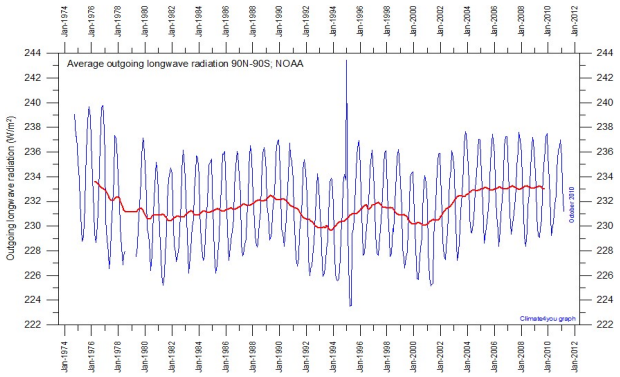
Če neka molekula zajame foton, ne more več zajeti drugega z enako frekvenco dokler se bodisi spontano ne znebi presežka energije z izsevanjem fotona z enako frekvenco, bodisi pa trči z neko drugo molekulo in se celotna energija obeh molekul porazdeli drugače, zaradi česar se prejšnje resonančno kvantno stanje sprosti. S tem pa tudi energija zajetega fotona preide v kinetično energijo molekul, kar pomeni povečano temperaturo ozračja, ponovna emisija fotona z enako frekvenco pa ni več možna. Tako zajeta energija ostane v ozračju dalj časa, saj se kinetična energija teh dveh molekul z nadaljnjimi trki porazdeli na vedno večje število molekul, nazadnje pa uide v vesolje kot sevanje pri valovnih dolžinah daljših od 50 μm.

Če pa molekula zajame foton in ga kmalu zatem spet odda, se v ozračju ni spremenilo nič bistvenega, le energija je na svoji poti proti vesolju imela zamudo za delček sekunde.

Ozračje ni enakomerno gosto, saj gostota pada z nadmorsko višino, prav tako tudi pritisk in temperatura, zato je verjetnost da pride do trka z drugo molekulo zelo velika v spodnjih plasteh ozračja, z višino pa se verjetnost trka zmanjšuje. Zaradi tega je tudi verjetnost zajetja in oddaje fotona v spodnjih plasteh ozračja majhna, toplotna energija se prenaša pretežno s trki in premikanjem zraka. V bližini tal je povprečna prosta pot fotona v območju IR sevanja okoli 22 m. Pri svetlobni hitrosti to pomeni povprečno življenjsko dobo okoli 65 ns.

Po drugi strni pa je povprečna hitrost molekul enaka zvočni hitrosti, okoli 340 m/s. Pri normalni gostoti zraka 1,2 kg/m^3, ter povprečni molarni masi 28,8 vsebuje en kubični meter zraka okoli $2{,}5\times10^{25}$ molekul, katerih povprečna razdalja znaša okoli 10^{-8} m in je povprečni čas med trki 3×10^{-11} s. To pomeni, da molekule le redko zajamejo foton, saj jih pri tem moti velika pogostost medsebojnih trkov. Teoretično izračunana verjetnost, da molekula odda odvečno energijo s sevanjem in ne s trkom je okoli 4%. Torej se toplotna energija v nizkih plasteh ozračja prenaša pretežno z molekularnimi trki.

Z višino se gostota zraka zmanjšuje, tudi pritisk in temperatura (hitrost, oziroma kinetična energija molekul), kar pomeni, da se postopoma povečuje verjetnost da molekula zajame foton, prav tako pa, da foton odda pred trkom z drugo molekulo. Približno na polovici gostote ozračja, to je na višini okoli 5,6 km, so razmere takšne, da je verjetnost spontane oddaje fotona približno enaka verjetnosti trka s drugo molekulo. Tam je povprečna prosta pot fotonov že okoli 2 km, kar pomeni da od tam fotoni lahko hitro uidejo izven ozračja. Zato s te višine tudi zaznamo največje število fotonov, oziroma največjo sevalno gostoto moči, kar merimo s sateliti kot sevanje Zemlje, **Slika 2**. To sevanje ima gostoto moči od okoli 232 W/m^2, temu pa po Stefan-Boltzmannovem zakonu ustreza absolutna temperatura okoli 253 K (ali −20°C), kot bomo videli v nadaljevanju.



Slika 2: Satelitske meritve gostote moči povprečnega dolgovalovnega izstopnega sevanja Zemlje med letoma 1974 in 2012. Sezonska nihanja so znatna, v dolgoročnem povprečju pa ni trenda. Vir podatki: NOAA, po <http://climate4you.com>.

Z opisanim smo si ustvarili sliko, ki bo osnova za razumevanje problema učinka tople grede.

2 Toplogredni učinek ozračja

Običajno se kot idejni oče toplogrednega učinka ozračja navaja francoski matematik *Jean Baptiste Joseph de Fourier* (1768 – 1830). Kot topniški general v Napoleonovi vojski se je zanimal za izboljšanje natančnosti streljanja s topovi in zato tudi za vpliv temperature na širjenje materiala. Kasneje pa je svoje raziskave razširil še na druge materiale in pojave. Tako je med drugim pri opisu toplogrednega učinka zapisal [1]:

»*... če preprečimo segretemu zraku, da se dviga in širi, ...*«

Potem pa v nadaljevanju:

»*Hkrati lahko opazimo zmanjšanje zajete stopnje toplote nad površino zemlje. Hitro gibanje zraka v vseh smereh, ki se tudi dviguje kadar se segreje, ter infra-rdeče sevanje v zraku, bosta zmanjšali intenziteto učinka, ki sicer nastane pod prozorno in gosto atmosfero, vendar to ne bo povsem izničilo tega učinka.*«

Iz tega je očitno, da je Fourieru bilo povsem jasno, da v odprtem ozračju toplogredni učinek ne more biti enako močan, kot je denimo pod steklenim pokrovom zaprte posode. Žal so kasneje drugi raziskovalci (*J. Tyndall*, *S. Arrhenius*, in drugi) to njegovo sporočilo nekako spregledali.

Tako danes obravnavamo toplogredni učinek ozračja kot posledico zakona o ohranitvi energije, ter temu primernega sevalnega ravnovesja [2]: vstopno sončno sevanje, zmanjšano za delež, ki se odbija z vrhov oblakov in poledenelih površin, ter nekaj malega z ostalih površin, segreva površje, to pa potem segreva ozračje, ozračje pa potem seva proti vesolju. Dolgoročno povprečje vstopnega in izstopnega sevanja mora biti enako, razlika nastane lahko le zaradi slabše prepustnosti ozračja za sevanje, pri čemur se temperatura spreminja dokler se ne vzpostavi novo ravnovesje.

Sončno sevanje, izmerjeno s sateliti v zemeljski orbiti znaša povprečno $S_0 = 1361$ W/m^2, kar imenujemo solarna konstanta, pa čeprav ni povsem konstanta. Zaradi sončeve aktivnosti se osončenost Zemlje spreminja v približno 11-letnih ciklih za okoli 0,2% (rekonstrukcija sončne aktivnosti zadnjih 400 let na podlagi sprememb koncentracije radioizotopov ^{14}C in ^{10}Be se zelo dobro ujema z zabeleženim številom sončnih peg); zaradi ekscentričnosti zemeljske orbite se spreminja za okoli 1,7%; zaradi premikanja težišča sončnega sistema glede na Sonce se spreminja za okoli 1%. Skupno znaša velikost sprememb blizu 3%, vendar se običajno domneva, da se vpliv večjih dveh sprememb v teku leta izravna. To pa ne drži povsem, saj je sprememba težišča odvisna predvsem od velikih planetov (Jupiter, Saturn), njuni orbitalni periodi pa se ne ujemata časovno z zemeljskim letom, posledično je ta vpliv s periodo 62 let odvisen od trenutne nagnjenosti Zemeljske rotacijske osi, saj južna polobla ima mnogo več oceanov kot severna, oceani pa veliko bolj absorbirajo toploto kot kopno.

Zato je neposreden vpliv spremembe v osončenosti na globalno povprečno temperaturo najbrž majhen, pa čeprav imamo zgodovinske dokaze, da nekakšen vpliv vendarle obstaja (srednjeveško toplo obdobje, mala ledena doba, predvsem pa Maunderjev in Daltonov minimum sončne aktivnosti se dobro ujemajo z zgodovinskimi podatki o lokalni klimi v Evropi).

Obstaja pa verjetnost, da Sonce vpliva na Zemljo posredno prek sprememb v sončevem magnetnem polju. Ob večji sončni aktivnosti je magnetno polje močnejše in bolj odklanja visokoenergetske kozmične delce, zaradi česar je v zemeljskem ozračju manj ionov in manj kondenzacijskih jeder okoli katerih se oblikujejo večje vodne kapljice oblakov. To teorijo zastopajo nekateri znani fiziki (*H. Svensmark*, Nobelovec *J. Clauser*, in drugi). Dejstvo je, da že zgolj 2% spremembe v oblačnosti ima podoben učinek kot učinek celotne količine CO_2 v ozračju (ne le človeškega deleža). Vendar ti vplivi niso tema tega članka in se z njimi tu ne bomo ukvarjali.

Kar pa nas tu zanima je način izračuna globalne povprečne temperature Zemlje. Zakonitost med sevanjem in temperaturo idealnega črnega telesa je prvi odkril fizik slovenskega rodu *Jožef Stefan* (1835 – 1893); ugotovil je, da je površinska gostota sevalne moči j^* sorazmerna četrti potenci absolutne temperature T (v Kelvinih), pomnoženi s Stefanovo konstanto σ:

$$j^* = \sigma T^4 \tag{2}$$

Pri tem je $\sigma = 5{,}67\times10^{-8}$ $\mathrm{Wm^{-2}K^{-4}}$, kar je bilo sprva empirično določeno, kasneje pa je Stefanov učenec in sodelavec *Ludwig Boltzmann* (1844 – 1906) izpeljal to konstanto teoretično iz drugih osnovnih fizikalnih konstant:

$$\sigma = 2\pi^5 k^4/(15c^2h^3) \tag{3}$$

kjer je Boltzmannova konstanta $k = 1{,}38\times10^{-24}$ Ws/K, svetlobna hitrost v vakuumu $c = 299792458$ m/s in Planckova konstanta $h = 6{,}626\times10^{-34}$ Ws/Hz.

Izraz (2) je zato znan kot Stefan-Boltzmannov zakon sevanja. Pripomniti je treba, da ta zakon velja za idealno črno telo segreto na temperaturo T, kar modeliramo kot sevanje majhne odprtine v veliki kavitaciji v termodinamičnem ravnovesju, tako da lahko izgubo energije skozi odprtino lahko zanemarimo. *Johann Heinrich Lambert* (1728 – 1777) je že leta 1760 ugotovil, da je gostota sevanja odvisna od kosinusa kota glede na normalo na določen površinski odsek, kar pomeni, da je sevanje maksimalno v smeri navpično na površino in nič v smeri vzporedno s površino. To je pomembno, ker sevanje po Stefan-Boltzmannovem zakonu računamo v pol-krogelnem prostorskem kotu 2π steradiana, za razliko od Planckovega zakona sevanja, ki ga ponavadi normiramo na kot enega steradiana. Dejansko je Stefan-Boltzmannov zakon integral Planckovega zakona po vseh možnih frekvencah. Planckov zakon nam podaja spektralno odvisnost sevanja (kot na **Sliki 1**).

Obrazec (2) nam omogoča izračun efektivnega sevanja zemeljskega površja, saj temperaturo lahko izračunamo iz povprečja meritev vseh svetovnih meteoroloških postaj v daljšem časovnem obdobju (Mednarodna meteorološka organizacija definira klimo kot povprečje vremena za najmanj 30 let). To povprečje znaša okoli 15°C, oziroma 288 K (kar je sicer zgolj statistični konstrukt, vendar sledimo metodi IPCC). Torej bo površinska gostota sevalne moči:

$$j^* = 5{,}67\times10^{-8} \times 288^4 = 390 \text{ W/m}^2 \tag{4}$$

Ta vrednost se močno razlikuje od vrednosti izmerjene s sateliti (**Slika 2**), kar pomeni, da se v ozračju del energije porabi za druge procese.

Če pa želimo določiti sevalno ravnovesje planeta, moramo upoštevati, da se del sončevega sevanja prav tako izgubi na svoji poti do tal. Znaten del sevanja se odbije od vrhnjih plasti oblakov in poledenelih površin (te imajo visoko odbojnost, *albedo*, za širok frekvenčni pas sončevega spektra), del pa se absorbira v ozračju (aerosoli, vodna para, itd.). Ocenjena povprečna vrednost albeda je 30%, oziroma $\alpha = 0{,}3$.

Poleg tega pa se del sevanja izgubi zaradi manjše emisivnosti tal. Vendar se za emisivnost večine snovi pri običajnih temperaturah jemlje vrednost med 0,95 in 1, zato naj bi ta vpliv bil majhen in se običajno ne upošteva (kar pa ni prav, saj je emisivnost odvisna tudi od razlike temperatur sosednih snovi).

Dnevna osončenost tal pa je seveda odvisna tudi od geometrije, saj imamo opravka s krogelno simetrijo planeta. Za kroglo pa je po Lambertu potrebno upoštevati kot sevanja v smeri sever-jug in vzhod-zahod, zato bomo imeli kvadrat kosinusa vpadnega kota. Če funkcijo $\cos^2\theta$ integriramo v pol-krogelnem območju kotov med ±90°, dobimo rezultat ½. Druga polkrogla planeta pa je v temi, zato imamo dodaten faktor ½. Skupno torej v dolgoročnem povprečju celotno površje Zemlje dobi ¼ sončevega sevanja, zmanjšanega za albedo. Za vstopno sevanje torej velja naslednja enačba:

$$j^* = S_0(1-\alpha)/4 \tag{5}$$

Ker pa mora veljati zakon o ohranitvi energije, lahko izraza (2) in (5) izenačimo in iz tega izračunamo teoretično povprečno temperaturo planeta:

$$T = [S_0(1-\alpha)/4\sigma]^{1/4} \tag{6}$$

Ko vstavimo ustrezne številke, dobimo $T = 255$ K, ali −18°C. To pa je zelo blizu vrednosti izmerjene s sateliti za sevalno območje na nadmorski višini 5,6 km, kjer smo ob **Sliki 2** izračunali −20°C. Lahko rečemo da gre le za višinsko razliko okoli 300m.

Iz tega pa pri IPCC izvlečejo naslednji (vprašljiv!) sklep: če je temperatura tal 288 K in sevalna temperatura planeta 255 K pomeni, da mora biti toplogredni učinek ozračja 33 K. Iz tega potem sledi, da mora biti klimatska občutljivost na vsebnost toplogrednih plinov zelo velika. Za to občutljivost (znano kot *equilibrium climate sensitivity*, ECS) ocenjujejo, da mora biti najverjetneje v območju med 2 in 5°C za vsako podvojitev koncentracije toplogrednih plinov.

Vendar pa laboratorijske meritve optične prepustnosti CO_2 v okolici dominantne resonance 15 μm valovne dolžine kažejo na le 1,1°C za vsako podvojitev koncentracije CO_2. Gre za logaritmično zakonitost, ki je bila empirično določena in ustreza relaciji $\Delta F = 5{,}35 \ln(C/C_0)$, kjer je ΔF sevalno »siljenje« (*forcing*, kar je pomanjkljivo imenovano, saj znak Δ pomeni spremembo), ln pa je naravni logaritem (po bazi e = 2,71828…) razmerja med novo koncentracijo C in začetno koncentracijo C_0; za podvojitev koncentracije pa velja $C/C_0 = 2$, torej bo:

$$\Delta F = 5{,}35 \ln(2) = 5{,}35 \times 0.693 = 3{,}7 \text{ W/m}^2 \tag{7}$$

Posledično za spremembo temperature velja relacija:

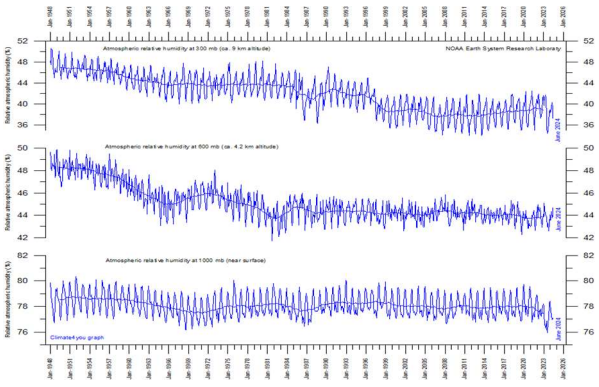
$$\Delta T_\mathrm{p} = \Delta F\{T_\mathrm{p}/[S_0(1-\alpha)]\} \tag{8}$$

kjer je temperatura površja $T_\mathrm{p} = 288$ K. Zato je sprememba temperature za podvojitev koncentracije CO_2 enaka le 1,1°C.

Ker se vrednosti za območje ECS ne ujemajo s ΔT_p, si pri IPCC pomagajo z domnevo o obstoju pozitivne povratne zanke prek

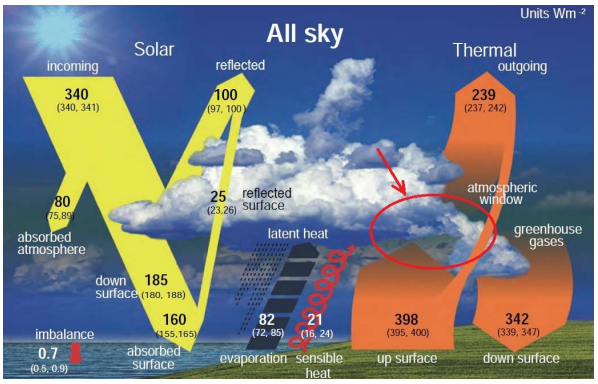
vodne pare, ki naj bi ojačala učinek CO_2 za približni faktor 3×. Razlaga gre nekako takole: ozračje, segreto zaradi povečanja vsebnosti CO_2, lahko sprejme več vlage (7% več za vsako 1°C po Clausius-Clapeyronovi relaciji), zato se zrak še bolj segreje, ter lahko sprejme še več vlage, in tako v krog, dokler se ne vzpostavi novo sevalno ravnovesje.

Vendar meritve zračne vlažnosti (relativne in absolutne) ne potrjujejo te domneve, kot je razvidno na **Sliki 3**, na kar je leta 2023 opozoril tudi Nobelovec John Clauser, pa je takoj doživel hude kritike z vseh strani, a povsem neupravičeno.



Slika 3: Satelitske meritve zračne vlažnosti na različnih višinah med januarjem 1948 in junijem 2024. Vir podatkov NOAA, povzeto po <http://climate4you.com>.

Na podlagi vseh predstavljenih formul so pri IPCC konstruirali sicer dokaj zapleten fizikalni model procesov v ozračju, kar pa zelo poenostavljeno prikazuje **Slika 4**:



Slika 4: Pretoki sevalne moči v zemeljskem ozračju. Številke predstavljajo gostote sevalnih moči posameznih procesov v enotah W/m^2. Vendar v območju označenem z rdečo elipso manjka pomemben podatek! Vir: IPCC AR6 [3].

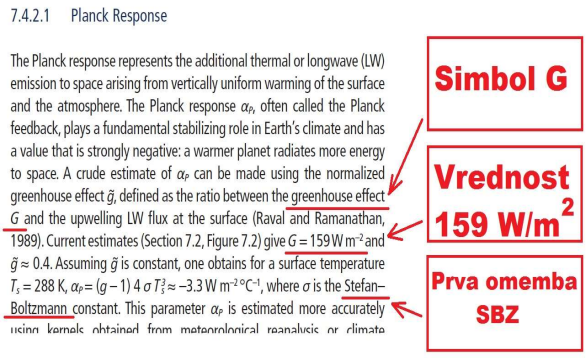
Parametre modela določa 12 števil (v oklepajih so navedene meje območja zanesljivosti), pri čemur vpadno kratkovalovno sončno sevanje na levi in izstopno dolgovalovno zemeljsko sevanje na desni približno ustrezata prej izračunanim številkam: četrtina sončnega sevanja (1361/4 = 340,25 W/m^2) zmanjšana za albedo, ter nekaj absorpcije v ozračju, segreva tla s kakšnih 160 W/m^2, zemeljsko površje izseva okoli 398 W/m^2 (mi smo izračunali 390), ozračje pa izseva kakšnih 239 W/m^2 v vesolje (sateliti sicer izmerijo le 232 W/m^2).

Dopustimo lahko, da senzorji satelitov ne zajemajo celotnega frekvenčnega območja, zato lahko nastopi znatna razlika med 232 W/m^2 na **Sliki 2** in 239 W/m^2 na **Sliki 4**. Precej nelogično pa se zdi, da se v sistemu pretaka veliko več energije kot v sistem vstopa in izstopa, saj zgleda kakor da bi hladno osrednje ozračje, ki je pri −18°C, z dobrimi 342 W/m^2 dodatno segrevalo tla, ki so na +15°C, pa čeprav efektivni pretok navzgor ustreza razliki med 398 in 342 W/m^2. Matematično se sicer številke ujemajo, toda fizikalno je nesmiselno, če sistem, ki naj bi bil v termodinamičnem ravnovesju z okolico, vsebuje precej več energije kot vanj priteka in odteka. To nakazuje, da z načinom izračuna, oziroma ocenami posameznih parametrov sistema, kot jih privzema IPCC, mora biti nekaj hudo narobe.

Vendar to ni edina težava. V **Sliki 4** na mestu označenem z rdečo elipso manjka trinajsti (nesrečni?) podatek. Označba *greenhouse gases*, oziroma toplogredni plini sicer naznanja, da se tam dogaja nekaj pomembnega in da ti plini sevajo nazaj proti tlom 342 W/m^2, ni pa podatka o razliki med sevanjem tal in sevanjem višjih plasteh ozračja proti vesolju, kar je dejansko **definicija toplogrednega učinka**!

Seveda to lahko izračuna vsakdo sam iz podatkov na **Sliki 4**: 398 − 239 = 159 W/m^2. Vendar te oznake v grafu ni, ker bi se kdo spraševal kako lahko 398 + 80 − 342 = 136 W/m^2 ustreza 159 W/m^2 ? Ker se namreč tistih 82 in 21 W/m^2 v resnici porabi za mehansko delo, transport toplega in vlažnega zraka navzgor.

Nekakšno razlago vendarle najdemo v besedilu poročila IPCC AR6 in sicer v poglavju 7.4.2.1 Planck Response, **Slika 5**:



Slika 5: Iz poročila IPCC AR6, leta 2021; vir [4].

Kot opozarja prof. *Howard Hayden* [4], je to prvič po več kot 30 letih delovanja IPCC, da so toplogrednemu učinku dali simbol G, mu določili vrednost, $G = 159$ W/m^2, ter prvič eksplicitno omenili Stefan-Boltzmannov zakon!

Pa poglejmo kako se izide izračun sevalnega ravnovesja. Ta določa, da mora biti izstopno sevanje zemlje, j_Z, enako vstopnemu sončnemu sevanju j_S:

$$j_Z = j_S \tag{9}$$

Hkrati pa mora biti izstopno sevanje j_Z enako razliki med sevanjem površine tal j_P, in toplogrednim učinkom G:

$$j_Z = j_P - G \tag{10}$$

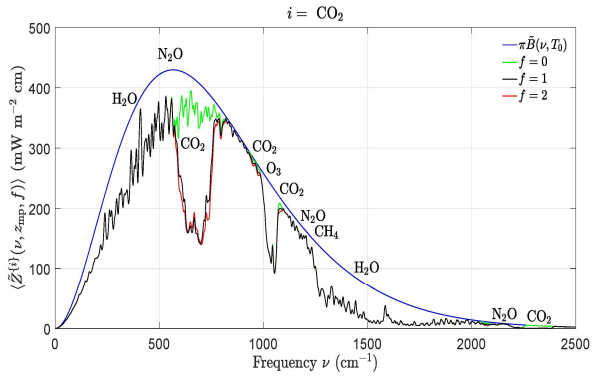
Iz (9) in (10) sledi, da mora biti tudi vstopno sončevo sevanje enako razliki med sevanjem tal in toplogrednim učinkom:

$$j_S = j_P - G \tag{11}$$

To pa si lahko predstavimo tudi grafično s Planckovimi spektri. Planckov spekter sevanja tal je mogoče teoretično izračunati s pomočjo Planckove relacije za odvisnost od valovne dolžine, kjer namesto frekvence uporabimo $\lambda = c/\nu$:

$$j_P(\lambda,T) = (2hc^2\lambda^{-5}) / (e^{hc/\lambda kT} - 1) \tag{12}$$

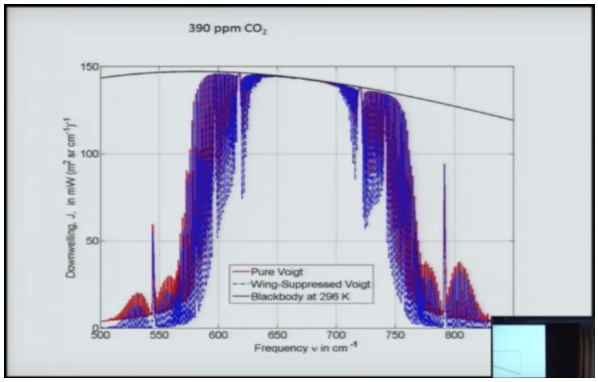
Povprečno globalno temperaturo tal smo že določili: $T = 288$ K. Za valovne dolžine pa vzamemo območje med 1 in 100 µm, kar je območje znotraj katerega je sevalni maksimum za to temperaturo (pri okoli 10 µm). Dovolj dobro ločljivost dobimo, če za korak pri valovnih dolžinah vzamemo $d\lambda = 0{,}1$ µm. Potem spektralna funkcija zgleda kot modra krivulja na **Sliki 6**:



Slika 6: Spekter sevanja tal (modra krivulja) za temperaturo $T = 288$ K po enačbi (12), v primerjavi s spektralno absorpcijo ozračja: črna krivulja je skupni spekter plinov ob sedanji vsebnosti CO_2, zelena krivulja je za primer brez CO_2, rdeča krivulja pa predstavlja učinek podvojitve vsebnosti CO_2. Na horizontalni osi je prostorska frekvenca v številu valov na cm.

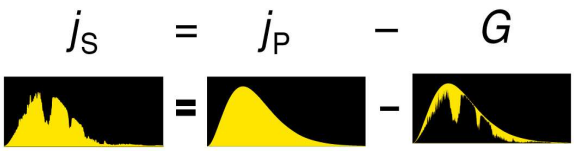
Spekter izstopnega sevanja planeta pa je mogoče bodisi izmeriti s sateliti, bodisi izračunati na podlagi empiričnih podatkov za posamezne pline v ozračju, ki so zbranih v podatkovni zbirki HITRAN, kot sta to naredila van Wijngaarden in Happer [5]. Črna krivulja na **Sliki 6** iz njihove študije velja za sedanjo vsebnost CO_2 v ozračju. Površina pod posamezno krivuljo je enaka izračunanim gostotam sevalne moči za sevalne gostote iz enačbe (11).

Iz **Slike 6** je razvidno, da podvojitev današnje koncentracije CO_2 ne bo privedla do večjih sprememb globalne povprečne temperature, saj je razlika med rdečo in črno krivuljo zelo majhna, znaša manj kot 2% celotnega absorbiranega sevanja v okolici dominantne resonance CO_2, ki je pri 15 µm, oziroma v okolici 666 valov na cm na horizontalni lestvici. To je posledica dejstva, da je spekter CO_2 že pri sedanji koncentraciji nasičen, ker preprosto ni več fotonov, ki bi jih lahko pri povečani koncentraciji zajel. To je razvidno na bolj podrobnem prikazu spektra na **Sliki 7**, kjer je vrh ostro omejen z gostoto sevanja tal, oscilacije pa so prisotne le na robovih spektra. Pri podvojeni koncentraciji bi se povečala le strmina robov, ker je pač absorpcijska energija kvantizirana z jakostjo medatomskih vezi CO_2, in spekter nima možnosti, da bi se še bolj razširil.



Slika 7: Podrobnejši prikaz spektra CO_2 v območju okoli dominantne resonance pri 15 µm, oziroma 666 valov na cm.

Vendar pa imamo še en pomembnejši dokaz, da so pri IPCC napačno ocenili učinek toplogrednih plinov. S pomočjo Slike 6 in enačbe (11) lahko to nazorno pokažemo.



Slika 8: Prikaz enačbe (11) v grafični obliki.

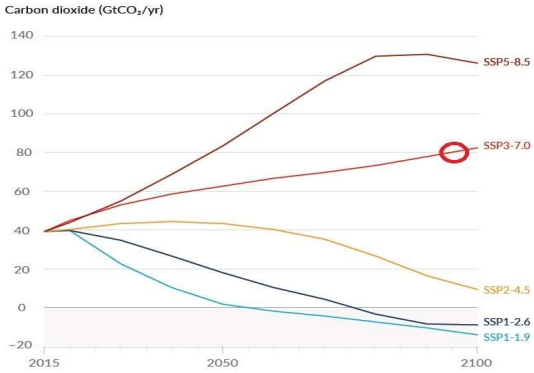
Ker se vstopno sončevo sevanje j_S skoraj konstantno, se tudi izstopno sevanje j_Z dolgoročno ne spreminja s koncentracijo CO_2 (kot potrjuje tudi **Slika 2**). To pomeni, da mora biti sprememba G natančno enaka spremembi sevanja površine, j_P. Za podvojitev koncentracije CO_2 smo že z enačbo (7) izračunali spremembo gostote sevalne moči, ta prispeva 3,7 W/m^2. Za toliko bi se v teh okoliščinah povečal tudi toplogredni učinek G.

Vendar pri IPCC podajajo drugačno oceno, pravzaprav več različnih ocen odvisno od posameznega scenarija znižanja izpustov toplogrednih plinov. Ti scenariji se v AR6 imenujejo *Shared Socio-economic Pathways*, SSP. Vsakemu SSP scenariju so dodelili drugačno stopnjo znižanja izpustov, učinek pa so potem označili z dvema številoma, prvo število pomeni predvideni porast temperature, drugo število pa je pripadajoče povečanje gostote sevalne moči.

Za zgled vzemimo SSP3-7.0, (**Slika 9** in **Slika 10**) ki v AR6 predstavlja primer, ko bi se izpusti še naprej povečevali po sedanji stopnji in za njihovo zmanjševanje ne bi naredili ničesar (temu scenariju pravijo *Business As Usual*). Predvidevajo da bi se v tem primeru količina izpustov CO_2 podvojila leta 2095.

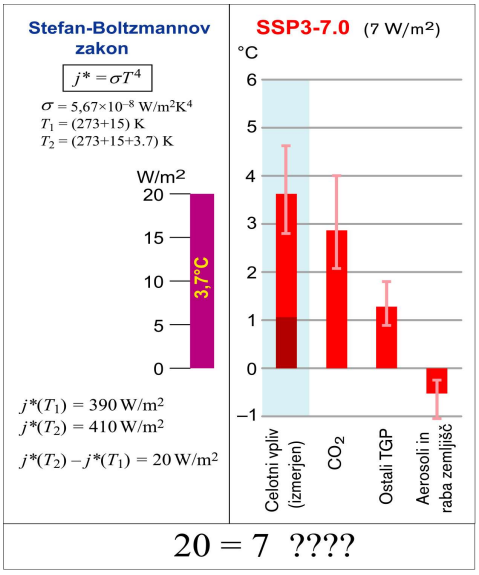
Torej bi se od leta 2015 do leta 2095 izpusti povečali s sedanjih 40 na 80 milijard ton na leto. Ta prirast pomeni vsako leto

dodatnih 0,5 milijarde ton CO_2. Toda meritve vsebnosti CO_2 zadnjih 60 let kažejo, da ta narašča za polovico počasneje kot naraščajo izpusti, saj polovico sproti posrkajo naravni ponori (oceani in fitoplankton, kopenske rastline in bakterije v tleh). Sedanja celotna količina CO_2 v ozračju znaša 3200 milijard ton. Če torej vsako leto v ozračju ostaja dodatnih 0,25 milijarde ton, bi ob sedanji stopnji rasti izpustov skupno količino CO_2 podvojili v 65 letih od leta 2015, oziroma že leta 2080.



Slika 9: Predvideni scenariji zmanjševanja izpustov po IPCC. Scenarij SSP3-7.0 predvideva nadaljnje povečevanje izpustov po sedanji letni stopnji, kar naj bi leta 2095 privedlo do podvojitve letne količine izpustov (rdeči krogec).

Kako verjetni so ostali scenariji najbrž nima smisla razpravljati. Poglejmo bilanco sevalne moči za SSP3-7.0 po oceni IPCC. Predvideva se najverjetnejši porast temperature za 2,6°C (oziroma najverjetneje v območju med 2 in 5°C) nad sedanjo temperaturo, ki je že za 1,1°C višja od temperature leta 1850, skupno torej 3,7°C; to pa naj bi ustrezalo povečani gostoti sevalne moči za 7 W/m^2, **Slika 10**:



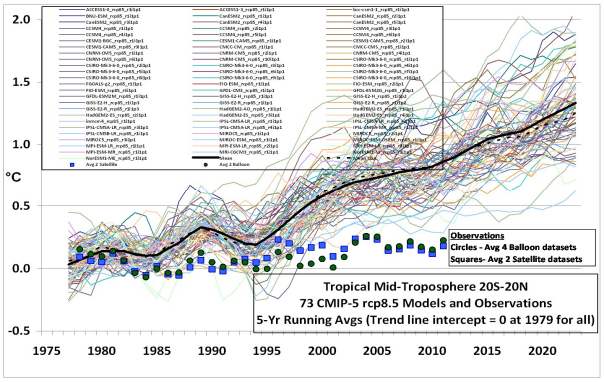
Slika 10: Na desni polovici slike je scenarij SSP3-7.0, povzet po AR6, str. 13 [6]. Na levi pa je izračun gostote sevalne moči za predvideno temperaturno razliko po Stefan-Boltzmannovem zakonu. Številke se ne ujemajo.

Kot vidimo na desni strani **Slike 10**, znaša izmerjeno povečanje povprečne globalne temperature od leta 1850 do danes okoli 1,1°C, nad tem pa je dodano najverjetneje povečanje v primeru podvojitve celotne količine CO_2 v ozračju, kar je ocenjeno na 2,6°C, skupno torej 3,7°C. Od tega odpade samo na CO_2 okoli 2,9°C, ostali toplogredni plini prispevajo še 1,3°C, izpusti aerosolov pa ohladijo ozračje za okoli 0,5°C. Po scenariju SSP3-7.0 se to povišanje temperature zgodi zaradi povečanega toplogrednega učinka za 7 W/m^2.

Toda po Stefan-Boltzmannovem zakonu povišanju temperature za 3,7°C ustreza povečanje gostote sevalne moči za 20 W/m^2.

Kako je lahko 20 = 7? Na to vprašanje ni odgovora. Sklepamo lahko le, da pri IPCC že v osnovi niso pravilno zastavili problema in je model na **Sliki 4** vsaj pomanjkljiv, če že ne povsem napačen, pa tudi to, da se nihče ni potrudil preveriti kako se sedanje sevalno ravnovesje planeta ujema s tistim predvidenim za primer podvojitve vsebnosti CO_2 v ozračju.

Dodatna težava je, da je ta napaka v klimatski občutljivosti za faktor 3× vgrajena v vse računalniške klimatske modele in so posledično vse napovedi rasti temperature do konca tega stoletja močno pretirane. To dejstvo je bilo očitno že leta 2010, ko sta dr. *Roy Spencer* in dr. *John Christy* zbrala in objavila napovedi rasti temperature 73 računalniških klimatskih modelov, ter jih primerjala s temperaturami izmerjenimi do leta 2010 s sateliti in meteorološkimi baloni, **Slika 11**:



Slika 11: Napovedi rasti globalne temperature 73 računalniških klimatskih modelov od leta 1978 do leta 2023 v primerjavi z izmerjenimi temperaturami do leta 2010 (tenke črte so napovedi potekov temperatur posameznih modelov, debelejša črna črta je njihovo 5-letno povprečje, modri kvadratki predstavljajo letna povprečja satelitskih meritev, črni krogci pa so meritve z meteorološkimi baloni).

Žal ta napaka ni brez posledic tudi v realnem svetu, gre namreč za verjetno najdražjo računsko napako v zgodovini človeštva. Zaradi te napake je bilo do sedaj na svetovni ravni po nepotrebnem zapravljeno po grobi oceni več kot 18 bilijonov ameriških dolarjev (samo v Nemčiji je bilo za njihov program *Energiewende* v 15 letih porabljenih okoli 600 milijard evrov, v ZDA pa 3800 milijard dolarjev). Posredna škoda pa je še mnogo večja, saj je zaradi tega bilo po svetu ustavljenih veliko investicij v energetski, industrijski in kmetijski razvoj, kar bi prineslo velik

družbeni napredek, še zlasti v državah v razvoju bi to v veliki meri pripomoglo k zmanjšanju revščine in lakote.

3 Zaključek

Izračuni s katerimi IPCC, za njimi pa pretežni del svetovne politike in množičnih medijev ustrahujejo prebivalstvo s posledicami prihodnjih podnebnih sprememb in posledično upravičujejo uvajanja raznih omejitvenih ukrepov s ciljem zmanjševanja izpustov toplogrednih plinov, vsebujejo številne napake. Nekaj najbolj resnih je opisanih v tem članku, izračuni dokazujejo, da je ocenjen vpliv toplogrednih plinov na podnebje prevelik vsaj za faktor 3×. Zaskrbljujoče je, da se o teh napakah ne govori niti v znanstvenih krogih, pa je ravno znanost tista, ki bi morala vse tovrstne teoretične predpostavke in na njih zasnovane izračune sproti temeljito preverjati in morebitne napake odpravljati. Da se to ne dogaja je najbrž posledica dejstva, da so tudi mnogi znanstveniki podlegli političnim pritiskom in grožnjam z omejevanjem financiranja znanstvenih raziskav tako samim znanstvenikom kot njihovim institucijam, če bi javno dajali izjave, ki ne soglašajo z uradnimi političnimi opredelitvami do problemov vpliva na podnebje. To seveda ne pomeni, da vpliva človeških dejavnosti na podnebje ni. Vendar bi morali biti ti vplivi realno ocenjeni, morebitni nujni omejevalni ukrepi pa temeljito pretehtani in sorazmerni, predvsem pa naj ne bi povzročali več škode kot koristi.

Vrednost električne energije intermitirajočih virov in kanibalizem na trgu z električno energijo

Value of Electricity From Intermitend Sources and Electricity Market Cannibalism

Rafael Mihalič
UL, Fakulteta za elektrotehniko
Tržaška 25
Ljubljana, Slovenija
rafael.mihalic@fe.uni-lj.si

POVZETEK

Intermitirajoči viri električne energije (OVE), predvsem vetrne (VE) in sončne elektrarne (SE), prevzemajo vedno večji delež v proizvodnji električne energije. V Sloveniji je rast količine SE eksplozivna. Ta razvoj lahko pripišemo subvencijam in privilegiranemu položaju na trgu. Če naj bi bila "veter in sonce zastonj" in subvencije kljub temu potrebne, se lahko upravičeno vprašamo: "Koliko pa je na trgu sploh vredna električna energija iz OVE?"

V članku smo zato za Nemčijo in Slovenijo analizirali tržno vrednost proizvodnje OVE za leto 2023 in prvo polovico leta 2024. Izračuni so temeljili na javno dostopnih podatkih.

Izkazalo se je, da zaradi lastnosti OVE in obratovalnih značilnosti elektroenergetskega sistema (EES) tako v Nemčiji, kakor Sloveniji, pride do izrazitega tako imenovanega kanibalskega učinka na trgu. V Sloveniji omenjeni učinek zmanjša tržno vrednost energije iz SE v letu 2024 na nekaj nad polovico tiste, ki bi jo pričakovali, če v EES ne bi bilo SE. Ta vrednost je le malo nad tisto v Nemčiji, čeprav je relativni delež energije iz SE približno 2 x manjši, kot v Nemčiji. Sklepamo, lahko, da zaradi povezanosti Entso-e sistema Nemci problem kanibalizma cen deloma "izvažajo", mi pa "uvažamo".

Pri vsem tem nismo upoštevamo stroškov obratovanja in nadgradnje EES zaradi OVE. Že samo "redispatching" potisne vrednost energije iz Nemških SE navzdol proti ¼ pričakovane vrednosti (tiste brez SE v EES).

Brez slabe vesti lahko torej trdimo, da se bo dejanska tržna vrednost energije bodočih OVE ob trenutnem trendu rasti hitro bližala vrednosti 0. In to ne upoštevajoč dodatnih stroškov EES zaradi OVE.

ABSTRACT

Intermittrnt electricity sources (RES), in particular wind power (WT) and solar energy (SE), are accounting for an increasingly large share of electricity generation. In Slovenia, the growth of SE is explosive. This development is due to subsidies and a privileged position on the market. If 'wind and sun are free' and subsidies are nevertheless necessary, one can rightly ask: 'How much is electricity from renewable energies worth on the market?'.

In this article, we have therefore analysed the market value of renewable energy generation for Germany and Slovenia for 2023 and the first half of 2024. The calculations are based on publicly available data.

It turns out that due to the characteristics of RES and the operating characteristics of the electric power system (EPS), there is a pronounced so-called cannibal effect on the market in both Germany and Slovenia. In Slovenia, this effect reduces the market value of energy from SE in 2024 to just over half of what would be expected if there were no renewables in the EPS. This value is only slightly higher than in Germany, although the relative share of energy from SE is only about half as high as in Germany. From this we can conclude that, due to the interconnectedness of the Entso-e system, the Germans are partly 'exporting' the problem of price cannibalism, while we are 'importing' it.

None of this takes into account the costs of operating and upgrading the EPS for renewable energies. Redispatching alone reduces the value of energy from German SE to ¼ of the expected value (that without renewables in the EPS).

It is therefore safe to say that the real market value of energy from future RES will quickly approach 0 given the current growth trend.

KLJUČNE BESEDE

Obnovljivi viri energije, OVE, cene električne energije, elektroenergetski trg, tržna vrednost električne energije, kanibalski učinek

KEYWORDS

Renewables, RES, Electricity prices, Electricity market. Market value of electric power, Cannibalisation effect

1 UVOD

V predhodnem prispevku (na istem mestu pred enim letom) [1] smo analizirali problem ovrednotenja investicij v obnovljive vire energije (OVE). Kakor je bilo izpostavljeno, splošno sprejeta metodologija izrazito favorizira izgradnjo OVE in ne upošteva vrste dejavnikov in potrebnih investicij v prilagoditev celotnega elektroenergetskega sistema (EES).

Hkrati odpira vrsto ne le ekonomskih, pač pa splošnih družbenih dilem povezanih s pojmovanjem enakopravnosti ljudi v družbi v smislu "*quod licet iovi non licet bovi*" (pomensko: "Kar je dovoljeno nekaterim, ni dovoljeno drugim!"). Dodatno gre pri tem za politično pogojeno prerazporeditev premoženja ljudi, če uporabimo blagi izraz.

Izkazalo se je tudi, da v primeru "nekega zmernega" deleža OVE v določenem EES kakih večjih problemov in v prispevku izpostavljenih dilem ni oz. so zanemarljive in problemi tehnično obvladljivi z obstoječim EES. Kakor pa delež OVE zraste nad omenjeni "zmerni delež" in se začne bližati politično sprejetim in ekonomsko in tehnično nerazumnim mejam, pa problemi (in stroški) eskalirajo. Kje je meja tega "zmernega deleža" je vprašanje za milijon dolarjev in je skoraj ni moč izračunati. Pogojena je s strukturo EES, lastnostmi in vrsto virov električne energije, lastnostmi porabnikov itd. Pa tudi, če bi bila znana, to za politiko, za religiozno prepričane ljudi in oportuniste ne bi pomenilo veliko. Pač v smislu "*après nous, le déluge*" (za nami potop).

Za neko družbo oz. državo, kot celoto, torej velja, da omenjenega "zmernega deleža" ni smiselno preseči. Še zdaleč pa ne velja za akterje na trgu, ki v taki situaciji lahko pridobijo velike ekonomske koristi. V tržnem gospodarstvu s tem sicer ni nič narobe, problem pa je, da so te koristi pogojene s siromašenjem tihe večine in z "zdravo konkurenco" nimajo veliko opraviti. Zlobneži bi to pospremili s pripombo o "ribarjenju v kalnem" in na situacijo lahko v določeni meri gledamo tudi s tega stališča, saj večini ljudi niti približno ni jasno, kako zadeve potekajo in za kaj gre. Edino, kar opazijo je, da se vse draži, plače capljajo bolj ali manj na mestu ali zelo obotavljivo in z velikim časovni zamikom skušajo slediti inflaciji, na sosednjih vilah so "en, dva, tri" zrasle sončne elektrarne preko celih streh in prizidkov, njim pa "elektro" ne dovoli postaviti par panelov na uti, ker so "kapacitete omrežja izčrpane".

V tržnem gospodarstvu pač razvoj družbe diktirajo pravila trga, zato si v nadaljevanju poglejmo, kakšno vlogo na njem igrajo intermitirajoči OVE (sončne, vetrne elektrarne) in kakšna je dejanska tržna vrednost njihove električne energije. Z drugimi besedami; zanima nas, koliko bi bila na trgu vredna električna energija OVE, če bi za vse nove OVE elektrarne ta trenutek ukinili njihov privilegirani položaj na trgu z električno energijo in bi bile te povsem izenačene s "klasičnimi" viri.

Pri analizi smo pod drobnogled vzeli zadnjo leto in pol dogajanja na nemški in slovenski borzi z električno energijo. Omenjeno časovno obdobje smo izbrali, ker podatki zaradi pretresa in spremembe funkcioniranja celotne družbe med "obdobjem covida" niso relevantni, po drugi strani pa je večanje instalirane moči in s tem deleža OVE pri proizvodnji električne energije tako hiter, da analiza stanja pred letom 2020 ne bi imela nobenega smisla.

Nemčija je bila izbrana, ker gre za državo, ki je po eni strani sinonim za "*Energiewende*" (energijski preobrat) in zaradi njene ekonomske in politične teže v veliki meri diktira evropsko politiko na tem področju, po drugi strani pa ima odličen sistem javno dostopnih podatkov povezanih s proizvodnjo virov električne energije (recimo [2, 3]). Pri Sloveniji smo se seveda omejili le na sončne elektrarne (SE), saj je prispevek vetrnih elektrarn (VE) zanemarljiv.

2 OSNOVE TRGA ELEKTRIČNE ENERGIJE "ZA TELEBANE"

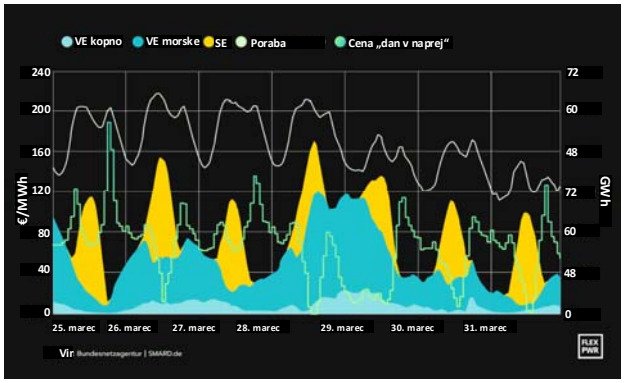
Principi trgovanja z električno energijo v Evropi so relativno zapleteni in so za povprečnega prebivalca Evrope prej, kot ne, španska vas. Tudi elektrotehniki na področju elektroenergetike, ki se z omenjenim trgom (v nadaljevanju označujemo s "trg" dejavnosti povezane s trgovanjem z električno energijo) ne ukvarjamo neposredno, se večinoma ne moremo pohvaliti z ekspertnim znanjem na tem področju. Ker pa razvoj EES v veliki meri diktira prav trg, je potrebno poznati vsaj njegove osnove, saj sicer ni mogoče niti razumeti, niti predvideti, niti načrtovati prihodnjega razvoja EES. Zlasti slednje dejstvo pa je ključnega pomena za zanesljivo dobavo električne energije in ga opisuje znana krilatica: "Ko se v EES pojavijo problemi, je že 10 let prepozno." Torej si v nadaljevanju oglejmo nekaj osnovnih dejstev v smislu serije knjig "Za telebane", ki se jih nekoliko izkušenejši še dobro spomnimo in so predstavljale pravo odrešitev za povprečne uporabnike česarkoli že.

Trg z električno energijo v EU so začeli uvajati ob koncu prejšnjega stoletja in se od tedaj neprestano razvija. Že v 80-tih je Evropska komisija začela zagovarjati tako imenovani prosti evropski trg z električno energijo. Prej so bili namreč EES bolj ali manj omejeni na posamezne države. Povezovanje EES med seboj in vzpostavljanje velikega sinhrono delujočega sistema je tehnično in regulatorno izjemno kompleksna naloga in lahko traja reda desetletja, kakor kaže praksa pri priključitvi dežel vzhodnega bloka po padcu železne zavese. Ima pa velik, povezan EES, velike prednosti pred majhnim in omogoča zanesljivejše in cenejše obratovanje. Ker gre za tehnično zelo zapleten sistem, pri katerem je, zato da sploh lahko stabilno obratuje, potrebno zagotavljati določene tehnične pogoje in upoštevati tehnične omejitve, mora biti tudi trg z električno energijo z jasnimi pravili in omejitvami zasnovan tako, da je skladen s tehničnimi pogoji za varno obratovanje EES. Elektrika je namreč izrazito neprimerno blago za trgovanje in lahko bi rekli, da zanjo prosti trg ni ustrezna rešitev. Problem pa je, da zaenkrat v družbenem sistemu, v katerem živimo, boljše rešitve ne poznamo.

Osnova obratovanja EES je dejstvo, da se ta mora sproti prilagajati (zagotavljati energijo) porabi, ki se tekom vsake minute, ure, dneva, tedna, sezone ves čas spreminja. Skratka proizvodnja in poraba morata biti ves čas v ravnotežju. To ravnotežje pa zagotavljajo elektrarne z neprestanim prilagajanjem proizvodnje. Različne elektrarne pa imajo različne obratovalne karakteristike, različno sposobnost prilagajanja proizvodnje, različne načine in čase zagona, različne investicijske stroške, različne tekoče stroške (cena primarnega energenta, na primer goriva), različne stroške zagona, različne dinamične lastnosti, različne možnosti zaustavitve (pri npr. jedrskih elektrarnah sta zaustavitev in ponoven zagon kompleksen in dolgotrajen, več dni trajajoč proces, povezan z velikimi stroški), pa še kaj bi se našlo. Stohastični OVE (VE, SE) dandanes nimajo sposobnosti prilagajanja potrebam EES, kar sicer ne pomeni, da je tehnično ne bi mogle imeti, vendar za ceno manjših dobičkov, v kolikor to ne bi bilo podprto s še dodatnimi subvencijami. Ker torej OVE nimajo ene od osnovnih lastnosti, ki jih elektrarne *morajo* imeti, jih pravzaprav ne moremo imenovati "elektrarne". To so stohastični viri električne energije in kar "narava da", pač proizvedejo. Tu pa se že nakazuje, kam pes taco moli. Razliko med proizvodnjo in porabo (ki se ves čas

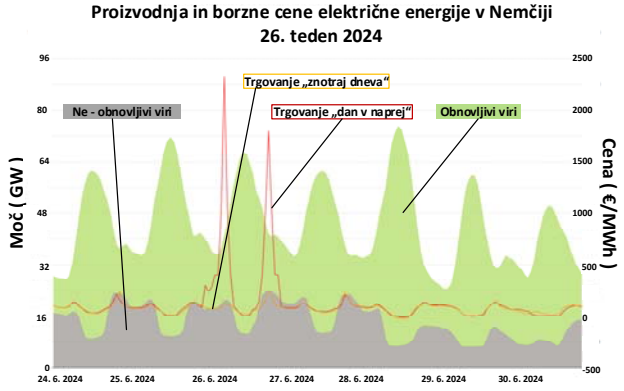
spreminja) morajo izravnavati "klasični" viri (ali v prihodnosti shranjevalniki električne energije, ki pa so zaenkrat za resno sistemsko shranjevanje za red velikosti predragi, razen tega pri današnji tehnologiji na Zemlji še zdaleč niti ni dovolj surovin zanje). Seveda obstaja tudi možnost prilagajanja porabnikov (prostovoljnega ali prisilnega – beri izklopi), ampak s tem je razkošja kadarkoli dostopne elektrike za ljudi konec in znamenite redukcije iz 80-tih let v katerih ne bi uživali verjetno niti največji nostalgiki, lahko doživijo renesanso.

Omenjeni problemi so tem večji, čim večji je delež OVE. Kljub posebnostim trga z električno energijo, pa na njem vendarle še vedno veljajo klasična tržna pravila, torej če je blaga veliko, je poceni, če ga je malo, pa je drago. Ker je električna energija za funkcioniranje družbe nujna, zato lahko ob pomanjkanju doseže neverjetne cenovne skoke (v J. Avstraliji npr. v nekaj urah skoraj 300+ - kratnik, torej 30 000 % dolgoletnega povprečja [4]). Še zanimivejša je situacija, ko je elektrike preveč. Nekaterih elektrarn in tisočev SE namreč ni moč poljubno izklapljati. Takrat doseže električna energija na borzi vrednosti blizu nič ali celo negativne vrednosti (V smislu: "Plačamo, samo vzemi!"). Ilustracijo prikazuje slika 1.



Slika 1: Proizvodnja OVE in cena na borzi EPEX (Nemčija) zadnji teden marca [5]

Jasno je razvidno, da sta cena na borzi in proizvodnja OVE obratno korelirani. Še bolj zanimiva je situacija na isti borzi junija in julija, kjer je cena v 12 urah skočila iz vrednosti malo nad 0 na skoraj 2500 €/MWh in nazaj na 0 ter v naslednjih 12 urah podobno – slika 2, 14. junija pa je bila cena okrog poldneva negativna, približno –150 €/MWh (negativen trikratnik neke povprečne borzne cene).



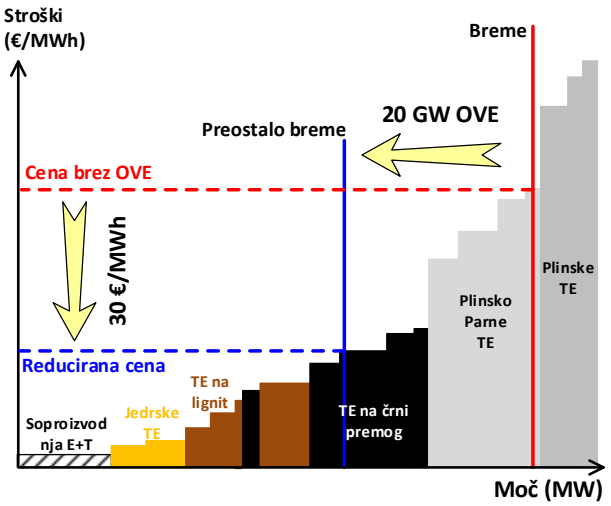
Slika 2: Proizvodnja OVE in cena na borzi EPEX (Nemčija) zadnji teden junija [1]

Mesec dni kasneje, 14. julija, je bila cena negativna med 8. uro zjutraj in 17. uro.

Ob tem se lahko upravičeno vprašamo, kak smisel sploh ima graditi recimo dodatne SE, če je pa takrat, ko proizvajajo največ, cena elektrike skoraj nič, in kako se obstoječim izide račun. Kratek odgovor je: "Ker so subvencionirane in njihov dohodek ni odvisen le od tržne cene." Torej lastnikov kaj dosti ne motijo negativne cene na borzi. Seveda pa to vpliva na vse udeležence na borzi. Problematične so zlasti elektrarne, ki rabijo dolgo časa (beri: je drago) za zagon in tiste, ki imajo sicer nizke stroške obratovanja in velike stalne stroške (beri: velika investicija) in torej za rentabilnost potrebujejo veliko obratovalnih ur. Tipično gre za jedrske elektrarne, dobre premogovne elektrarne z visokim izkoristkom, plinsko-parne elektrarne, lahko tudi za pretočne hidroelektrarne oz. elektrarne z majhno akumulacijo (ravno včeraj, 5. 7. sem iz prve roke izvedel, da hidroelektrarne na Savi že ves mesec po malem prelivajo vodo, ker je elektrike čez dan preveč in je sistem ne more absorbirati).

V takih razmerah se elektrarn z nizko ceno primarnega energenta in visokimi investicijskimi stroški (beri: dobrih, energetsko učinkovitih elektrarn) ne izplača graditi. Ob nespremenjenem trendu bi količina OVE narasla do meje, ko bi ob ugodnih naravnih danostih proizvajali velike presežke električne energije, ki bi jih bodisi na nek način "metali vstran" (recimo s prelivanjem vode v hidroelektrarnah in/ali zaustavitvijo jedrskih elektrarn) ali shranjevali v hranilnikih električne energije. Problem je, da so za shranjevanje na sistemskem nivoju ti pri obstoječi tehnologiji za red velikosti predragi, razen tega zanje na Zemlji ni dovolj surovin. Na OVE in hranilnikih temelječ EES je sicer tehnično teoretično mogoče izgraditi, vendar njegove cene niti najbogatejša družba ne bi mogla plačati.

Ob tem še enkrat poudarimo, da pri dosedanji razpravi o ceni elektrike gre za ceno, ki bi jo dosegla na borzi dodatna elektrarna (marginalna cena), in da ne moremo celotne količine električne energije iz OVE ovrednotiti po tej ceni (marginalni). To bi veljalo le za ta trenutek dodano dodatno elektrarno. Če bi namreč odvzeli vso električno energijo OVE, bi se cene drastično spremenile. Logiko ponazarja slika 3.



Slika 3: Logika določanja cene na borzi Vir: prirejeno po[6]

Na sliki 3 je obrazložena logika določanja borzne cene po obstoječih pravilih. Na abscisni osi je potrebna moč porabe in/ali proizvodnje, predvidena za npr. določeno uro prihodnjega dneva, na abscisi pa je cena za 1 MWh električne energije. Višina bar diagramov predstavlja minimalno ceno, ki jo lahko na trgu ponudijo posamezne elektrarne (na MWh). V bistvu gre za lastno ceno proizvodnje, pod katero bi proizvajale izgubo. Cena zadnje elektrarne, ki je potrebna za zadovoljitev porabe (recimo stičišče polne in črtkane rdeče črte) potem velja (toliko dobijo plačano) za vse elektrarne na levi strani. Problem te logike je, da se OVE privzeto postavijo s ceno 0 na začetek tega diagrama. Na ta način imajo zagotovljen odjem, kar je po "zdravi kmečki logiki" povsem ustrezno. Na ta način se poraba iz "klasičnih" elektrarn zmanjša (na sliki 3 konkretno za 20 GW), saj jo pokrijejo OVE. Posledično se "rdeča črta" pomakne v diagramu proti izhodišču na območje cenejših elektrarn (modra črta).

To ima dve, pravzaprav tri posledice. Prva posledica je, da dobre plinsko – parne elektrarne in elektrarne na črni premog ostanejo "brez posla" – glej sliko. Če se to dogaja pogosto, postanejo nerentabilne in bankrotirajo. Druga posledica je, da vse elektrarne levo od modre črte zaslužijo manj. Za fiksno subvencionirane OVE (tudi t. i. "net-metering" lahko štejemo v to skupino) to ni tak problem, za ostale pa je. Tretja posledica pa je pravzaprav posledica prvih dveh in pomeni, da nihče ne bo več investiral denarja v dobre elektrarne z dobrim izkoristkom, ki pa jih je praviloma problematično pogosto zaganjati/ugašati oz. jim močno variirati obremenitev. Po tej logiki se bo izplačalo graditi le poceni elektrarne s slabim izkoristkom in zelo dragim primarnim energentom. Slednje ni ovira, saj ko OVE "presahnejo", je cena samo nebo ("sky is the limit") – glej npr. sliko 2.

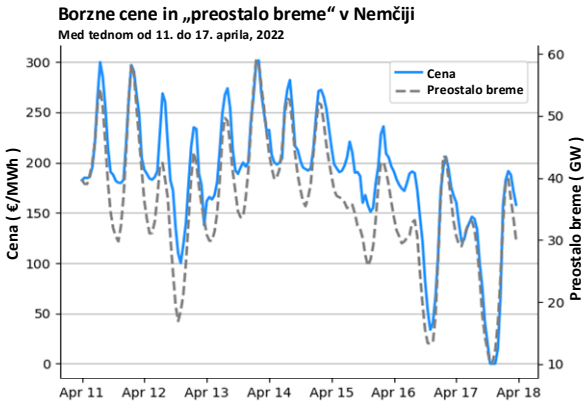
Še opomba; na sliki 3 nas ne sme zavesti nizka cena jedrskih elektrarn. Gre za spremenljive stroške, ki so pri njej zelo nizki. Če bi upoštevali investicijo, pri tej ceni ne bi bila nikoli rentabilna. To dejstvo je seveda odločilno za investicije v nove objekte.

Na ta način pa se tudi dejanska tržna vrednost proizvodnje OVE zmanjša. Več je OVE, bolj je ta pojav izrazit, bolj se niža tržna cena drugim elektrarnam in tudi samim OVE. Govorimo o tako imenovanem učinku kanibalizma ("cannibalisation effect").

Omenjena razlaga opisuje osnovni princip, obstaja še kup dodatnih mehanizmov, ki tehnično omogočajo, da EES stabilno obratuje in lahko ceno potisnejo tudi v negativne vrednosti (kar po opisani logiki ni mogoče).

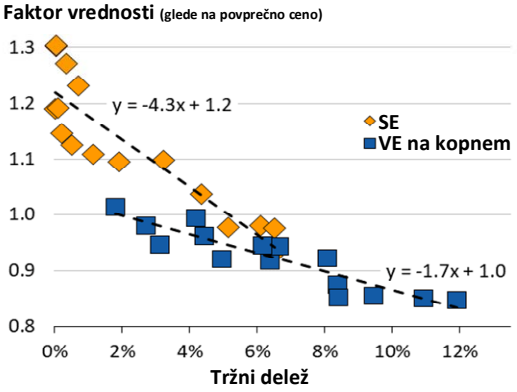
Podrobnejši ekonomski izračuni so razmeroma kompleksni in podrobneje razložijo, zakaj z večanjem subvencioniranih SE in VE privede do padca vrednosti njihove električne energije na borzi proti ali celo pod 0.

Pri zelo majhnem deležu OVE v EES cena oz. vrednost električne energije sledi logiki, ki smo jo poznali pred desetletji. Ponoči in med dela prostimi dnevi, ko večina ljudi in industrije rabi manj elektrike, je cena nizka, podnevi pa je poraba bistveno višja in temu ustrezno tudi cena. Zato je vloga SE v začetku za obratovanje EES pozitivna. Slika pa se diametralno spremeni, če recimo SE v nekem EES proizvedejo reda 10 ali 15 % elektrike. Majhni omenjeni številki sta lahko zavajajoči in delež SE lahko pomeni za EES veliko večji problem, kot bi lahko sklepali iz njiju. Namreč, SE imajo v Sloveniji obratovalne ure, ali bolj po domače, izkoriščenost (koliko dejansko proizvedejo v primerjavi z njihovim teoretičnim maksimumom = maksimalna osončenost 24 ur na dan), nekje okrog 10%. To pomeni, da je pri 10% deležu proizvodnje vgrajena moč SE okrog povprečne proizvodnje sistema. Ko torej sonce zasije opoldne povsod "na polno"(se zgodi tu in tam), SE praktično pokrijejo porabo. Kam pa z viški iz elektrarn, ki jih ni moč zaustaviti? Možnosti je sicer več, a nobena ni ravno poceni. Nemci npr. v takih primerih izvažajo elektriko skoraj zastonj, zvečer (ko SE "ugasnejo") pa jo po zelo visoki ceni uvažajo. In potem se ljudje čudijo, da se elektrika draži, in da ima Nemčija skoraj najdražjo elektriko na svetu?! Ilustracija je na sliki 4, ki prikazuje ceno elektrike (modra krivulja) v odvisnosti od t. i. preostalega bremena (residual load), se pravi bremena, ki ga ni moč pokriti z OVE (modra vertikalna črta na sliki 3), pač pa s klasičnimi elektrarnami (ali uvozom). Če OVE pokrijejo skoraj vso porabo, je seveda preostalo breme majhno (slika 3 – modra črta gre levo, črtkana modra črta pa se pomika navzdol) in cena pade, v skrajnem primeru na 0.



Slika 4: Kanibalska logika; več OVE, manjša cena [7]

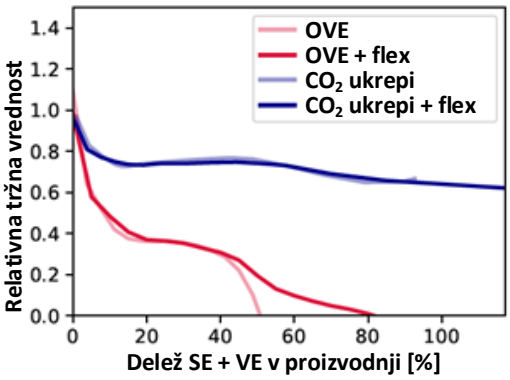
Konkretne izračune so za Nemčijo na podlagi borznih podatkov izvedli v [5] – glej sliko 5 (vsak kvadratek predstavlja eno leto)! Čeprav so podatki stari in delež OVE še relativno majhen, je logika nedvoumna. Hkrati potrjuje tudi omenjeno premiso, da majhen delež SE na obratovanje EES vpliva blagodejno, saj SE proizvajajo podnevi, ko je poraba (in cena) električne energija višja. Zato je tudi "faktor vrednosti" na začetku okrog 1,3 (130 % povprečne cene) in je nekako do 5 % deleža proizvodnje iz SE nad 1.



Slika 5: Kanibalska logika – dolgoročni trend [6]

Opisana logika je v ekonomiji že dolgo znana in nekaj avtorjev se je problema lotila znanstveno, pri čemer so upoštevali zakonitosti trga v EU, karakteristike EES, možnosti prenašanja

energije po EE omrežju itd. Gre za relativno obsežne izračune, za ilustracijo pa podajamo sliko 6. Avtor prispevka [7] je analiziral scenarije razvoja vrednosti električne energije OVE v odvisnosti od večanja njihovega deleža v proizvodnji EES. Pri tem je ugotovil, da samo s subvencijami, brez posebnih dodatnih ukrepov, vrednost njihove proizvodnje pri 50 % deležu pade proti 0. S povečanjem fleksibilnosti EES v smislu možnosti shranjevanja električne energije in prilagajanja porabnikov (oznaka "flex") je sicer mogoče nekaj narediti, vendar se pri višjem deležu OVE cena še vedno giblje blizu ničle. "Rešitev" je našel v spremembi regulative in drastičnem povečanju cene izpustov CO2. Kaj si o vsem skupaj mislim, kot davkoplačevalec, ni za objavo.



Slika 6: Ničvrednost energije iz OVE in "Dekanibalizacija" po ekonomistično [7]

3 IN MEDIAS RES ALI KAJ PRAVIJO ŠTEVILKE

Kot je bilo že omenjeno, je vsak EES specifičen glede strukture, lastnosti in razporeditve virov, možnosti prenašanja energije, lastnosti porabnikov itd. Zato kvantitativna analiza scenarijev nekega EES, povezanih bodisi s tehničnimi lastnostmi ali ekonomskimi kazalci, v splošnem ne velja za nek drug EES ali, zlasti pri velikih EES (kar evropski EES je), ne velja niti za druga območja istega EES. Zato smo si zastavili vprašanje: "Kje na teh grafih iz prejšnjega poglavja pa se nahaja Nemčija in kje Slovenija. V uvodu smo navedli razloge za izbiro Nemčije, kot neke reference.

Na podlagi javno dostopnih podatkov torej poglejmo, koliko bi bila na trgu vredna električna energija OVE, če bi za vse nove OVE elektrarne ta trenutek ukinili njihov privilegirani položaj na trgu z električno energijo in bi bile te po logiki iz Slike 3 povsem izenačene s "klasičnimi" viri. Kot rečeno smo v analizi upoštevali zadnjo leto in pol dogajanja na nemški in slovenski borzi z električno energijo.

Kljub dobri dostopnosti do podatkov [2, 3], je bilo treba nekatere faktorje privzeti. Zlasti to velja za podatke proizvodnje slovenskih SE. Pred leti so na strani ELES, kjer prikazujejo trenutne in historične podatke o proizvodnji in porabi [9] podajali tudi proizvodnjo SE, vendar so to kasneje ukinili. Pridobivanje teh podatkov namreč ni preprosto. Če je veliko SE na nizki napetosti (hišne SE), bi bilo potrebno sprotno zbirati podatke za vsako gospodinjstvo s SE posebej. Zbiranje podatkov na nivoju nizkonapetostnega izvoda ali celo na srednji napetostni strani namreč ne pove mnogo, saj ni mogoče gotovo ločiti med visoko proizvodnjo SE in hkratno visoko porabo ter nizko proizvodnjo SE in hkratno nizko porabo. Podoben problem velja za lastnike SE s tako imenovanim net-meteringom.

Na omenjeni ELES-ovi strani imajo za podatke proizvodnje SE v Sloveniji preusmeritev na ustrezno stran Entso-e [10] in uporabljeni podatki izvirajo od tam. Borzne cene smo povzeli po [11], podatke o količini instaliranih SE v Sloveniji pa po [12] in [13].

Pri analizi podatkov pa sta se pojavila dva problema. Prvi je bil ta, da so bili nam dostopni podatki o instalirani moči sončnih elektrarn samo za trenutek ob koncu leta. Za natančne izračune, koliko je v bistvu celoten sistem SE izkoriščen, bi potrebovali ta podatek za vsako uro. Ker je bil prirast instalirane moči SE leta 2023 v Sloveniji izjemno visok (več od 400 MW - od manj od 700 MW na več, kot 1100 MW), tudi povprečna vrednost ne bi dala sprejemljivih rezultatov. Razen tega (med analizo) ni bilo mogoče najti podatka o instalirani moči elektrarn na polovici leta 2024. Zato smo privzeli linearno rast instalirane moči SE skozi časovni točki 31. 12. 2022 in 31. 12. 2023 za celotno študirano obdobje. Kasneje je ELES v sporočilu za javnost [14] objavil, da bo uvedel na svoji spletni strani tudi sprotno spremljanje proizvodnje in količine obnovljivih virov v Sloveniji. Na žalost za naše obravnavano obdobje to ne pomaga veliko, smo pa imeli priložnost narediti preizkus za eno časovno točko in primerjati ELES-ove nove podatke z našimi predpostavljenimi (ekstrapolacija v letu 2024). Izkazalo se je, da so se skoraj povsem skladajo. To sicer ni dokaz, je pa dober indic, da so naše predpostavke blizu dejanskemu stanju, če zaupamo ELES-ovi oceni trenutnega dejanskega stanja.

Drug problem so predstavljali podatki o urni proizvodnji slovenskih SE na strani Entso-e. Pri analizi se je namreč izkazalo, da je skupna letna proizvodnja (preprost seštevek urnih podatkov) veliko manjša, kot bi jo pričakovali iz podatkov o instalirani moči SE glede na nek tipičen faktor izkoriščenosti (kot rečeno okrog 10 %) in tudi bistveno manjša od podatka na [12]. Špekuliramo lahko, da je slovenski operater pošiljal Entso-e le podatke, do katerih je imel dostop (nekaj več kot polovica ocenjene dejanske energije SE). Zato smo urne podatke o proizvodnji SE v Sloveniji normirali tako, da je na koncu leta bila energija enaka objavljeni letni proizvodnji [12]. Tak pristop je smiseln, ker dejanski poslani podatki, čeprav niso kompletni, podajo časovno razporeditev proizvodnje, z drugimi besedami, kakor je osončena polovica SE, približno tako je po vsej verjetnosti osončena tudi druga polovica. V prejšnjem odstavku omenjeni test je to predpostavko povsem potrdil.

Menimo, da je nekoliko daljši uvod s pojasnilom glede uporabljenih podatkov nujen, ker leži izvirni greh množice študij in prispevkov (zlasti na področju tako imenovane podnebne politike in energetike, ki "dokazujejo" potrebo po neskončnem plačevanju t. i. zelenega prehoda) v prirejenih ali selekcioniranih podatkih (Dokazov in analiz na to temo je veliko, a zaradi nebistvenosti referenc na tem mestu ne navajamo). V nadaljevanju torej poglejmo, kaj so pokazali izračuni.

3.1 Situacija v Nemčiji

Izračuni za leto 2023 in prvo polovico leta 2024 za razmere v Nemčiji so predstavljeni v nadaljevanju.

Tabela 1: izračuni za Nemčijo

Izračunana vrednost ↓ / Leto →	2023	2024
Povprečna cena na borzi [€/MWh]	95	68
Povprečen zaslužek 1 MW VE na uro [€/h]	19,4	14,6
Povprečen zaslužek 1 MW SE na uro [€/h]	6,7	4,3
Vrednost proizvodnje VE glede na povprečno ceno na borzi [%]	85	87
Vrednost proizvodnje SE glede na povprečno ceno na borzi [%]	77	64
Delež VE v proizvodnji D [%]	32	29
Delež SE v proizvodnji D [%]	12	13
Strošek redispatchinga [Mrd €]	2,35	1,175*
Vrednost proizvodnje VE obremenjene za delež redispatchinga na instalirano moč** glede na povprečno ceno na borzi [%]	63	60
Vrednost proizvodnje SE obremenjene za delež redispatchinga na instalirano moč** glede na povprečno ceno na borzi [%]	54	37

* - privzeto

** - v Nemčiji konkretno delitev med VE in SE ca. pol – pol.

Preurejanje predhodno dogovorjene proizvodnje (redispatching) lahko v veliki meri pripišemo volatilnosti proizvodnje OVE. Seveda podatkov, kdo je za posamezen primer "odgovoren" ni in tega velikokrat niti ni moč nedvoumno ugotoviti. Menimo, da razdelitev med VE in SE glede na njihovo instalirano moč predstavlja sprejemljiv kompromis, ki poda vsaj dobro oceno za ta del stroškov implementacije OVE v EES.

3.2 Situacija v Sloveniji

Adekvatno izračunom za Nemčijo smo izvedli te tudi za Slovenijo. Osnovna razlika med naboroma je v tem, da v Sloveniji nismo upoštevali VE, ker je njihov delež zanemarljiv.

Tabela 2: izračuni za Slovenijo

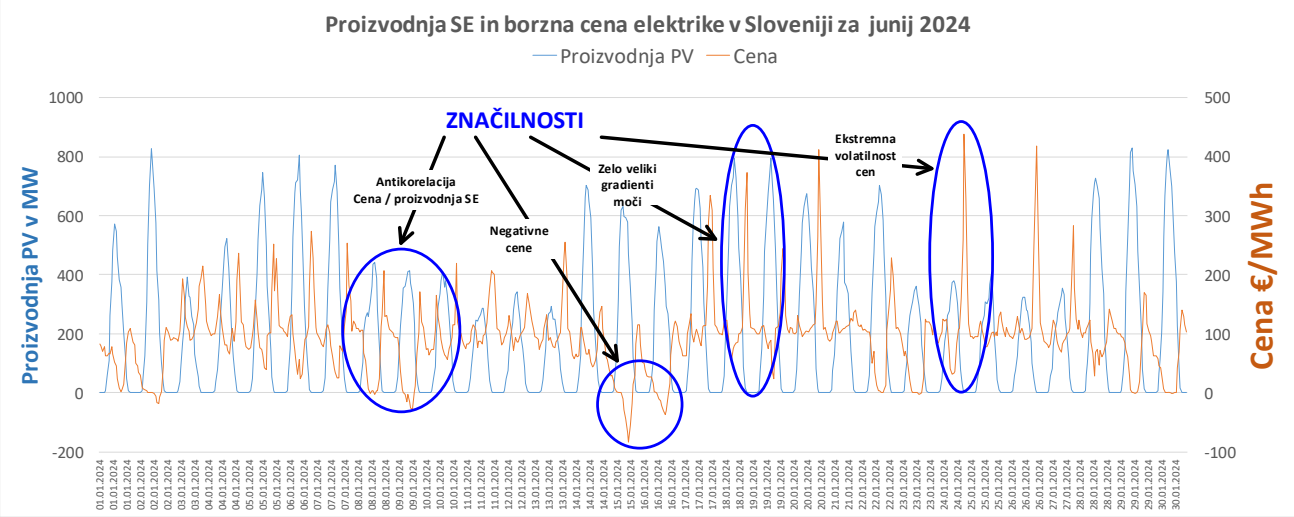
Izračunana vrednost ↓ / Leto →	2023	2024
Povprečna cena na borzi [€/MWh]	104	73
Povprečen zaslužek 1 MW SE na uro [€/h]	6,6	5,1
Vrednost proizvodnje SE glede na povprečno ceno na borzi [%]	83	70
Delež SE v proizvodnji RS [%]	4,6	7,7

Poglejmo, kaj nam povedo navedene številke.

3.3 Diskusija

Preden začnemo z interpretacijo rezultatov velja omeniti, da pri analizi nemških in slovenskih razmer v EES (proizvodnja, poraba) in dogajanja na ustreznih borzah [1, 11] ne gre za dva različna EES, temveč za en povezan EES in dve različni področji. Različne borzne cene nastajajo le zaradi omejenih možnosti prenosa energije. Ker sta obe področji vpeti v skupen sistem (Entso-e), se sistemski učinki OVE na obravnavanih področjih ne odražajo na borzne cene enako, kot bi se, če bi imeli opravka z električnima otokoma. Vpliv je "mehkejši", ker se različna področja do neke mere dopolnjujejo in tudi o tem govorimo, ko izpostavljamo prednosti povezave v velik EES.

Neglede na to pa je možno potegniti vzporednice med predstavljenimi ekonomskimi izračuni iz literature (Slike 4, 5, 6) in med obravnavanima deloma Entso-e. V Nemčiji je vrednost elektrike iz OVE (zmanjšana za ca. 15 % pri VE in med 40 % in 50 % povprečne cene pri SE – ne pozabimo faktor vrednosti za VE se začne pri ca. 100 % in za SE pri ca. 130 % Glej Sliko 5), tudi ob upoštevanju redispatchinga (zmanjšanje za ca. 40 % pri VE in za ca 60 % pri SE), nekoliko višja, kakor bi sklepali recimo iz Slike 6. Razliko lahko pripišemo omenjenemu "omehčanju" kanibalskega učinka zaradi možnosti izmenjave energije z drugimi področji. Električna okolica Nemčije namreč po prispevku OVE za njo zaostaja in blaži omenjeni učinek.



Slika 7: Učinek proizvodnje SE na borzo "Southpool" Vir: lastni izračuni

V Sloveniji je prispevek OVE med 5 in 10 x manjši, kakor v Nemčiji, zato je smiselno primerjati rezultate s tistimi na Sliki 5. Izkaže se, da je kanibalski učinek v Sloveniji (zmanjšanje vrednosti za reda 50 % povprečne cene – zopet ne pozabimo, primerjalna vrednost je 130%) precej večji od tistega, ki bi ga razbrali iz Slike 5, se pa precej dobro sklada s Sliko 6. Sklepamo lahko, da je v električni okolici Slovenije odstotek proizvodnje iz SE večji, kakor v Sloveniji, kar pomeni, da Slovenija v bistvu "uvaža" kanibalski učinek SE, saj je relativno majhen trg. Omenjeno dejstvo do neke mere potrjuje dogajanje na borzi "Southpool". Močna volatilnost cene (nihanje, skoki) namreč ne morejo biti povzročeni z nihanjem proizvodnje le slovenskih SE – glej Sliko 7 – so pa kvalitativno gledano razmere identične dogajanju na drugih (recimo nemški) borzah.

4 SKLEP

"Veter in sonce sta zastonj!" je krilatica, ki jo pogosto slišimo bodisi bodi si od ljudi, ki ne vedo veliko o realnosti, bodisi od tistih, ki namerno zavajajo. Resnica skoraj ne bi mogla biti bolj drugačna. V [1] smo pokazali, kaj vgradnja OVE (recimo SE in/ali VE) dejansko "potegne za sabo" in kake indirektne stroške povzroči v EES.

V tem prispevku pa nas je zanimalo, koliko je resnična tržna cena elektrike iz OVE (SE in VE) v Nemčiji in Sloveniji. Teh podatkov namreč v javnosti ni zaslediti, saj ne skladajo z uradno politiko "zelenega prehoda". Njihovo objavljanje je torej "politično nezaželeno."

Analizirali smo zadnje leto in pol dogajanja v Nemčiji in Sloveniji. Zakaj poleg Slovenije še Nemčijo in zakaj to obdobje pojasnimo v Uvodu. Zaradi narave proizvodnje iz OVE, lastnosti obratovanja EES in značilnosti porabnikov prihaja z naraščanjem deleža proizvodnje iz OVE do tako imenovanega kanibalskega učinka na trgu z električno energijo. To pomeni, da po eni strani OVE sami sebi zbijajo tržno ceno elektrike in po drugi strani ekonomsko onemogočajo najboljše elektrarne (dobre premogovne elektrarne z visokim izkoristkom, neamortizirane jedrske elektrarne in plinsko-parne elektrarne z visokim izkoristkom). Prvo dejstvo za same OVE niti ni tako tragično, saj ekonomsko preživijo s subvencijami in/ali privilegiranim položajem. Bankrot in zapiranje (in seveda ustavitev gradnje česarkoli, kar ni subvencionirano, razen poceni plinskih elektrarn z odprtim ciklom, slabim izkoristkom in zelo drago elektriko) omenjenih klasičnih elektrarn pa lahko obratovanje EES pripelje v nemogočo situacijo, cene elektrike na borzi pa do nepredstavljivih skokov.

Izkazalo se je, da je s kanibalskim učinkom povezano relativno znižanje cene VE v Nemčiji nekje 15 %, SE pa za ca. 50 % povprečne tržne cene. Če omenjenim VE in SE "naprtimo" še stroške "redispatchinga", se ti številki povečata na ca. 40 oz. 90 %. Glede na ekonomske izračune v literaturi jo OVE v Nemčiji zaradi podpore sosednjih sistemov (beri: "parazitiranja" nemškega) še dobro odnesejo.

Za razliko od nemškega je situacija v Sloveniji nekoliko slabša, kot bi pričakovali glede na literaturo. Cena energije SE je za več kot 50 % povprečne borzne cene nižja od tiste, ki bi jo pričakovali, če bi v EES bilo le malo SE (pade iz 130 % na 70 % povprečne borzne cene). Kanibalski učinek Slovenija v bistvu "uvaža" in elektrika iz njenih SE je na trgu še manj vredna, kakor bi pričakovali "iz teorije". V razmerah, kjer bi bili akterji na trgu izenačeni, ne bi imele nove SE nobene možnosti ekonomskega preživetja. In to, brez da bi jim "naprtili" stroške "redispatchinga", kaj šele morebitnih shranjevalnikov.

In nauk zgodbe? Morda bi krilatico "Veter in sonce sta zastonj!" veljalo zamenjati z: "Veter in sonce kmalu ne bosta vredna nič." Pa še retorično vprašanje: "Kdo bo vse to plačal?"

ZAKAJ ŽE, PRAVZAPRAV ???

Kako razumeti ogljični odtis?

prof. dr. Gregor Radonjič
University of Maribor
Faculty of Economics and Business
Dept. of technology and environment protection
gregor.radonjic@um.si

Povzetek

Ogljični odtis, ki pomeni vsoto neposredno in posredno povzročenih emisij toplogrednih plinov s strani organizacije, izdelka, storitve, dogodka ali posameznika je postal eden od najpomembnejših okoljskih indikatorjev oz. indikatorjev trajnostnosti. Kljub njegovi popularnosti in razširjeni uporabi pa je ogljični odtis povezan z različnimi metodološkimi ter konceptualnimi pomanjkljivostmi. Predvsem je preveliko osredotočanje na ogljični odtis v majhni državi kot je Slovenija, ki v bilanco emisij toplogrednih plinov prispeva minorni delež v primerjavi z velikimi državami, problematično zato, ker se posledično pozablja na nekatere ključne okoljevarstvene probleme, ki so vitalnega pomena za kakovost življenja oz. bivanja.

Ključne besede

ogljični odtis, toplogredni plini, metoda LCA

1 Uvod

Emisije toplogrednih plinov (TGP) veljajo v splošnem v gospodarstvu in politiki za ključni okoljski problem in prioriteto, o katerem se v primerjavi z drugimi okoljskimi problemi neproporcionalno več razpravlja ter se mu namenja medijskega in političnega prostora. Pojmi kot so nizko- in brezogljična družba, nizko- in brezogljično gospodarstvo, razogljičenje, ogljična nevtralnost ter z njimi povezani ukrepi so v vrhu prioritet vladnih ukrepov in trajnostnih politik podjetij [1-3]. Za določene organizacije oz. podjetja je poročanje o emisijah TGP postalo tudi obvezno [4]. Za upravljanje 'ogljičnih politik' so zato potrebni kvantitativni podatki o emisijah TGP, s pomočjo katerih se spremlja tako trenutno stanje glede emisij TGP kot tudi učinkovitost ukrepov v zvezi z njihovim zmanjševanjem. Vlogo takšnega kvantitativnega indikatorja je prevzel ogljični odtis, ki predstavlja glavni kvantitativni indikator za izvajanje in spremljanje podnebnih politik (predvsem zmanjševanja emisij CO_2), tako na nivoju podjetij kot tudi občinskih ter državnih ustanov.

Namen prispevka je prikazati nekatere vidike v povezavi z ogljičnim odtisom (s poudarkom na ogljičnem odtisu izdelkov), ki so praviloma spregledani oz. neupoštevani v gospodarski praksi in družbenih diskusijah ter opozoriti na njegove metodološke in konceptualne pomanjkljivosti.

2 Metodološke in konceptualne pomanjkljivosti ogljičnega odtisa

Ogljični odtis ima pomembne metodološke in konceptualne pomanjkljivosti pri ugotavljanju dejanskih vplivov izdelkov, storitev in podjetij na okolje [5-6]. Gospodarsko, politično in medijsko osredotočanje izključno na ogljični odtis namreč daje zavajajoč občutek glede celovitih vplivov izdelkov, storitev in organizacij na okolje, saj se pozablja na številne druge vplive, ki jih povzročajo podjetja oz. njihovi izdelki ali storitve [7-9]. Posledica tega je, da predstavniki gospodarstva pogosto zgled za svojo "zeleno" naravnanost prikazujejo izključno z osredotočanjem na zmanjšanje ogljičnega odtisa, pri tem pa kot po pravilu pozabljajo na številne druge vplive na okolje (ali pa se jih sploh ne zavedajo), ki so prav tako posledica njihove dejavnosti ali proizvodnje ter uporabe izdelkov [10]. Ob tem velja poudariti, da poleg ogljičnega odtisa obstaja še več pomembnih "odtisov", kot sta na primer vodni in ekološki odtis, za katera velja, da nikakor ne bi smela biti v senci ogljičnega odtisa.

Poleg omenjenih konceptualnih pomanjkljivosti ogljičnega odtisa ne gre spregledati tudi številnih metodoloških pomanjkljivosti njegovega določevanja. Še posebej je ta problem prisoten pri določevanju ogljičnega odtisa izdelkov zaradi njihovih kompleksnih okoljskih življenjskih ciklov. Takšno določevanje ni enostavno, saj mora temeljiti na njihovih velikokrat kompleksnih okoljskih življenjskih ciklih. Le-ti vključujejo številne faze: pridobivanje surovin za materialno in energijsko proizvodnjo, transport, proizvodnjo materialov, kemikalij, sestavnih delov, embalaže, proizvodnjo končnih izdelkov, vplive med uporabo ter pri ravnanju z odpadki.
Metodološke pomanjkljivosti določevanja ogljičnih odtisov izdelkov, li lahko močno vplivajo na končno vrednost ogljičnega odtisa, tako zajemajo upoštevanje različnih meja življenjskih ciklov, vpliv energijskih mešanic različnih držav, dostopnost do verodostojnih podatkov o emisijah TGP v fazah pridobivanja

surovin in tehnoloških postopkov ravnanja z odpadki, izbor pravilnih emisijskih faktorjev ter potencialov globalnega segrevanja (GWP koeficienti) in upoštevanje oz. izvzetje biogenega CO_2 v izračunih [6]. Vse to lahko vodi do neprimerljivosti vrednosti ogljičnih odtisov. Rezultati so torej odvisni od številnih spremenljivk in predpostavk, a tudi poenostavitev, kar praviloma onemogoča neposredno primerjavo rezultatov izračunov in posledično otežuje pravilno komunikacijo z javnostjo [11-12].

Kljub omenjenim metodološkim in konceptualnim pomanjkljivostim sedanji koncept ogljičnega odtisa že pomeni osnovo za nove zakonodajne ter administrativne ukrepe v gospodarstvu (politične zahteve po ogljični nevtralnosti, obdavčitve, poročanje). Pojavljajo pa se tudi konkretni predlogi, da bi sedanji koncept ogljičnega odtisa morebiti uporabil kot mehanizem dodatnega pritiska oz. kontrole državljanov v okviru ideje o določitvi ogljičnih kreditov posameznika (kreditnih točk) kot del ideje o socialnem točkovanju obnašanja oz. aktivnosti ljudi v povezavi z neposredno in posredno povzročenimi emisijami CO_2 [13-15]. In to ne glede na dejstvo, da odstotek globalne elite s svojimi poslovnimi odločitvami ter načinom življenja povzroča vrtoglave količine emisij TGP [16]. Medsebojni preplet omenjenih vidikov shematsko prikazuje slika 1.

Slika 1: Ogljični odtis – preplet različnih vidikov za njegovo razumevanje

3 Metoda LCA – alternative ogljičnemu odtisu

Zaradi omenjenih metodoloških in konceptualnih pomanjkljivosti se je potrebno v takih primerih poslužiti drugih, celovitejših metod vplivov izdelkov, storitev ali organizacij na okolje kot je npr. metoda LCA ('Life Cycle Assessment'). S to kompleksno analitsko metodo določamo vplive izdelkov v njihovih celotnih okoljskih življenjskih ciklih, ki zajemajo pridobivanje surovin, pridobivanje energijskih virov, proizvodnjo in distribucijo potrebne energije, proizvodnjo polizdelkov, izdelkov ter stranskih izdelkov, transport in distribucijo, učinke med uporabo in alternativne možnosti ravnanja z izdelki po uporabi. Vključuje vse snovne in energijske tokove, tudi take, ki bi bili z uporabo drugih metod lahko prezrti. V obravnavanje življenjskega okoljskega cikla nekega proizvoda je vedno vključeno tudi pridobivanje energije, potrebne za pridobivanje surovin, za njegovo predelavo, proizvodnjo, transport, distribucijo, uporabo itn., ki se prične prav tako s pridobivanjem potrebnih energijskih virov. Vendar z metodo LCA masne in energijske vtoke ter iztoke ne le kvantificiramo, ampak jih povežemo z njihovim dejanskim škodljivim učinkom na okolje ter zdravje. LCA analiza lahko vključuje tudi do 20 različnih okoljskih kategorij, kot so npr. ogljični odtis, razgradnja ozonskega sloja, kisli dež, evtrofikacija, emisije trdnih delcev, ekotoksičnost, raba vode, izčrpavanje mineralnih surovin idr. Kar je posebej pomembno, je dejstvo, da so za ovrednotenje oz. preračun vplivov emisij in drugih snovi na okolje ter zdravje uporabljeni najnovejši in znanstveno podprti modeli, kar daje metodi LCA dodatno veljavo glede verodostojnosti rezultatov. Zato s pomočjo metode LCA podjetja ne pridobijo le podatkov, kakšni so vplivi v posameznih fazah življenjskih ciklov, ampak tudi podatke o vplivih na okolje, ki se jih z drugimi metodami ne da določiti.

Ker metoda LCA temelji na okoljskem življenjskem ciklu, se lahko s celostnim pristopom obravnavanja vplivov proizvoda na okolje v večji meri zagotovi, da se identificirajo najbolj relevantni vplivi na okolje v celotnem proizvodno-distribucijskem sistemu in ne nazadnje, da se prepreči, da bi se okoljski vplivi "prestavljali" iz ene faze življenjskega cikla v drugo in obratno (npr. pri menjavi materalov, sestavnih delov, energentov idr.), saj lahko spremembe z izračunom preverimo vnaprej. Poudariti velja, da je metoda LCA edina mednarodno standardizirana metoda za ovrednotenje vplivov izdelkov na okolje, njen metodološki okvir pa definirajo mednarodni standardi družine ISO 14040 [17].

Ogljični odtis je vselej del LCA analiz, kar pomeni, da ima določevanje vplivov izdelkov in storitev na okolje s pomočjo LCA metode številne prednosti pred določevanjem samo ogljičnega odtisa, kar žal počnejo slovenska podjetja in v kar jih z zakonskimi in podzakonskimi akti sili politika. Ogljični odtis izdelka dobi v okviru LCA analiz povsem drugo perspektivo, saj ga primerjamo z ostalimi okoljskimi indikatorji oz. vplivi na okolje. In prav analize LCA nam dokazujejo, da ogljični odtis ni vedno nujno najbolj vplivni okoljski indikatorji v življenjskih ciklih izdelkov v primerjavi z drugimi okoljskimi indikatorji [9,18]. Če se upošteva celotni okoljski življenjski cikel izdelkov in ne le faza uporabe, se tudi zelo spremenijo okoljski profili e-vozil ter tehnologij za pridobivanje energije iz obnovljivih virov (na primer biogoriv) [19] ali solarnih panelov [20].

A vendarle se je potrebno zavedati, da imajo tudi programska orodja, s katerimi modeliramo življenjske cikle v okviru LCA analiz, vgrajene določene modelne spremenljivke ter poenostavitve, s čimer je možno vplivati na končne rezultate, zato takšne študije zahtevajo izkušene in poštene izvajalce, ki uporabljajo najsodobnejšo programsko opremo ter podatkovne baze.

Zaradi vsega navedenega je lahko uporaba izključno ogljičnega odtisa v promocijske namene tudi sredstvo okoljskega zavajanja

(t.i. "greenwashing") (ANEC/BEUC/ECOS/EEB, 2009; Radonjič, 2016).

4 Zaključek

Za Slovenijo je velika popularnost ogljičnega odtisa in intenzivno osredotočanje politike, medijev ter gospodarstva nanj problematično tudi zato, ker bi tudi v primeru popolne ogljične nevtralnosti države to predstavljalo le minoren prispevek h globalni bilanci toplogrednih plinov (še posebej, če k temu prištejemo enormne emisije ogljikovega dioksida ter mnogih škodljivih plinov in delcev zaradi vojaških aktivnosti v svetu) ob istočasnem ignoriranju ali vsaj manjši pozornosti okoljskih problemov, ki pa jih resnično lahko in moramo sami obvladovati, ker neposredno vplivajo na kakovost okolja in zdravja v Sloveniji. S tem je mišljen predvsem odnos do naših sladkih in morskih voda, do uporabe kemikalij v kmetijstvu, izpostavljenosti kemikalijam v izdelkih, varovanje rodovitnih kmetijskih površin, odnos do gozdov, učinkovito ravnanje z odpadki in zmanjševanje tistih izpustov v zrak, ki imajo lokalne ali regionalne škodljive učinke, bodisi zaradi lokalne industrijske proizvodnje, bodisi zaradi transporta. Razumeti ogljični odtis v okviru okoljskih politik zato pomeni razumeti tako njegove metodološke kot konceptualne pomanjkljivosti.

Ali je prispevek slovenske živinoreje k podnebnim spremembam precenjen?

Is the contribution of Slovenian livestock farming to climate change overestimated?

Jože Verbič
Oddelek za živinorejo
Kmetijski inštitut Slovenije
Ljubljana, Slovenija
joze.verbic@kis.si.com

POVZETEK

Za živinorejo so značilni veliki izpusti metana. Metan uvrščamo med kratko obstojne toplogredne pline. Za razliko od CO_2, ki se v ozračju zadrži več stoletij, se metan po navedbah zadnjega (šestega) ocenjevalnega poročila Medvladnega odbora za podnebne spremembe (IPCC) oksidira v približno 12 letih. Za poročanje Okvirni konvenciji Združenih narodov o spremembi podnebja (UNFCCC) uporabljamo metodo potencialnega globalnega segrevanja za stoletni časovni horizont (GWP_{100}). V zadnjem času se vse pogosteje pojavljajo kritike, da metoda GWP_{100} ni najbolj primerna za oceno kumulativnega učinka trajnih izpustov kratko obstojnih plinov na podnebje. Raziskovalci so razvili metodo, ki upošteva lastnosti kratko obstojnih onesnaževal zraka (GWP*). Za to metodo je značilno, da bolje napoveduje odziv temperature zemeljskega površja na izpuste kratko obstojnih plinov kot GWP_{100}. S primerjavo obeh metod je bilo ugotovljeno, da metoda GWP_{100} precenjuje prispevek slovenske živinoreje k segrevanju podnebja za 4,6 krat.

KLJUČNE BESEDE

podnebne spremembe, živinoreja, metan

ABSTRACT

Livestock farming is characterized by high methane emissions. Methane is classified as a short-lived greenhouse gas. Unlike CO_2, which remains in the atmosphere for centuries, methane oxidizes in about 12 years, according to the latest (sixth) assessment report of the Intergovernmental Panel on Climate Change (IPCC). For reporting to the United Nations Framework Convention on Climate Change (UNFCCC), we use the 100-year global warming potential (GWP_{100}) method. Recently, there has been increasing criticism that the GWP_{100} method is not the most appropriate method to assess the cumulative impact of persistent emissions of short-lived gasses on the climate. Researchers have developed a method that takes into account the characteristics of short-lived air pollutants (GWP*). This method is characterized by a better prediction of the response of the Earth's surface temperature to emissions of short-lived gasses than GWP_{100}. When comparing the two methods, it was found that the GWP_{100} method overestimates the contribution of Slovenian livestock farming to climate warming by a factor of 4.6.

1 UVOD

V javnosti je splošno razširjeno mnenje, da je intenzivna evropska intenzivna živinoreja med najpomembnejšimi vzroki podnebnih sprememb. K temu je veliko prispevalo FAO poročilo Dolga senca živinoreje (Livestock's long shadow) [1]. Najpogosteje izpostavljeno sporočilo, ki so ga mediji posredovali javnosti je, da je živinoreja glavni povzročitelj izpustov toplogrednih plinov (TGP) in da je odgovorna za 18 % izpustov, kar presega izpuste iz prometa. Ob tem sporočilu so bile izražene kritike intenzivne evropske živinoreje, zamolčano pa dejstvo, da se struktura izpustov TGP v Evropi precej razlikuje od izpustov na globalni ravni, saj je raba fosilnih goriv v prometu, industriji in v gospodinjstvih nadpovprečna, število živine pa razmeroma majhno. Zamolčan je bil podatek istega poročila [1], da je prispevek Zahodne Evrope in Severne Amerike k skupnim (globalnim) izpustom metana iz prebavil rejnih živali le nekaj več kot desetina (10,75 %). Le malokdo se zaveda, da je število goved v Afriki (189,6 milijonov) približno dvakrat večje kot v Evropi (celina) (92,1 milijonov, v glavah velike živine) [2].

Za živinorejo so značilni veliki izpusti ne-CO_2 toplogrednih plinov, predvsem metana. Različni toplogredni plini se v njihovem učinku na segrevanje podnebja razlikujejo. Za namene poročanja o emisijah TGP jih preračunamo v ekvivalente (ekv) ogljikovega dioksida z upoštevanjem potenciala globalnega segrevanja za stoletni časovni horizont (Global Warming Potential, GWP_{100}). Po tej metodi je slovenska živinoreja po zadnjih podatkih (za leto 2022) prispevala 8,35 % vseh emisij TGP v Sloveniji. K temu so

največ prispevali izpusti metana iz prebavil (6,31 %), sledili so izpusti metana iz skladišč za živinska gnojila (1,61 %), izpusti didušikovega oksida iz skladišč za živinska gnojila (0,27 %) in posredni izpusti didušikovega oksida, ki nastanejo zaradi uhajanja dušikovih spojin iz hlevov in skladišč za živinska gnojila [3]. K izpustom v živinoreji je največ prispevala govedoreja (92,7 %), sledile so reja prašičev (2,6 %), perutnine (1,6 %), ovc (1,7 %), koz (0,3 %), konj (0,9 %) in kuncev (manj kot 0,1 %) [3].

Ocenjevanje vpliva človekovih dejavnosti na spremembe podnebja na podlagi GWP_{100} sega v obdobje prvega poročila Medvladnega odbora za podnebne spremembe, ki je bilo izdano v letu 1990. Že ob uveljavitvi tega koncepta je bilo prepoznano, da ima ob prednostih (t.j. predvsem enostavna implementacija), tudi resne pomanjkljivosti [4]. Od metode za postavitev različnih TGP na skupni imenovalec pričakujemo predvsem, da bo realno ocenila učinek izpustov teh plinov na spremembe temperature zemeljskega površja. Smith in sod. [5] so opozorili, da koncept GWP_{100} slabo oceni odziv temperature na kumulativne izpuste kratko obstojnih toplogrednih plinov, med katerimi je tudi metan. Za razliko od CO_2, ki ostane v ozračju več stoletij, se metan relativno hitro oksidira (približno 12 let) [6]. Koncept GWP_{100} tega ne upošteva. Za realnejšo oceno vpliva izpustov metana na podnebje so raziskovalci nedavno razvili nov način za preračun izpustov različnih toplogrednih plinov na skupni imenovalec, ki upoštevajo, da je metan v atmosferi kratko obstojen (GWP*) [7, 8, 9].

Za dolgo obstojne TGP je značilno, da se v ozračju akumulirajo. Vsak enkratni izpust (npr. izpust v tekočem letu) poveča koncentracijo plina v ozračju in četudi takoj prenehamo z novimi izpusti, se koncentracije tega plina ne bodo zmanjšale. Vsak enkratni izpust dolgo obstojnega TGP pomeni dodatno segrevanje, ki ga je treba prišteti k učinku vseh izpustov tega plina v zgodovini. Pri metanu je drugače. Koncentracija v ozračju ni odvisna le od izpustov v tekočem letu, ampak tudi od obsega oksidacije metana, ki smo ga v ozračje izpustili v preteklosti. V ozračju se sproti vzpostavlja novo ravnovesje. Če letne izpuste ohranjamo na ravni iz preteklosti, se koncentracije ne spreminjajo. Če letne izpuste povečujemo, se povečujejo tudi koncentracije v ozračju in če jih zmanjšujemo se koncentracije zmanjšajo. GWP* to upošteva in je razmeroma dober približek podnebnemu modelu. Na drugi strani pa GWP_{100} v primeru vzdržnih ali padajočih izpustov metana prikriva napredek proti podnebnemu cilju, ki ga Pariški sporazum določa v °C glede na predindustrijsko dobo [10].

Problematika ocenjevanja izpustov metana na podnebje je bolj obsežno in poglobljeno obravnavana v zadnjem (šestem) ocenjevalnem poročilu Medvladnega odbora za podnebne spremembe. Ugotavljajo, da metoda GWP_{100}, ki jo uporabljamo za poročanje Okvirni konvenciji Združenih narodov o spremembi podnebja (UNFCCC), ni najbolj primerna za oceno kumulativnega učinka trajnih izpustov kratko obstojnih plinov na podnebje [11]. Medvladni odbor v zadnjem poročilu ni priporočil nobene od obravnavanih metodik za preračun izpustov različnih TGP na skupni imenovalec [6]. Zapisali so, da je izbor najprimernejše metrike odvisen od namena primerjave. Na 27. Konferenci pogodbenic Okvirne konvencije Združenih narodov o spremembi podnebja v Sharm El–Sheikhu je bilo izglasovano, da lahko pogodbenice ob GWP_{100} dodatno poročajo tudi na podlagi alternativnih metod, kot je GWP* [12].

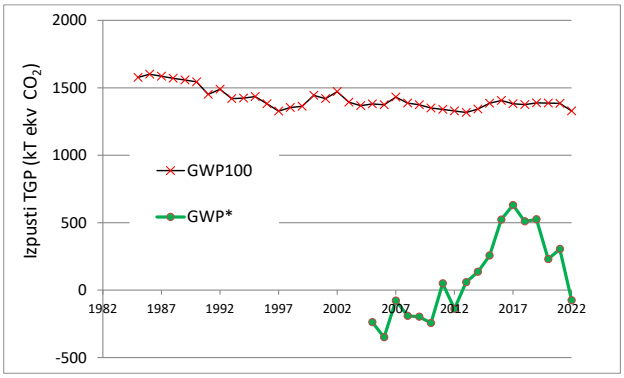
Namen tega prispevka je prikazati, kakšen je prispevek slovenske živinoreje k izpustom toplogrednih plinov, če le tega ocenimo z metodo, ki upošteva obstojnost metana v ozračju (GWP*). Rezultate smo primerjali z rezultati po metodi, ki je splošno uveljavljena za poročanje UNFCCC (GWP_{100}).

2 METODE

Podatke o izpustih metana in didušikovega oksida za obdobje 1985-2022 smo zajeli iz emisijskih evidenc Kmetijskega inštituta Slovenije [3]. Gre za izvorne podatke, ki so uporabljeni za poročanje UNFCCC [13]. Za živinorejo smo upoštevali izpuste metana iz prebavil rejnih živali, izpuste metana iz skladišč za živinska gnojila, izpuste didušikovega oksida iz skladišč za živinska gnojila in posredne izpuste didušikovega oksida, ki nastanejo zaradi uhajanja dušikovih spojin iz hlevov in skladišč za živinska gnojila. Podatki o izpustih metana in didušikovega oksida so bili preračunani v ekvivalente CO_2 ob upoštevanju potencialov globalnega segrevanja za stoletno časovno obdobje (GWP_{100}), kot je trenutno v veljavi za poročanje UNFCCC (faktor 28 za metan in faktor 265 za didušikov oksid). Podatke o izpustih TGP iz živinoreje smo preračunali v ekvivalente CO_2 tudi z alternativno metodo GWP*. Pri tem smo za didušikov oksid uporabili enak postopek kot za GWP_{100}, za metan pa metodo po Cain in sod. [7].

3 REZULTATI IN RAZPRAVA

Podatki o izpustih TGP v slovenski živinoreji so predstavljeni na Grafu 1. Za GWP_{100} razpolagamo s podatki za obdobje 1985-2022. Za GWP* razpolagamo le s podatki po letu 2005. Ker je ocena po GWP* odvisna tudi od preteklih izpustov, podatkov pred tem letom ni mogoče izračunati. Primerjava kaže, da je prispevek slovenske živinoreje k podnebnim spremembam z metodo GWP_{100} zelo precenjen. V obdobju 2005-2022 so se izpusti gibali od 1318 do 1432 kT ekv CO_2. Po metodi GWP* smo imeli v znatnem delu tega obdobja negativne izpuste (obdobje 2005-2010, 2012, 2022). Za leta z negativnimi izpusti je bilo ocenjeno, da je obseg oksidacije metana iz preteklih izpustov presegel izpuste iz tega leta in da je razlika izničila tudi izpuste didušikovega oksida. Povprečje za obdobje 2018-2022 kaže, da metoda GWP_{100} precenjuje prispevek slovenske živinoreje k segrevanju podnebja za 4,6 krat (izpusti po GWP_{100} in GWP* so bili v povprečju 1373 in 299 kT ekv CO_2 na leto). Metoda preračunavanja posameznih TGP zelo vpliva tudi na strukturo izpustov. Po metodi GWP_{100} je prispevek slovenske živinoreje k skupnim izpustom (vsi sektorji) ocenjen na 8,33 %, po GWP* pa na 2,40 % (ocena za obdobje 2018-2022, pri čemer so bili pri skupnih izpustih za GWP* korigirani tudi izpusti metana iz drugih sektorjev). Vedeti moramo, da k ugodnemu rezultatu za živinorejo po GWP* prispeva predvsem razmeroma uspešno zmanjševanje izpustov metana v preteklem obdobju. V primeru hitrega povečevanja izpustov namreč ocene po GWP* presegajo ocene po GWP_{100}. V Sloveniji na to kaže primer reje drobnice, kjer so bili v obdobju 2005-2015 izpusti po GWP* dva do trikrat večji kot po GWP_{100} [14].



Graf 1: Primerjava metod GWP_{100} in GWP* za preračun izpustov toplogrednih plinov v slovenski živinoreji v ekvivalente CO_2. Prikaz zajema tako izpuste metana kot didušikovega oksida.

Nov način obračunavanja toplogrednega učinka metana ne pomeni, da so prizadevanja za zmanjšanje izpustov nepotrebna. Metan je zelo potenten toplogredni plin. V kolikor se zaradi povečevanja izpustov koncentracije v atmosferi povečujejo, se podnebje segreva hitreje, kot kaže GWP_{100}. Na drugi strani pa lahko z zmanjšanjem izpustov metana zmanjšamo koncentracije v ozračju in s tem planet ohladimo. Evropa je ta potencial v precejšnjem obsegu že izkoristila, saj je edini kontinent, na katerem se izpusti metana iz živinoreje zmanjšujejo že nekaj desetletij [15]. Za Nemčijo imamo tudi ocene za čas izpred več kot 100 let. Izpusti metana iz prebavil rejnih živali so že od leta 2003 pod ravnjo iz leta 1892 [16]. To pomeni, da je bil prispevek nemške živinoreje h koncentracijam metana v ozračju pred 130 leti večji kot sedaj. Potencial za nadaljnje zmanjševanje emisij iz evropske živinoreje obstaja, je pa njegov pomen za podnebne spremembe razmeroma majhen. Na globalni ravni prispevajo naravni viri 50,5 % vsega metana, fosilna goriva 17,4 %, živinoreja 15,1 %, deponije in odpadki 8,9 %, gojenje riža 4,1 %, sežiganje biomase 2,3 % in raba biogoriv 1,6 % [15]. Prispevek evropske živinoreje k skupnim globalnim izpustom je 1,5 % [15] in za toliko bi se zmanjšala koncentracija metana v ozračju, če bi ukinili vso evropsko živinorejo.

Uporaba metode GWP* je deležna precej pozornosti tako v znanstveni in strokovni literaturi, kot tudi v javnih medijih. Ob izpostavljanju njenih prednosti je deležna tudi kritik glede pravičnosti in poštenosti [17] in zlorab v smislu prikazovanja podnebne nevtralnosti živinoreje [18]. Do držav, ki so v preteklosti izkazovale velike izpuste in so te izpuste v zadnjih 20 letih zmanjšale, je metodika GWP* kljub velikim izpustom metana na prebivalca zelo prizanesljiva [17]. To sicer velja tudi za GWP_{100} saj so praktično vse mednarodne zaveze na področju blaženja podnebnih sprememb določene v % glede na izhodiščno leto. Res pa je, da pride zaradi kratke obstojnosti in s tem specifičnega izračuna GWP*, vsako zmanjšanje izpustov metana bolj do izraza, kot kažejo absolutne vrednosti izpustov. Pri morebitnem omenjanju podnebne nevtralnosti živinoreje moramo biti precizni in navesti, ali se le ta nanaša le na metan, ali pa tudi na didušikov oksid (kot na grafu 1) ali pa tudi na druge z živinorejo povezane toplogredne pline, ki jih UNFCCC ne poročamo v sklopu sektorja živinoreja.

Sklenemo lahko, da splošno uveljavljena metoda obračunavanja ekvivalentov CO_2 močno precenjuje učinek slovenske živinoreje na segrevanje podnebja. Z nadaljnjim zmanjševanjem izpustov metana v živinoreji lahko sicer prispevamo k ohlajanju podnebja, pri tem pa je potencial evropske živinoreje zaradi zmanjšanja emisij v preteklosti in zaradi obsežnih drugih virov razmeroma majhen.

4 ZAHVALA

Prispevek je bil pripravljen v sklopu projekta V5-2366 »Ovrednotenje dejavnikov za učinkovito zniževanje emisij toplogrednih plinov«, ki ga sofinancirata Agencija za raziskovalno dejavnost Republike Slovenije (ARIS) in Ministrstvo za okolje, podnebje in energijo Republike Slovenije (MOPE) in v sklopu raziskovalnega programa »Trajnostno kmetijstvo« (P4-0133), ki ga sofinancira Agencija za raziskovalno dejavnost Republike Slovenije (ARIS) iz državnega proračuna.

Oblikovanje specifičnih habitatov kot ukrepanje za zmanjšanje vplivov hidroelektrarn na okolje

Design of specific habitats as a measure to reduce the impacts of hydropower plants on the environment

Andraž Hribar
Služba za gradbeništvo in okolje
HESS, d. o. o., Brežice, Slovenija
andraz.hribar@he-ss.si

Povzetek

Zajezba na vodotoku je tisti del vsake hidroelektrarne, ki predstavlja največjo spremembo v prostoru in ima velik vpliv na okolje v času obratovanja HE. Sodobni pristopi k umeščanju akumulacij zahtevajo celovit in multidisciplinaren pristop ter vključitev različnih deležnikov. Vključevanje širokega kroga strokovnjakov iz različnih področij po eni strani odpre veliko vprašanj, po drugi strani pa omogoči takšno ukrepanje, ki zmanjša vpliv ob umestitvi objekta in tudi v času obratovanja. Primer iz prakse so pretočne akumulacije na spodnji Savi, kjer so se v času gradnje uredili nadomestni habitati, v času obratovanja pa se na podlagi monitoringov in sodelovanja s strokovnjaki s področja ekologije, biologije in drugih naravoslovnih ved zbirajo podatki in oblikujejo nova znanja o prostoru. To omogoča prilagajanje spremembam v naravi, ki so neizbežne: ravno narava je tista, ki daje prostoru dinamiko. Statični objekti, kakršne naj bi bile hidroelektrarne, se morajo prilagajati tej dinamiki z novimi ukrepi, ki ne nasprotujejo naravi temveč sprejemajo nove naravne danosti in gradijo na prednostih, ki jih pretočne akumulacije nudijo. Vzdrževanje hidroelektrarn naj bi bila načeloma rutinska aktivnost. Vendar nova spoznanja v migracijah organizmov (na primer ribe), prihod novih vrst v prostor (na primer bober), širjenje novih tujerodnih vrst (trikotna ladjica), spremembe v hidrološkem režimu reke (prehod Save iz snežno-dežnega režima v dežni režim) in klimatske spremembe zahtevajo razvoj in prilagajanje. Vsi novi ukrepi se dandanes morajo izpeljati po načelih krožnega gospodarstva, upoštevati pa je potrebno tudi spremljanje ogljičnega odtisa, kar je pri aktivnostih vezanih na sedimente vse pomembnejše vprašanje. V družbi HESS imamo postavljen dvojni sistem: spremljanje stanja pretočnih akumulacij v našem upravljanju na eni strani in oblikovanje nabora zaželenih ukrepov za povečanje okoljske in družbene vrednosti. Sistem omogoča primerjavo obeh sklopov in ukrepanje na način, da se ob vsaki sanaciji ali modifikaciji doseže dodana vrednost. Primerov tovrstnega ukrepanja na spodnji Savi je veliko, trenutno v fazi realizacije je projekt ureditve brežine Kompolje an pretočni akumulaciji HE Boštanj.

Ključne besede

Zmanjšanje vplivov energetskih objektov, večanje okoljske vrednosti, vzdrževanje z dodano vrednostjo, ekološka gradnja, sonaraven razvoj

Abstract

Basin of each Hydropower plant represents the biggest spatial change and has the biggest impact on the environment during the operation of the HPP. Modern approaches to the implementation of the basin require a comprehensive and multidisciplinary approach and the involvement of various stakeholders. The involvement of a wide range of experts from different fields opens up many questions. On the other hand it enables such action that minimizes the impact while building the HPP and also during operation. On the lower Sava several examples of good practice can be seen. During construction substitute habitats were arranged and during operation data is collected and new knowledge about ecosystem is developed based on monitoring and cooperation with experts in the field of ecology, biology and other natural sciences. This is the basis of adaptation to the changes in nature, which are imminent. Facilities, such as HPP are designed to be static but that is not how nature works. We must adapt to dynamic dictated by nature with new measures that do not oppose but accept new natural conditions and build on the advantages that HPP basins offer. Maintenance of hydroelectric power plants is supposed to be a routine activity in principle. However, new findings in the migration of organisms (for example different fish species), the arrival of new species in the area (for example beaver), the spread of new non-native species (triangle boat), changes in the hydrological regime of the river (the transition of the Sava from a snow-rain regime to a rain regime) and climate change requires development and adaptation. All new measures nowadays must be carried out according to the principles of the circular economy, also the carbon footprint must be taken into account, which is an increasingly important issue for activities related to sediments. At HESS, we have a dual system when designing modifications of the HPP basins: on the one hand, monitoring of the basins. On the other hand creating a set of desirable measures to increase environmental and social value. This enables the comparison of the two data sets and achieving added value with each renovation or modification.

There are many examples of good practices on the lower Sava river developed by this principle. Currently the project to improve the bank of Kompolje at the Boštanj HPP is in the phase of development.

Keywords

Reducing the impact of energy facilities, increasing the environmental value, maintenance with added value, eco-development, sustainable development

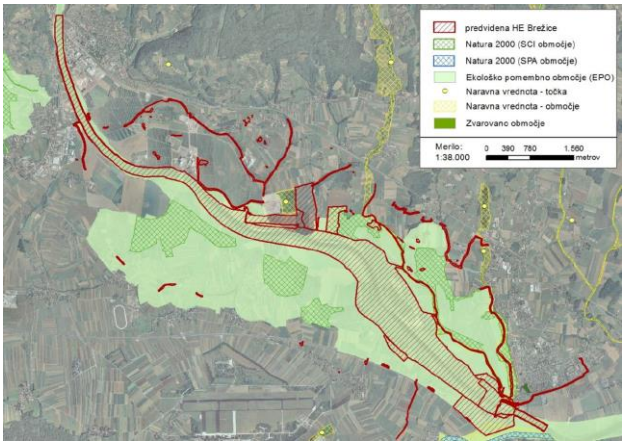
1 Uvod

Razmišljanje o varovanju narave ob umeščanju novega objekta ali nove ureditve v prostor je dejansko primerjava med tistim, kar je, in tistim, kar bo. Zatakne se že pri prvem delu: tistim, kar je, oziroma povedano drugače, stanje, v katerem je narava v tem trenutku. Ali je stanje v tem trenutku res tisto, kar želimo ohranjati? Če govorimo o rekah, varstveniki v Srednji Evropi pogosto štejejo, da je bilo »optimalno naravno« stanje rek v obdobju med 1800 in 1850, ko je bila »dosežena« največja vrstna pestrost v biološkem smislu [1], [2]. Če upoštevamo podatek, da je po ocenah v Srednji Evropi tako ali drugače degradiranih 95% vodotokov, se dandanes torej neizogibno že v štartu vedno pogovarjamo zgolj o tem, kako zelo je stanje degradirano. Ali pri spreminjanju (umeščanju novega objekta oz. ureditve) torej resnično želimo ohraniti to, kar je, se pravi degradirano stanje? Vsaj nekateri bodo rekli, da ne. Želimo si več, nekaj boljšega. Tudi ostali, bolj previdni, se bodo verjetno strinjali, da je nekaj boljšega vsekakor zaželeno.

Drugi del uvodnega stavka »kar bo« se nanaša na načrtovanje in predvidevanje, v kakšnem stanju bo narava po izgradnji oz. po ureditvi. Sodobni pristop je vključevanje širokega nabora strok in znanj, s ciljem nedvoumno zapisati kaj in kako mora biti. Nesporno danes vemo veliko. Znanstveni pristop je temelj današnjega razvoja, zato naj bi mu sledili vsi naravoslovni strokovnjaki (tako inženirji kot biologi). Vendar znanstveni pristop od nas zahteva tudi pogled na celotno sliko (ne spreglejmo gozda pri proučevanju listov). Zanimiv primer je širjenje pristanišča v Singapurju. Habitati in z njimi celoten ekosistem so seveda popolnoma drugačni kot v Sloveniji, posegi in posledice kot proces ter kvaliteta in strokovnost napovedi pa so poučne. Singapur s pristaniščem je eno najhitreje razvijajočih se območij na svetu in je v direktni koliziji s koralnim grebenom, ki je nekoč pokrival več kot 100 km2. Niti nasprotniki uničevanja koralnega grebena niti strokovnjaki na investitorjevi strani pa niso pričakovali, da se bodo korale in z njimi celotni koralni ekosistem pojavil na podvodnih pilotih pomolov [3]. Ko so ugotovili razcvet narave na podvodne stebre, je bilo retrospektivno logično, da se bo to zgodilo: gre za ogromno novih površin, točno na globini z dobro osvetljenostjo in pod vplivom neurij, ter za zaščiteno območje, na katero plovba ne vpliva (pod pomoli). Nekaj, kar je iz retrospektivnega vidika samoumevno, ni znal (pred tem) nihče napovedati.
Znanstveno se je vprašati: Česa vse še ne vemo?

2 Primeri »naravnih« habitatov

Preselimo se bližje nam, v Slovenijo, na spodnjo Savo. V trenutku umeščanja HE Brežice v prostor so strokovnjaki ustvarjali rešitve (prostorske ureditve), ki bi v naravi ustvarile določene pogoje in prostor za življenje določenih organizmov. Pri tem so se strokovnjaki v veliki meri naslanjali na elemente, ki jih je ustvarila narava in so (bili) domovanje številnih organizmov: Poplavni gozd imenovan Vrbina pri Brežicah, gramozne jame, suhi travniki, mlake in jezera. Pa jih je res ustvarila narava?

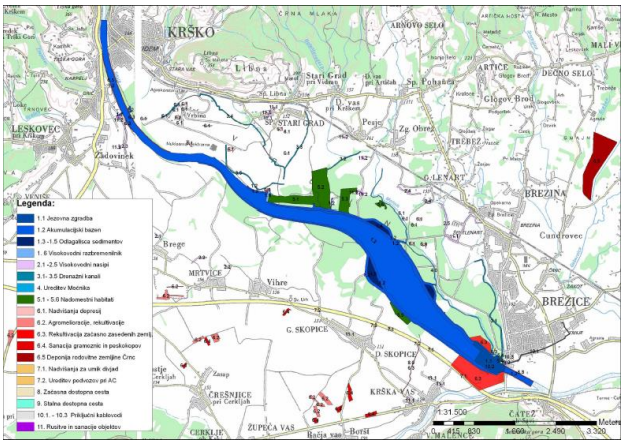


Slika 1: Varovana območja in prikaz infrastrukturnih ureditev HE Brežice [5]

V poplavnem gozdu Vrbina pri Brežicah rastejo v večini topoli, ki so jih zasejali od leta 1952 naprej za potrebe proizvodnje papirja v Tovarni papirja Krško. Gre za v vrste zasajene topole, celoten nasad, na začetku velik 17 ha, v letih največjega obsega pa je pokrival 555 ha. Razdeljen je bil v kvadrante in ločen s pravokotnimi gozdnimi cestami. Posamezne kvadrante so izsekavali z golosekom, ko je bila lesna masa zrela, in zasajevali s sadikami, ki so jih gojili v bližnji drevesnici. Da so ustvarili prostor za nasad topolov, so izkrčili dotedanji poplavni gozd, ki ga je pred tem sestavljal dob (vrsta hrasta). Dob je veličastno drevo, visoko do 40m in s premerom debla tudi več kot 2m. Topol je hitro rastoče drevo, ki hitro nabira lesno maso in je po 8-10 letih pri debelini debla 20 cm že primerno za posek [4]. Sprememba iz naravnega dobovega poplavnega gozda v topolov nasad je nedvomno pomenila izredno osiromašenje ekosistema. Šlo je za industrijski poseg brez okoljevarstvenega razmisleka. Zadnje zasaditve so se izvajale leta 2009, od takrat naprej pa nasad »propada«. Propada seveda le z vidika industrije in proizvodnje lesne mase, z vidika naravovarstva pa se je takrat pričelo uravnoteženje ekosistema z naravnim procesom naseljevanja drugih organizmov in upadanjem monokulture (topola), ki je z vidika narave nevzdržna. V teh razmerah so se na območju naselili nekateri organizmi, med drugimi tudi hrošč škrlatni kuku, ki je v odmirajočem lubju dreves našel zanj bogat življenjski prostor. Rezime: Pri gradnji HE Brežice smo varovali umetno ustvarjen habitat, za katerega se ob nastanku ni smatralo, da bo imel kakšno naravovarstveno vrednost (nasad monokulture), pri čemer se varuje takšno stanje habitata, ki je iz naravnega vidika nevzdržno (naravno nevzdržna prevlada enega

tipa habitata, ki je na kratek rok povzročil ekspanzijo določenega tipa organizma).

Reka Sava je pred izgradnjo HE Brežice predstavljala cca 90m široko strugo v obliki trapeznega korita z utrjenimi brežinami in poplavnim območjem okoli struge. Poplavno območje je bilo ponekod omejeno z varovalnimi nasipi, kjer ni bilo ogroženih objektov, pa se je prosto razlivala. Gramozne jame oz. gramoznice so jame, iz katerih se izkopava gramoz. Ker segajo pod gladino podtalnice, gre v naravi za jezera. Navadno se gramoznica širi v eno stran, tako da se fronta izkopa premika, preostale brežine pa se sčasoma zarastejo in postanejo domovanje za številne organizme. Umetna jama torej s časoma ustvari različne tipe habitatov; od strmih brežin do položnejših, od golih do zaraščenih, od čiste prodnate obale do korenin in mulja v plitvini. S poplavljanjem reke se v ta vodna telesa naselijo ribe, poplavno premeščanje sedimenta pa premesti tudi organizme iz dna vodotoka, ki predstavljajo hrano ribam in dvoživkam. Dvoživke s selitvijo najdejo nove vodne površine, ptiči in mrčes se naselijo še hitreje. Osredotočimo se na ptice, posebej ogrožene vrste lastovke breguljke in čebelarje. Te ptice vsako leto ob selitvi iz Afrike poiščejo sveže erodirano območje ob reki, kjer je voda ob zadnjih spomladanskih poplavah odnesla breg in ustvarila strmo prodnato brežino. V brežini izkopljejo rov v produ, strma brežina nad vodo pa jih varuje, da do gnezd ne pridejo kače in lisice. Reka Sava je prenehala odnašati brežine zaradi stoletja ukalupljanja v trapezoidno strugo z utrjenimi brežinami. Klimaks ukalupljanja se je odvil med leti 1850 in 1950 z gradnjo južne avstroogrske železnice (odsek Zidani Most – Sisak), z gradnjo cest (ob spodnji Savi je potekala že rimska cesta med Celeio (Celje) in Neviodunum (Drnovo pri Krškem, kjer je bilo pomembno pristanišče), s širitvijo mest in razvojem industrije (Radeče, Sevnica, Krško), ne gre pa zanemariti niti vpliva širjenja obdelovalnih površin. Tudi v času Jugoslavije se je ukalupljanje nadaljevalo, kar je lepo razvidno iz katastra vodnogospodarskih ureditev. Rezultat ukalupljanja pa je fiksirana brežina, ki je voda ne erodira in ne ustvarja novih golih strmih brežin, ki jih potrebujejo breguljke in čebelar. Zato so ptice našle nove lokacije vedno novih primernih brežin – v gramoznicah, točno na fronti odkopa, kjer je vsako leto sveža brežina.



Slika 2: Prostorski prikaz posegov ob gradnji HE Brežice [5]; opis nekaterih oznak, za pojasnilo opisov v članku: 5.1, 5.2 in 5.5 so Nadomestni Habitati (NH) 1, 2 in 5, ki predstavljajo nove vodne površine kot nadomestilo za nekdanje gramoznice. 5.3 je NH3, ki v južnem delu predstavlja nove gozdne površine, v severnem delu pa novi suhi travnik. 5.6 je NH6, kjer se nahaja jezero/mlaka za želvo sklednico.

Rezime: Gramoznica je škrbina v okolju (za vsako gramoznico se mora v sklopu pridobitve koncesije izdelati tudi projekt sanacije). Ob podeljevanju koncesij za izkop se gramoznice obravnavajo kot poseg v okolje brez kakršne koli ekološke vrednosti. V primeru gradnje pretočne akumulacije HE Brežice, s katero se je potopilo nekaj gramoznic, pa se je te "škrbine" moralo nadomestiti, tako da so se zgradile nove, nadomestne prodne stene nad vodno površino, s katerimi se je simuliralo habitate v gramoznicah.

3 Primeri »umetnih« habitatov

Je habitat lahko umeten? Habitat je življenjski prostor, torej nekaj naravnega. Če ga zgradi človek, je lahko to naravno? Bistvo narave so procesi, procesi ustvarjajo spremembe, ravno spremembe pa so tista dinamika, ki ustvarja pestrost habitatov, kot na primer različne globine vode, različne brežine gramoznic, različna kvaliteta prsti, različna granulacija sedimenta. Te razlike omogočajo različnim organizmom lokalne pogoje za življenje, zato je ta dinamika tako pomembna. Ko gradi človek, navadno gradi nekaj fiksnega, nekaj, kar bo stalo čvrsto skozi celotno življenjsko dobo. Vsak objekt mora izpolnjevati bistvene lastnosti. Je to združljivo z naravo?

V prejšnjem poglavju opisano ukalupljanje reke je Savi onemogočilo premikanje struge. Kot že omenjeno, je bila reka Sava pred izgradnjo HE Brežice široka cca 90m. Kartografski arhivi avstro-ogrskih katastrov pa na območju Brežic prikazujejo reko, katere glavna struga je široka 500m, zraven nje pa več stranskih strug, rokavov, meandrov in drugih oblik (okljuki, zalivi, mrtvice, jezera…). Vse te oblike nastajajo, ko reka ob poplavah ustvarja novo glavno strugo, stara struga pa se postopoma zamulji, preide v rokav, nato jezero, nato mrtvico, mlako, močvirje in na koncu v suha (občasno poplavljena) tla. Takšne reke od 19. stoletja pri Brežicah ni več, še vedno pa so ostanki nekdanjih strug in drugih vodnih oblik. Tovrstne mlake in močvirja so (bila) pester habitat in zato se je ob gradnji HE Brežice zgradilo nove tovrstne oblike. V prostor se je torej želelo umestiti nekaj, kar je izgubil že več desetletij nazaj. Ni se zgolj ohranjalo stanje reke pred izgradnjo HE Brežice, temveč se je želelo »izboljšati« trenutno stanje narave. Primer takšnega ukrepa je habitat imenovan NH6, ki je bil prioritetno namenjen želvi sklednici. Habitat se je zasnoval kot napol jezero in napol mlaka, z dinamično brežino in globinami ter dovolj golega, prodnatega prostora ob vodi, kjer si lahko želve ustvarjajo gnezda in se sončijo. Vsi podatki po izgradnji so kazali na uspeh. Po nekaj letih »obratovanja« habitata pa so se zgodile določene spremembe: ker ni tekoče vode, ki bi občasno poplavila prodišče, se slednje zarašča in želve izgubljajo prostor za sončenje. Iz bližnjega potoka je bober skopal kanal do mlake in si v mlaki zgradil gnezdo. Po kanalu dostopa do tekoče vode in preko nje do prostora za hranjenje. Narava gre svojo pot. Potekajo naravni procesi, s katerim pa izgubljamo prvoten namen habitata. Ali je ta objekt uspešno zgrajen? Ali uspešno »obratuje«?

Slika 3: Nadomestni habitat 6 (NH6), namenjen želvi sklednici, cca 2 leti po izgradnji. Vidne so prvotno gole površine proda, ki se postopoma zaraščajo. Na desni je vidno porušeno drevje, kjer je aktiven bober [8].

Suhi travniki so nastajali na območjih, kjer je reka nasipala prod. Takšna neugodna rastišča so najprej naselile pionirske rastline, ki so ustvarile tanek sloj humusa, slednji pa je omogočal razrast nezahtevnih rastlin. Večje rastline je ob poplavi odneslo in s tem je nastal specifičen travniški habitat s pestrim ekosistemom rož, med katerimi je 25 ogroženih vrst [5]. Ob umeščanju HE Brežice v prostor se je rezerviral tudi prostor za tovrstne habitate, imenuje se NH3. Pred pripravila so se tla in simulirali pogoji, kakršni majdemo na naravnih suhih travnikih. Tako kot vsaka naravna oblika, tudi suhi travniki preidejo v naslednji stadij, saj večanje debeline humusa tudi večjim rastlinam omogoči, da ustvarijo dovolj bogat koreninski sistem, ki zdrži poplave. S časoma tako travnik preide v gozd. Če se ta naravni proces odvije na zgrajenem habitatu, kateremu je dodeljen namen, ali je projekt uspešen? Ali habitat obratuje uspešno, ali se bo okrivilo tistega, ki je zadolžen za vzdrževanje, da ni ohranjal ustreznih pogojev (ni ohranjal tal dovolj siromašnih)?

4 Ima naravni habitat fazo obratovanja?

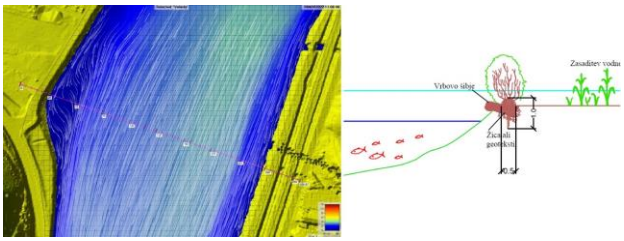
Na spodnji Savi trenutno obratuje 5 HE s pripadajočo vplivno površino. Ukrepi, izvedeni v času gradnje posamezne HE, so predani različnim upravljalcem. To še posebej velja za HE Brežice. Pri gradnji prejšnjih elektrarn se je malo ali delno dajala pozornost naravi, HE Brežice pa je pilotni projekt v Sloveniji, celo v svetu, glede pozornosti, ki se je namenila naravi. V prvi vrsti se je opredelilo vse naravne vrednosti, nato razmišljalo o možnih ukrepih, se ukrepe zasnovalo ali sprojektiralo in na koncu so se objekti in ureditve zgradili, aktivnosti in procesi pa pričeli, pri čemer se je določil tudi izvajalec teh aktivnosti. Na primer, obratovanje prehoda za vodne organizme za premostitev višinske razlike v gladinah vode nad in pod jezovno zgradbo, v katerem se mora ohranjati ustrezna vodnatost/pretočnost ne glede na hidrološko-hidravlične pogoje v reki Savi. Drug primer je že omenjena brežina za breguljke in čebelarje; ker ni vode, ki bi erodirala, niti ni izkopa gramoza, ki bi ustvarjal svež izkop, je potrebno ohranjati strmo brežino na način, da se odkoplje tisti material, ki ga padavine erodirajo. Tam, kjer je predpisano navodilo za vzdrževanje, torej lahko govorimo o obratovanju, tudi če gre za naravovarstveno ureditev. Ribe namreč plavajo skozi prehod za vodne organizme, celo veliko jih je, in ptice tudi kopljejo vsako leto nova gnezda v umetno zgrajenih brežinah. Kjer je naravna oblika ustvarjena, pa je ocenjevanje uspešnosti nesmiselno. Narava je namreč vedno uspešna, vprašanje je samo, ali je ljudem njena rešitev všeč. Obratovanje torej ne obstaja, saj je obratovanje po definiciji ponavljajoč proces. Gonilo narave pa je sprememba.

5 Pristop k izgradnji novega naravnega habitata

Sedaj znamo pristopati znanstveno in multidsciplinarno, zavedamo se, kako »deluje« narava, razumemo spremembe v naravi, poznamo pomen naravnih oblik in opremljeni smo z znanjem (tako tehničnim kot biološkim), kako oblikovati prostor na način, da bo primeren za izbrane organizme.

Slika 4: Otok nanosa (sedimenta) na pretočni akumulaciji HE Boštanj na reki Savi [6].

Na pretočni akumulaciji HE Boštanj se v bližini naselja Kompolje nahaja zožitev struge. Pred zožitvijo ob desnem bregu voda zaradi hidravličnih razmer zastaja in odlaga nanos (imenovan tudi sediment). Ker voda v pretočni akumulaciji dnevno niha zaradi proizvodnje električne energije in ker je odloženega že toliko nanosa, je tam pogosto viden otok. Ker je nanos, ki ga nosi reka Sava, v glavnem zelo drobnozrnat in z veliko organskimi primesmi, otok izgleda kot kup mulja. Fizikalne lastnosti tega materiala so takšne, da zadržuje vodo. Ker je lahek, se ne posede, ne konsolidira in zaradi tega tudi ne more ustvariti dovolj čvrste podlage, na kateri bi se lahko naselile rastline, čeprav je semen v vodi vse polno, kakor pričajo različna testiranja, ki smo jih opravili. Ideja je torej, da ne obnovimo brežine v osnovno obliko trapeznega korita, utrjenega s skalometom, temveč da uporabimo lokalne hidravlične razmere in omogočimo naravi njen razvoj. Po pogovorih z ZRSVN smo prišli do zaključka, da bi bilo na območju HE Boštanj koristno ustvariti boljše pogoje za vidro. Zato je ideja, da to lokacijo, ki trenutno nima bistvene ekološke vrednosti, preuredimo na način, da bo vsaj sprva tu našla svoj življenjski prostor vidra, kasnejši naravni razvoj pa bo pokazal, kakšne načrte ima narava.



Slika 5: Rezultati študije ureditve brežine [7]. Levo: Prikaz rezultatov hidravličnih izračunov. Desno: Prikaz idejne rešitve ureditve brežine.

Hidravlična analiza je pokazala, da ni ovire za ureditev brežine, ki bo ustvarila kombinacijo čvrste površine in vodnih lagun, saj tudi ob najvišjih pretokih reka Sava na tem mestu ne bi odnašala materiala. Izdelali smo idejno zasnovo brežine in sedaj pristopamo k izdelavi projekta za izvedbo nove brežine. Ustvarili bomo lepšo brežino, ki ne bo kazila podobo reke Save, na in ob kateri poteka rekreacija in turizem. Vpliv na proizvodnjo je zanemarljivo majhen, saj že sedaj otok zmanjšuje prostornino vode, ki se uporablja za proizvodnjo električne energije. Stroški vzdrževanja bodo manjši, saj ne bo potrebno čiščenje in ohranjanje osnovne utrjene brežine. Narava pa bo dobila nov prostor.

6 Prihodnost sodelovanja z naravo

Je z naravo možno sodelovati? Je narava pripravljena sodelovati? Vse, kar lahko naredimo, je, da se zavedamo naravnih procesov, jih poskušamo čim bolj razumeti in spoznati njihovo kompleksnost ter povezanost. Elektro energetski objekti se ne umeščajo, ker bi bili sami sebi namen, umeščajo se z razlogom. Ker jih potrebujemo. Hkrati je smiselna določena doza samokritičnosti pri »predpisovanju« naravnih procesov in pri napovedovanju, kaj bo narava naredila ali kaj glede okolja lahko pričakujemo v prihodnosti. Dejstvo je, da ne vemo vsega, kompleksnost narave pa je osupljiva, zato je smiselna določena doza ponižnosti. Človek potrebuje svoj prostor za življenje, ravno tako ga narava. Razmišljanje o naravi je še kako ključno, če želimo ljudje preživeti na tem planetu. Izgradnja HE Brežice je primer dobre prakse glede pozornosti, ki se je je namenilo naravi, glede truda in znanja, ki se ga je vložilo, in tudi glede na novo pridobljenega znanja. Predvsem pa je dobra praksa v tem, da se je ob gradnji HE zagotovil in uredil prostor tudi za naravo. S tem se omogoča naravna dinamika in dogajanje sprememb v okolju, kajti to je naravno. Tudi če kakšen ukrep sedaj ni popolnoma takšen, kot se je sprva zastavil, gre še vedno lahko za primer dobre prakse. V najslabšem primeru kot pokazatelj, kaj lahko naredimo še boljše.

7 Zaključki

Ker je celoten članek napisan v poljudnem stilu, naj zaključim s tehničnim komentarjem. Tehniki smo navajeni ravnati s številkami, vrednotiti po kriterijih in razvrščati v razrede. Naravo je težko razvrščati na tovrsten matematičen način iz več razlogov. V prvi vrsti so naravni sistemi preveč kompleksni, da bi jih enoznačno vrednotili, pogosto pa jih niti ne razumemo v celoti. Pomen naravnih oblik in njihovo vrednost vedno vrednotimo z antropološkega vidika, ki je avtomatsko subjektiven. Objektivna ocena vrednosti ni možna, še manj z vidika narave. Vrednosti posameznega organizma ali lokalnega habitata za celoten ekosistem ni mogoče ovrednotiti.

Slika 6: Primer tipičnega vodnega telesa s habitatno diverziteto, kakršna se je umeščala na potokih v bližini HE Brežice [8]. Proces erodiranja na levi strani slike ustvarja strmo brežino, v kakršni lastovice breguljke in čebelarji gradijo gnezda. Na desni strani poteka odlaganje in ustvarjanje prodišča, kjer pričenjajo z rastjo pionirske rastline, na kamnih pa se sončijo želve. Plitvine in tolmuni ustvarjajo različne pogoje za različne velikosti rib, različno obvodno rastlinje pa hrano za različne organizme. "Izgradnja" tovrstne ureditve neizbežno vodi v spremembo, saj bo narava že ob prvem dežju takšen "objekt" spremenila. Faza obratovanja takšnega "objekta" v smislu ponavljanja procesov zato ne obstaja. Vse, kar lahko ljudje naredimo, je, da zagotovimo prostor in pustimo naravnim procesom naravno pot.

Za konec upoštevajmo še človeški faktor in različne razloge za ravnanje posameznikov, tudi inženirjev in znanstvenikov, ki pogosto upoštevajo zgolj tisto, kar se je dogodilo v njihovi karieri, preteklost in prihodnost pa presegata okvir njihovega zanimanja. Narava ni tako ozkogleda, zato si je treba priznati, da vsega pač ne vemo. Ukrepe, za katere so bili strokovnjaki čvrsto prepričani, da bodo delovali, je narava »odpeljala po svoje«. Degradiranost okolja je narava pogosto preoblikovala v nekaj nepričakovanega, kar čez desetletja cenimo in želimo ohraniti. Zato posegi v prostor, kakršne so tudi gradnje elektro energetskih objektov, niso nujno takšna degradacija okolja, kakršna izgleda na prvi pogled. Zaradi našega lastnega obstoja na planetu je brez dvoma potrebno pri umeščanju v prostor vložiti trud, čas in denar tudi v ohranjanje narave. Pri tem ni smiselno, da ohranjanje narave temelji strogo na načrtovanju in predvidevanju naravnih procesov in naravnega stanja, temveč je preudarno vsaj deloma dovoliti, da naravni procesi oblikujejo prostor tudi po lastni poti. Sodobni pristopi k umeščanju zahtevajo tovrstno širokoglednost, potrebna pa je tudi multidisciplinarnost, da se naslovi vse ekološke vidike. Tudi v 3. fazi projektov, fazi obratovanja, je pri vsaki spremembi prostor, da se razmisli o možnosti sonaravnega ukrepanja, pri čemer je sonaravno ukrepanje že to, da se da naravi prostor.

Axioms and Myths of Environmental Care and Sustainable Agriculture

Aksiomi in miti o varovanju okolja in trajnostnem kmetijstvu

ABSTRACT.
This paper challenges common misconceptions about agriculture's impact on the environment, particularly the idea that agriculture is inherently harmful. By providing insights into natural cycles, methane dynamics, and biodiversity benefits, the study highlights how well-managed agricultural practices, such as diverse crop management and rotational grazing, contribute positively to the environment. Contrary to the myth, correctly managed farmland and pastures foster biodiversity, support soil health, and integrate animals as a natural part of ecosystems. The paper compares the environmental impact of agriculture with other sectors and emphasizes the need for a nuanced understanding of sustainability in agriculture.

POVZETEK
Prispevek izpodbija običajne napačne predstave o vplivu kmetijstva na okolje, zlasti idejo, da je kmetijstvo škodljivo okolju. Z analizo naravnih ciklov, dinamike metana in koristi biotske raznovrstnosti, študija poudarja, kako dobro upravljane kmetijske prakse, kot so raznovrstne poljščine in rotacijska paša, pozitivno prispevajo k okolju. Nasprotno mitu, pravilno obdelana kmetijska zemljišča in travniki spodbujajo biotsko raznovrstnost, podpirajo zdravje tal in vključujejo živali kot naravni del ekosistemov. Prispevek primerja okoljski vpliv kmetijstva z drugimi sektorji in poudarja potrebo po bolj natančnem razumevanju trajnostnosti v kmetijstvu.

KLJUČNE BESEDE
Trajnostno kmetijstvo, metan, biotska raznovrstnost, ekosistemi, upravljanje kmetijskih zemljišč

KEYWORDS
Sustainable agriculture, methane, biodiversity, ecosystems, farmland management

1 Uvod

Kmetijstvo, kljub svoji nujni vlogi pri zagotavljanju hrane za svetovno prebivalstvo, pogosto napadajo, češ da onesnažuje okolje. To prepričanje izhaja predvsem iz dveh dejavnikov: izpustov toplogrednih plinov, zlasti metana, ki ga proizvajajo prežvekovalci, in degradacije tal zaradi intenzivnih kmetijskih praks. Vendar pa so te predstave pogosto poenostavljene in ne upoštevajo ključnih dejstev, kot so naravni cikli metana, trajnostno upravljanje kmetijskih zemljišč in pomen biotske raznovrstnosti, ki jo lahko podpirajo dobro upravljane kmetijske površine [1][2].

Dobro upravljano kmetijstvo, zlasti ekstenzivne metode, kot sta rotacijska paša in ohranjevalno obdelovanje tal, ima zelo pozitivne vplive na okolje. Na primer, travniki in pašniki lahko gostijo večjo biotsko raznovrstnost kot mnogi gozdni ekosistemi, saj omogočajo habitat za številne rastlinske in živalske vrste [3]. Poleg tega so tla na trajnostno upravljanih kmetijskih površinah sposobna skladiščiti več ogljika, kar pripomore k zmanjševanju koncentracij toplogrednih plinov v ozračju [4]. Primerjave z zagrajenimi površinami (ceste, parkirišča, stavbe) so seveda nesmiselne, saj je v resnici kmetijske površine najbolj biološko "bogate", človeško degradirane pa najmanj.

Čeprav zlasti živinoreja prispeva k proizvodnji metana, enemu glavnih toplogrednih plinov, pa se metan v ozračju ohranja le približno 12 let, kar pomeni, da so njegovi dolgoročni učinki bistveno manjši kot pri CO2 [5]. Poleg tega nove tehnologije in prakse, kot so dodatki za prehrano živali, lahko bistveno zmanjšajo emisije metana iz živinoreje [6].

Kmetijstvo je tudi ključno za ohranjanje biotske raznovrstnosti. Dobro upravljana kmetijska zemljišča zagotavljajo pomemben prostor za številne vrste, ki jih ne najdemo v intenzivno gozdnih ali urbaniziranih območjih. Raznolikost vrst na takšnih površinah prispeva k stabilnosti ekosistemov in omogoča večjo odpornost na podnebne spremembe in druge stresne dejavnike [7].

Cilj tega prispevka je podrobneje raziskati vpliv kmetijstva na okolje, zlasti v povezavi z izpusti toplogrednih plinov, biotsko raznovrstnostjo in trajnostnim upravljanjem naravnih virov, ter izpodbijati nekatere uveljavljene mite o kmetijstvu kot največjem onesnaževalcu. Poleg tega bomo preučili, kako lahko trajnostno kmetijstvo prispeva k zmanjševanju negativnih

vplivov na okolje in pomaga pri reševanju nekaterih ključnih okoljskih izzivov.

Da bi argumentirali vlogo in pomen kmetijstva v smislu varovanja okolja, najprej naredimo širšo analizo varovanja okolja, ki temelji na [8, 9, 10]. Naredimo tako analizo aksiomov, osnovnih usmeritev varovanja okolja v sekciji 2, kot tudi mitov v sekciji 3. Zaključimo z diskusijo v sekciji 4.

2 Aksiomi o varovanju okolje

Aksiomi (osnovne usmeritve) varovanja okolja so:

2.1. Rast števila ljudi in standarda je osnovni pritisk na okolje

Ljudje za svoje delovanje in udobje uporabljajo energijo, kar pomeni, da več kot je ljudi in višji kot je življenjski standard, več energije je potrebno za zadovoljevanje njihovih potreb. Posledično se povečuje tudi poraba naravnih virov in nastaja večja količina onesnaževanja, ki vpliva na kvarjenje okolja.

Čeprav se rast svetovne populacije postopoma upočasnjuje, zlasti zaradi nizke rodnosti na večini celin (razen v Afriki, kjer rodnost ostaja visoka), to pomeni, da je v prihodnosti čedalje pomembnejši dejavnik vpliv posameznika na okolje [11]. Ob manjšem številu otrok in staranju prebivalstva bo poudarek na tem, koliko okoljske škode povzročajo posamezni ljudje s svojim načinom življenja in porabo energije. Bolj kot število ljudi bo pomembna njihova potrošnja in ravnanje z naravnimi viri – Koliko površin bodo uničili, koliko onesnaževanja bodo povzročali, Koliko bodo podpirali biotsko raznolikost in sožitje z naravo [12].

Ključen dejavnik v tej enačbi je poselitev – kako in kje so ljudje naseljeni ter koliko prostora je namenjenega različnim dejavnostim, kot so kmetijstvo, industrija, neokrnjena narava in urbani parki. Teoretično bi se vseh 8 milijard ljudi na svetu lahko naselilo na območje velikosti Slovenije, saj bi ob 20.000 km² površine vsak posameznik zasedel približno 2,5 m² prostora.

Torej ta hip število prebivalcev na planetu ni preveliko, če bi delovali smotrno in trajnostno, če bi poseljevali predvsem v mestih, zmanjšali nepotrebno porabo virov in namenjali zadostne površine naravi ter ekosistemom, kjer pomembno vlogo igrajo kmetijske površine in gozdovi.

Trajnostni razvoj bi tako moral vključevati učinkovito rabo prostora, zlasti z vidika urbanizacije in varovanja naravnih območij, ob hkratnem zmanjšanju porabe energije na prebivalca in spodbujanju manj potrošniškega življenjskega sloga. Če bi človeštvo delovalo trajnostno – manj trošilo, učinkoviteje uporabljalo naravne vire in vzdrževalo ravnovesje med človekovo dejavnostjo in ohranjanjem narave – bi trenutna populacija lahko bivala v harmoniji z okoljem brez bistvenih negativnih vplivov na planet [12, 13].

Za Slovenijo in druge države je napotek jasen: treba je stremeti k trajnostni rodnosti (1.9 do 2.2), treba je zmanjšati pritok migrantov – saj to povečuje število prebivalcev in pritisk na okolje. Treba je večino ljudi poseliti po mestih in čim večji del površin nameniti kmetijstvu, gozdarstvu in zavarovanim območjem [8, 11].

2.2. Izgorevanje (fosilnih goriv) največ prispeva k onesnaževanju oz. uničevanju okolja

Vse tehnologije, ki temeljijo na izgorevanju fosilnih goriv (premog, nafta, plin), kot so tiste v prometu, ogrevanju in industriji, prispevajo k izpustom toplogrednih in ljudem škodljivih plinov, kar je glavni vzrok za onesnaževanje okolja. Fosilna goriva so omejeni viri, nastali skozi milijone let iz ostankov starodavnih organizmov, in čeprav predstavljajo izredno zgoščeno energijo, je njihova raba dolgoročno nevzdržna. Po ocenah geoloških raziskav je v zemeljski skorji približno 1.7 trilijona sodčkov nafte, vendar pri trenutni stopnji porabe lahko pričakujemo, da bodo te zaloge izčrpane v nekaj desetletjih. Poleg tega se približno 50 % zalog premoga ocenjuje na količino, ki zadošča še za dobrih 100 let, vendar so tudi te številke odvisne od stopnje porabe [14, 15].

Toplogredni plini, ki nastajajo pri izgorevanju fosilnih goriv, kot so ogljikov dioksid (CO2), metan (CH4) in dušikovi oksidi (NOx), pomembno vplivajo na segrevanje ozračja. Med njimi ima metan sicer večji takojšnji učinek na podnebje, vendar razpade v ozračju v približno 12 letih. Ogljikov dioksid pa ostaja v atmosferi več stoletij, zaradi česar se njegov vpliv dolgoročno kopiči. Prav CO2 je tisti, ki najbolj prispeva k dolgoročnemu segrevanju ozračja in podnebnim spremembam, ker je trajno prisoten v visokem ozračju in povzroča t.i. učinek tople grede.

Zato so tehnologije, ki ne uporabljajo fosilnih goriv, kot so vetrnice, jedrska energija, sončne elektrarne in hidroelektrarne, ekološko bistveno bolj trajnostne. Te tehnologije izkoriščajo naravne vire, kot so veter, voda, sonce ali jedrsko fisijo, ki so v veliki meri obnovljivi in povzročajo manj onesnaženja [16]. Na primer, sončne elektrarne nimajo neposrednih izpustov toplogrednih plinov med obratovanjem, medtem ko vetrnice proizvajajo energijo z uporabo vetrne sile, kar zmanjšuje potrebo po fosilnih gorivih.

Vendar imajo tudi te tehnologije svoje izzive. Jedrska energija, čeprav z nizkimi izpusti CO2, prinaša tveganje v obliki radioaktivnih odpadkov. Vetrne elektrarne lahko vplivajo na lokalne ekosisteme in predstavljajo izziv glede stabilnosti oskrbe z energijo, kadar ni dovolj vetra. Sončne elektrarne pa zahtevajo velike površine zemljišč, kar je hudo problematično (okoljski kriminal v imenu varovanja okolja), zlasti če se postavljajo na kmetijskih območjih ali naravnih habitatih.

Znotraj kmetijstva pa so v zadnjem desetletju v ospredje prišle tako imenovane biogorivne kulture, kot je oljna repica, ki naj bi predstavljale obnovljiv vir energije in zmanjšale odvisnost od fosilnih goriv. Vendar se je pokazalo, da ima proizvodnja biogoriv več negativnih kot pozitivnih učinkov na okolje. Proces pridelave oljne repice za gorivo pogosto zahteva več fosilnih goriv (za gnojenje, obdelavo tal, žetev in predelavo), kot jih biogorivo prihrani ob končni uporabi. To pomeni, da celotni življenjski cikel proizvodnje teh goriv v mnogih primerih ne vodi k zmanjšanju emisij, ampak celo k povečanemu ogljičnemu odtisu [15]. Čemu smo sploh uvedli tovrstne ukrepe, ko pa očitno škodijo okolju?

Za Slovenijo je osnovna trajnostna usmeritev, da opušča predvsem termoelektrarne na premog in se usmeri v jedrsko in trajne vire, kjer je to sprejemljivo in okolju primerno. Vsak ukrep pa mora biti premišljen (primer okoljskega kriminala je postavljanje sončnih panelov na kmetijskih površinah).

2.3. Aksiom: Ohranjanje biotske raznovrstnosti je ključnega pomena za stabilnost ekosistemov

Zmanjševanje biotske raznovrstnosti, ki ga pospešujejo izgorevanje, uničevanje kmetijskih in gozdnih površin, velike kmetijske monokulture in invazivne vrste, zmanjšuje odpornost ekosistemov. Eni izmed dejavnikov zmanjševanja biotske raznovrstnosti so monokulturni sistemi, saj ustvarjajo homogene omejene ekosisteme, kjer je manj prostora za prosto živeče rastline in živali. Prav tako so te kulture bolj občutljive na bolezni in škodljivce, kar zahteva večje količine pesticidov in umetnih gnojil, ki dodatno škodujejo okolju [17, 18, 19]. Za Slovenijo to skoraj ne pride v poštev, saj je večina posestev razparceliranih, medtem ko so v nekaterih državah cele doline namenjeni monokulturi. V tropskih krajih izstopa oljna palma (Elaeis guineensis), iz katere pridobivajo palmovo olje, ki se uporablja v številnih prehrambnih, kozmetičnih in industrijskih izdelkih. Ta kultura vodi v obsežno krčenje gozdov, izgubo biotske raznovrstnosti, emisije toplogrednih plinov ter izpodrivanje lokalnih skupnosti.

Prav tako so invazivne vrste, ki jih pogosto nenamerno prenašamo med različnimi ekosistemi, eden največjih razlogov za izumiranje avtohtonih vrst. Invazivne vrste pogosto izpodrinejo avtohtone zaradi svoje agresivnosti, hitrega razmnoževanja ali pomanjkanja naravnih plenilcev. Poleg tega so nekatere invazivne rastlinske vrste, kot je ambrozija, tudi zelo škodljive za zdravje ljudi, saj povzročajo alergije, in čeprav je potrebno minimalno vsaj avgusta kositi dvakrat, se v Sloveniji v marsikateri občini ne izvaja niti to.

Tudi na videz naravna okolja, kot so strnjeni gozdovi, lahko predstavljajo omejeno biotsko področje, če v njih ni zadostne raznolikosti habitatov. Zato je veliko bolj smiselno ohranjati mozaično krajino, kjer so naravne jase, kmetijske površine med gozdom ali občasne poseke (daleč bolje kot strnjeni gozdovi), ki ustvarjajo raznolikost življenjskih prostorov. Takšna krajina omogoča večji razpon ekosistemov, ki so bolj odporni na spremembe in naravne katastrofe. Gozdovi z jasami ponujajo več možnosti za različne vrste rastlin in živali, kar povečuje stabilnost ekosistema.

Podobno so škodljive genetsko spremenjene rastline, ki so pogosto zasnovane tako, da vsebujejo "naravne" strupe za žuželke, kar ne ustvarja le monokultur, ampak tudi "zastrupljene" monokulture. Te rastline ne škodujejo samo škodljivcem, ampak vplivajo tudi na druge, koristne žuželke in lahko dolgoročno škodijo celotnemu ekosistemu, saj strupi prehajajo skozi prehranjevalno verigo.

Še slabše pa so (avto)ceste, ki predstavljajo povsem mrtva območja za večino živih bitij. Ta območja niso zgolj fizično ovira za prostoživeče vrste, temveč so tudi območja, kjer se pogosto dogajajo trki z živalmi (test avtomobilskega stekla). Poleg tega ustvarjajo prekinitev habitatov, kar vodi do izgube genetske raznolikosti med populacijami in posledično večje občutljivosti na bolezni in okoljske spremembe. Avtoceste so v marsičem »polja smrti«, kjer preživetje vrst ni mogoče, razen tistih, ki se v kovinskih škatlah vozijo naokoli.

Eno izmed pomembnih rešitev za ohranjanje biotske raznovrstnosti je tudi sistematično odstranjevanje invazivnih vrst z ustrezno zakonodajno podporo. Na primer, kazni za lastnike zemljišč, ki ne odstranijo alergene rastline, kot je ambrozija, bi lahko spodbudile učinkovitejše ravnanje z invazivnimi rastlinami. Prav tako bi moralo biti dovoljeno humano odstranjevanje invazivnih živali, kot so nutrije v Ljubljanici. Ljudje pogosto ne razumejo škodljivosti invazivnih vrst in se upirajo njihovemu odstranjevanju, čeprav te vrste povzročajo uničujoče učinke na avtohtone ekosisteme. Navedimo dva primera: če bi bili pogoji povsod po svetu enaki, bi prevladovalo recimo 10-krat manj vrst, kot jih je danes. Z globalizacijo se pogoji izenačujejo, saj ljudje postajajo ključni dejavnik v večini ekosistemov, kjer s svojo prisotnostjo in navadami spreminjajo prehranjevalne verige in habitate. Še en primer: sesalci predstavljajo približno 6.400 vrst na svetu. Okoli 36 % teže sesalcev predstavljajo ljudje, medtem ko 60 % teže sesalcev predstavljajo domače živali, kot so govedo, ovce, prašiči in drugi rejni organizmi. Divji sesalci pa predstavljajo le še 4 % vse biomase sesalcev na planet. Ali je projekcija 4, 3, 2, 1, 0 [20, 21]?

Podobno škodljiv vpliv imajo invazivne vrste, kot je nutrija (Myocastor coypus, znana tudi kot močvirska podgana ali bobrovka). Preden nutrije naselijo določeno območje, tam živijo avtohtone vrste podgan, miši, rakov in drugih malih živali. Vendar ko nutrije, ki tehtajo od 5 do 10 kilogramov, pridejo na to območje, uničijo, izpodrinejo ali pobijejo vse, kar jim ne ubeži (recimo ribe). Kljub temu pa lokalno prebivalstvo pogosto protestira proti odstranjevanju nutrij, ne zavedajoč se, kakšno uničenje med avtohtonimi vrstami povzročajo te invazivne živali. Takšne napačne predstave in odpor do odstranjevanja invazivnih vrst lahko povzročijo dolgoročno škodo ekosistemom, ki so že oslabljeni zaradi drugih okoljskih pritiskov.

Kot imamo akcije čiščenja okolja, bi morali izvajati akcije čiščenja invazivnih rastlin in živali in morali bi izobraževati državljane, kaj je to smotrno varovane okolja in kaj to ni.

2,4. Aksiom: Trajnostni razvoj zahteva večji učinek z manjšo porabo energije s pomočjo naprednih tehnologij in pametne rabe virov

Trajnostni razvoj ne pomeni predvsem zategovanja pasu - zmanjševanje porabe, temveč eliminiranje nesmiselnih pristopov ter povečanje učinkovitosti s pametno uporabo virov in tehnologij, kot je umetna inteligenca (AI). Z uporabo AI, avtomatizacije in optimiziranih sistemov lahko povečamo učinkovitost in zmanjšamo porabo energije, ne da bi pri tem ogrozili razvoj [22, 23]. Namesto povečanja porabe moramo iskati rešitve, ki omogočajo večji učinek z manjšo porabo energije.

Preprost primer tega so drevesa. Drevo, zasajeno pred hišo, lahko zagotavlja senco in posledično zmanjša potrebo po hlajenju stavbe za kar 20 %. To je enostaven in naraven način za zmanjšanje porabe energije brez tehnoloških intervencij, hkrati pa z drevesom prispevamo k izboljšanju kakovosti zraka, ki ga dihamo [24].

Na globalni ravni se soočamo s hitrim izginjanjem kmetijskih površin, kar še dodatno ogroža našo sposobnost za trajnostno pridelavo hrane, predvsem pa biotsko raznolikost. Vsako leto po svetu izgubimo približno 10 milijonov hektarjev kmetijskih zemljišč zaradi različnih dejavnikov, kot so urbanizacija, širitev cest, krčenje gozdov in intenzivna kmetijska dejavnost. To je približno enako 14 milijonom nogometnih igrišč [25]. Vsako minuto posekajo za 4 nogometna igrišča gozda v Amazoniji. Kdaj bo konec – ko bomo posekali in uničili vse?

Tudi v Sloveniji je situacija zaskrbljujoča, saj vsak dan izgubimo površino enega nogometnega igrišča kmetijskih zemljišč, kar vodi v zmanjšanje prostora za pridelavo hrane in povečuje obremenitev okolja. Širitev cestne infrastrukture in gradnja novih objektov na teh zemljiščih še dodatno prispevata k izginjanju naravnih površin ter pospešujeta učinke segrevanja podnebja [26]. Takšne prakse ne samo zmanjšujejo biotsko raznovrstnost, temveč ustvarjajo tudi večje potrebe po energiji in povzročajo povečanje toplogrednih plinov [27].

Nadaljnje širjenje cestne infrastrukture in gradnja novih stavb, še posebej veletrgovin in stanovanjskih sosesk na kmetijskih zemljiščih, ne samo zmanjšuje razpoložljivo površino za pridelavo hrane, temveč tudi povečuje izpuste toplogrednih plinov in segreva klimo. Gradnja dodatnih cest in veletrgovin povečuje promet, kar vodi k večji porabi fosilnih goriv in s tem dodatno obremenjuje okolje.

Namesto širjenja teh netrajnostnih praks moramo vlagati v tehnološke inovacije in naravne rešitve, ki bodo omogočile večji učinek z manjšo porabo virov. Pametno zasnovana infrastruktura, AI v energetski učinkovitosti in trajnostne rešitve, kot je zasaditev dreves in ustvarjanje naravnih senčnih površin, lahko pripomorejo k bistvenemu zmanjšanju porabe energije ter ohranjanju naših naravnih virov.

Če pogledamo usmeritve v Sloveniji in zaključke te konference o okolju, jasno opazimo velika razhajanja. Marsikje so strokovni argumenti povsem jasni in na naši strani, pa vendar javnost in mediji tega niti ne vedo.

3 Miti o okolju in kmetijstvu

3.1. Kmetijstvo je okolju neprijazno

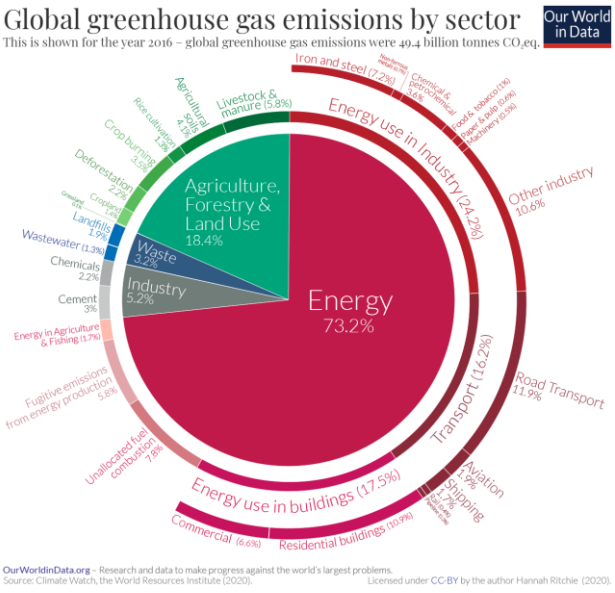
Resnica je veliko bolj kompleksna in v osnovi fundamentalno nasprotna temu mitu. Pravilno upravljano kmetijstvo prispeva k večji biotski raznovrstnosti in trajnostnemu okolju (neekološko ali nekvalitetno kmetijstvo pa seveda škodi). Kmetijske površine, kot so dobro obdelane njive in travniki, ustvarjajo raznoliko krajino, ki podpira različne vrste živali in rastlin. Pravilno upravljana polja in travniki so habitat za številne žuželke, ptice in druge prostoživeče živali, kar prispeva k izjemni biodiverziteti [28]. Na primer, v Evropi so travniki ena izmed najbolj biotsko raznovrstnih ekosistemov.

Metan, ki ga oddajajo prežvekovalci, kot so krave, ima sicer močan učinek na podnebne spremembe, vendar razpade v ozračju v približno 12 letih, medtem ko ogljikov dioksid (CO_2) ostaja v atmosferi več stoletij. To pomeni, da je vpliv metana kratkotrajen in se lahko učinkovito upravlja z uporabo novih tehnologij za zmanjšanje emisij.

Živali so naravni del ekosistema in imajo vlogo pri ohranjanju naravnih ciklov hranil. Paša živali, na primer, spodbuja rast travniških rastlin in s tem izboljšuje strukturo tal ter preprečuje erozijo. Podobno so njihovi odpadki hrana za insekte vseh vrst, katerih število se je v zadnjih 50 letih zmanjšalo za več kot polovico, kot tudi število in teža vseh divjih živali. Kmetijstvo, ki temelji na principih regenerativnega kmetovanja, izboljšuje kakovost tal, saj povečuje njihovo sposobnost zadrževanja vode in hranil. Težko je razumeti nekatere, ki se imajo za zagovornike varstva okolja, ko zagovarjajo invazivne živali in hkrati zahtevajo odstranitev domačih živali.

Strokovne raziskave kažejo, da pravilno upravljane kmetijske površine ključno prispevajo k ohranjanju biotske raznovrstnosti. Na primer, na travnikih, ki so pravilno vzdrževani, lahko uspeva do 40 različnih vrst rastlin na kvadratni meter, kar je veliko več kot v intenzivnih industrijskih monokulturah ali pozidanih površinah, ki so pogosto označene kot "puščave", kjer je prisotnih zelo malo vrst [28, 29].

Zato kmetijstvo ni okolju neprijazno – pravilno izvajano kmetijske prakse prispevajo k trajnostnemu okolju in visoki biotski raznovrstnosti, medtem ko napačne predstave o kmetijstvu pogosto izhajajo iz neustrezno vodenih praks in industrijskih metod pridelave ter napačega razumevanja, kaj je to biotska raznolikost.



Slika 1: Izvori toplogrednih plinov; tri četrtine jih prihaja iz fosilnih goriv. Vir: Hannah Ritchie (2020) - "Sector by sector: where do global greenhouse gas emissions come from?" Published online at OurWorldInData.org. Retrieved from: 'https://ourworldindata.org/ghg-emissions-by-sector' [Online Resource]

3.2. Izmed vseh tehnologij je najbolj nevarna in škodljiva ravno jedrska

Tudi tu je resnica ravno nasprotna: Jedrska energija proizvaja minimalne izpuste CO_2 v primerjavi s fosilnimi gorivi in zato predstavlja bolj trajnostno alternativo, čeprav obstajajo tveganja, povezana z odpadki. Poleg tega so nekatere trajnostne energije kot sončna in vetrna podvrženi nihanjem in so zato primerjave, tudi v tem prispevku, narejene na osnovi uravnoteženega energetskega sistema, kjer imate zadosti stalnih virov (hidro, jedrska, termo) in trajnostnih, tj. občasnih. Če ni na voljo zadosti trajnih virov, se cena električne energije zaradi shranjevanja približno podvoji ali potroji [9, 30].

Primerjava po atributih:

Cena na enoto energije (USD/kWh)

Jedrska energija: Povprečna cena proizvodnje jedrske energije znaša približno 0,09 USD/kWh. Visoki začetni stroški

izgradnje jedrskih elektrarn so kompenzirani z nizkimi obratovalnimi stroški in dolgoročno življenjsko dobo [31].

Fosilna goriva (premog, nafta, plin): Cene fosilnih goriv so odvisne od trga, vendar se cena proizvodnje električne energije giblje med 0,05 in 0,10 USD/kWh. Čeprav so začetni stroški nižji, pa fosilna goriva dolgoročno povzročajo stroške zaradi vpliva na okolje in zdravje.

Sončna energija: Stroški sončne energije so v zadnjih letih močno padli in zdaj znašajo med 0,03 in 0,06 USD/kWh, kar jo uvršča med najcenejše vire energije (če imamo osnovno energijsko zahtevo pokrito trajnostno).

Vetrna energija: Cena proizvodnje vetrne energije se giblje med 0,04 in 0,07 USD/kWh, kar jo prav tako uvršča med konkurenčne vire obnovljive energije.

Hidroenergija: Cena hidroenergije je zelo odvisna od lokacije in znaša med 0,03 in 0,05 USD/kWh, kar jo uvršča med cenovno najučinkovitejše vire energije.

Izpusti CO2 na enoto energije (gCO2/kWh)

Jedrska energija: Jedrska energija spada med najmanj emisijsko intenzivne vire, s povprečnimi izpusti CO2 okoli 12 gCO2/kWh (vključno z izgradnjo elektrarn in celotnim življenjskim ciklom).

Fosilna goriva: Premog povzroča največ izpustov, s povprečno 820 gCO2/kWh, plin povzroča približno 490 gCO2/kWh, medtem ko nafta znaša okoli 720 gCO2/kWh [32].

Sončna energija: Sončna energija prispeva približno 48 gCO2/kWh, večinoma zaradi proizvodnje in reciklaže fotonapetostnih panelov.

Vetrna energija: Vetrna energija spada med najbolj čiste vire, z izpusti okoli 11 gCO2/kWh.

Hidroenergija: Povprečni izpusti hidroenergije znašajo 24 gCO2/kWh, vendar se lahko ta vrednost poveča zaradi izpustov metana iz velikih rezervoarjev.

Potrebne površine na enoto energije (m²/kWh)

Jedrska energija: Jedrska energija zahteva najmanj prostora. Povprečna jedrska elektrarna proizvede ogromno količino energije na majhni površini – približno 1,9 m²/kWh [33].

Fosilna goriva: Premogovne in plinske elektrarne potrebujejo približno 40-100 m²/kWh, zaradi potrebe po rudarjenju in skladiščenju goriv.

Sončna energija: Solarne elektrarne zahtevajo veliko večje površine za zbiranje sončne svetlobe, s približno 25-70 m²/kWh, odvisno od učinkovitosti panelov in lokacije.

Vetrna energija: Potrebne površine za vetrne elektrarne znašajo približno 20-60 m²/kWh.

Hidroenergija: Potrebne površine za hidroelektrarne se zelo razlikujejo glede na vrsto projekta, vendar znašajo od 100 m²/kWh ali več pri velikih akumulacijskih jezerih.

Število žrtev v nesrečah na enoto energije (smrti/TWh)

Jedrska energija: Jedrska energija je kljub nekaj odmevnim nesrečam, kot so Černobil in Fukušima, statistično varna z vidika smrtnosti. Povprečje znaša 0,07 smrti/TWh, vključno z nesrečami in dolgoročnimi učinki sevanja [34].

Fosilna goriva: Premog je izredno nevaren tako zaradi nesreč v rudnikih kot zaradi dolgoročnih zdravstvenih učinkov onesnaženja. Povprečno število smrti znaša 24,6 smrti/TWh za premog in 2,8 smrti/TWh za plin.

Sončna energija: Sončna energija je zelo varna, s povprečno 0,02 smrti/TWh, večinoma zaradi nesreč pri namestitvi in vzdrževanju panelov.

Vetrna energija: Vetrna energija prav tako spada med zelo varne vire, s približno 0,04 smrti/TWh.

Hidroenergija: Čeprav hidroenergija večinoma velja za varno, lahko nesreče, kot so zrušitve jezov, povzročijo velike žrtve. Povprečno število smrti znaša 1,3 smrti/TWh, vendar lahko te nesreče lokalno povzročijo večje število smrtnih žrtev [35].

4 Diskusija

Pravilno varovanje okolja temelji na trajnostnem razvoju, kar pomeni pametno rabo virov in naprednih tehnologij, ki omogočajo večjo učinkovitost z manjšo porabo energije. Na primer, uporaba jedrske energije za proizvodnjo električne energije znatno zmanjša izpuste CO2 v primerjavi s fosilnimi gorivi in prispeva k boju proti podnebnim spremembam. Pomembno je tudi ohranjanje biotske raznovrstnosti, saj stabilni ekosistemi zagotavljajo dolgoročno odpornost na podnebne spremembe. Naravne rešitve, kot so sajenje dreves in pametno načrtovanje krajine, lahko prav tako učinkovito zmanjšujejo potrebo po energiji, kot je hlajenje stavb, ter hkrati prispevajo k izboljšanju kakovosti zraka. Pravilno varstvo okolja temelji na pametni kombinaciji naravnih in tehnoloških rešitev, ki zagotavljajo dolgoročno trajnost.

Nasprotno pa nepravilno varovanje okolja pogosto temelji na napačnih argumentih in mitih, kot je prepričanje, da so obnovljivi viri, kot sta sončna in vetrna energija, vedno boljši od jedrske energije. V resnici te rešitve zahtevajo večje površine in so manj zanesljive, ter so nekajkrat dražje, če jih je potrebno shranjevati.

Zmotno je prepričanje, da se gospodarska rast lahko nenehno povečuje, ne da bi to negativno vplivalo na okolje. Prav tako mit, da kmetijstvo škoduje okolju, izhaja iz napačnega razumevanja varovanja okolja.

Kmetijstvo prispeva k ohranjanju okolja in povečevanju biotske raznovrstnosti. Prakse, kot je regenerativno kmetovanje, spodbujajo zdravje tal, zmanjšujejo erozijo in izboljšujejo zmožnost tal za zadrževanje vode. Paša živali na travnikih, če je pravilno vodena, prispeva k naravnemu ciklu hranil, spodbuja rast rastlin in podpira raznolikost vrst. Zmanjšanje metanskih emisij s tehnološkimi inovacijami in trajnostno obdelavo zemljišč omogoča, da kmetijstvo ne le minimizira škodljive učinke, temveč aktivno prispeva k varovanju naravnih virov.

Pogosto napačno predstavljanje kmetijstva kot enega glavnih onesnaževalcev temelji na primerih neustreznih praks, kot so intenzivne monokulture in pretirana uporaba kemikalij, česar v Sloveniji skoraj ni. Vendar pa je resnica, da lahko kmetijstvo, če se izvaja trajnostno, bistveno prispeva k varovanju okolja. Travniki in kmetijske površine lahko podpirajo večjo biotsko raznovrstnost kot mnoge gozdne površine, saj ustvarjajo naravne habitate za številne rastlinske in živalske vrste. Sodobni miti o kmetijstvu, ki ga enačijo z uničevanjem okolja, ne upoštevajo pozitivnih vplivov trajnostnih kmetijskih praks, ki so ključne za ohranjanje ekosistemov.

Zelo pomembno je tudi, kako je kmetijstvo upravljano, recimo ali se zgodaj kosi travo, ali se krave nepravilno hrani itd. Tu so lahko napredni in ekološko zavedni sistemi vodenja kmetij na osnovi umetne inteligence in GPT izredno koristni tako za kmete kot za varstvo okolja. Ko smo predlagali tovrstne ideje predstavnikom oblasti, pa ni bilo prav veliko zanimanja.

V zaključku: kmetijstvo je v svoji osnovi najboljša varovalka okolja in zato bi morali okoljevarstveniki, kmetje in raziskovalci skupaj zagovarjati najboljše rešitve.

Umetna inteligenca o zeleni agendi (izvedljivost, cena in rezultati zelenega prehoda)

Jure Špiler
Ljubljana, Slovenija
jure@basic.si

ABSTRACT / POVZETEK

Dobrobit človeštva se nesmiselno povezuje z zmanjšanjem CO2 izpustov (razogljičenjem, Net Zero), kar povzroča ogromne stroške in še več prikritega onesnaženja, brez otipljivih rezultatov. Le prilagajanje spremembam v okolju je smiselno in ekonomsko učinkovito.

Samo uporaba preizkušenih obstoječih virov zanesljive energije (reke, nafta, plin, jedrska tehnologija) omogoča normalno življenje in razvoj.

S pomočjo umetne inteligence (https://www.perplexity.ai/) sem poiskal odgovore na aktualna vprašanja:

- Stroški razogljičenja (Net Zero)
- Cena hlajenja ($/°C)
- Dosedanje segrevanje in vpliv na populacijo
- Bo segrevanje zmanjšalo število ljudi?
- Zaradi mraza umre 10-krat več ljudi kot zaradi vročine
- Segrevanje 2x hitrejše od svetovnega povprečja
- Hinavščina razogljičenja
- Nasprotovanje jedrski energiji
- Okoljevarstvo kot kult
- Okoljski vidik blejskih kremšnit

KEYWORDS / KLJUČNE BESEDE

CO2, razogljičenje, prebivalstvo, energetika, plin, nafta, jedrska energija, ekonomija

OPTIONAL: ABSTRACT

Humanity's well-being is meaninglessly linked to CO2 reduction (decarbonisation, Net Zero), which entails huge costs and more hidden pollution, with no tangible results. Only adapting to environmental change is sensible and economically efficient.

Only the use of proven existing sources of reliable energy (rivers, oil, gas, nuclear technology) allows normal life and development.

With the help of artificial intelligence (https://www.perplexity.ai/).I have sought answers to the questions at hand:

- - The cost of decarbonisation (Net Zero)
- - Cost of cooling ($/°C)
- - Warming to date and impact on population
- - Will warming reduce the number of people?
- - 10 times more people die from cold than heat
- - Warming 2x faster than global average
- - The hypocrisy of decarbonisation
- - Opposition to nuclear power
- - Environmentalism as a cult
- - The environmental aspect of Bled kremšnites

OPTIONAL: KEYWORDS

CO2, decarbonisation, population, energy, gas, oil, nuclear, economics

1 Stroški razogljičenja

To je kompleksno in večplastno vprašanje, ki vključuje znatne finančne naložbe v različnih sektorjih in regijah. Tukaj je nekaj ključnih vidikov:

1.1 Ocene skupnih stroškov

Globalne naložbene zahteve: Ocenjuje se, da bo za doseganje ničelnih neto emisij od leta 2021 do 2050 potrebnih približno 110 bilijonov dolarjev globalnih kapitalskih naložb, kar je v povprečju 3,5 bilijona dolarjev letno. Ta naložba predstavlja približno 1,3 % predvidenega svetovnega BDP v naslednjih treh desetletjih [4].

Naložbe v posamezne sektorje: Velik del teh naložb, približno 70 % ali 2,4 bilijona USD letno, bi moral biti usmerjen v sektor električne energije. To vključuje naložbe v proizvodnjo električne energije brez emisij ogljika, elektroenergetska omrežja ter shranjevanje električne energije in prilagodljivost omrežja[4].

1.2 Cena na tono CO2

Cene ogljika: Stroške razogljičenja je mogoče razumeti tudi v smislu cen ogljika. Trenutne ocene kažejo, da morajo biti cene ogljika med 50 in 100 USD na tono CO2 do leta 2030, da se uskladijo s cilji Pariškega sporazuma [6]. Svetovna povprečna cena ogljika je leta 2024 znašala 32 USD na tono , kar je pod priporočenim razponom [6].

Stroški razogljičenja glede na kategorijo emisij : Stroški za razogljičenje posebnih kategorij emisij se razlikujejo. Na primer, cena zemeljskega plina je približno 3505 GBP na tono CO2e, medtem ko je za obnovljivo energijo približno 6435 GBP na tono CO2e [1].

1.3 Regionalne razlike

Cene ogljika po regijah: Pobude za določanje cen ogljika se med regijami precej razlikujejo. Evropa in Srednja Azija imata

povprečno ceno ogljika 50 USD na tono , medtem ko je cena v ZDA in Kanadi približno 48 USD na tono . Druge regije, kot sta Latinska Amerika in Karibi, imajo nižje povprečne cene, okoli 24 USD na tono [6].

Naložbene potrebe po regijah: Naložbene zahteve za doseganje ničelnih neto emisij se prav tako razlikujejo glede na regijo, na kar vplivajo obstoječa infrastruktura, politični okviri in gospodarski pogoji[4].

1.4 Izzivi in premisleki

Socialni in gospodarski vplivi: Prehod na ničelne neto emisije bo imel široke gospodarske in družbene učinke, ki bodo vplivali na povpraševanje, kapitalsko porabo, stroške in zaposlovanje v različnih sektorjih[7].

Politika in izvajanje: Učinkovita dekarbonizacija zahteva trdne politične okvire, vključno z mehanizmi za določanje cen ogljika, spodbudami za čisto tehnologijo in mednarodnim sodelovanjem za zagotovitev pravičnega in učinkovitega izvajanja[5][6].

Povzetek

Stroški razogljičenja vključujejo velike finančne obveznosti v različnih sektorjih in regijah, s precejšnjimi razlikami v cenah ogljika in naložbenih potrebah. Za doseganje globalnih ciljev razogljičenja bodo potrebna usklajena prizadevanja in strateške naložbe za uravnoteženje gospodarske rasti z okoljsko trajnostjo.

2 Stroški odstranjevanja CO2 iz ozračja

Trenutni stroški za neposredno zajemanje CO2 iz zraka so ocenjeni med 600 in 1.000 dolarjev na tono odstranjenega CO2[4][8]. Za široko uporabo tehnologije neposrednega zajemanja iz zraka (direct air capture - DAC) morajo stroški pasti pod 200 dolarjev na tono, idealno bližje 100 dolarjev na tono do leta 2050[4][9]

Raziskovalci ETH Zürich ocenjujejo, da bodo stroški leta 2050 predvidoma med 230 in 540 dolarji na tono, namesto pogosto omenjenega razpona 100-300 dolarjev[6][7].

Projekcije stroškov za posamezne DAC tehnologije do leta 2050:

- Climeworks: 280-580 dolarjev na tono
- Carbon Engineering: 226-544 dolarjev na tono
- Heirloom: 230-835 dolarjev na tono[6][8]

To je približno dvakrat več od nekaterih prejšnjih ocen[6].

Ključno za znižanje stroškov je povečanje obsega uporabe DAC, vendar je v kratkem roku potrebno več zmogljivosti, kot je trenutno načrtovano[4]. Na skupne stroške DAC vplivajo stroški posameznih komponent, stroški energije in stroški integracije[3]. Bolj dovršene komponente, kot so kompresorji, imajo manjši potencial za znižanje stroškov[8].

Kljub višjim napovedim nekatera DAC podjetja že ponujajo cene blizu ali na ravni 340 dolarjev na tono, ki je predvidena za leto 2050[4]. Utežena povprečna cena za DAC s shranjevanjem se je med letoma 2022 in 2023 znižala za 43 %, s 1.261 na 715 dolarjev na tono[4]. Nekatera podjetja trdijo, da so trenutni stroški zajemanja pod 500 ali celo 200 dolarjev na tono[4].

Čeprav se pričakuje, da se bodo stroški z razvojem tehnologije bistveno znižali, nedavne raziskave kažejo, da znižanja morda ne bodo tako dramatična, kot so upali prej. Kljub temu se zdi, da industrija DAC napreduje hitreje pri zniževanju stroškov, kot predvidevajo nekatere študije. Priporoča se nadaljnji razvoj več pristopov DAC za spodbujanje inovacij in znižanje stroškov[6][8].

2.1 Strošek odstranjevanja 1ppm CO2 iz zraka

1 ppm atmosferskega CO2 ima maso 7,76 gigaton (Gt) CO2.

- Pri ceni 100 US$ na tono bi stroški znašali 776 milijard US$.
- Po trenutnih cenah 700-1200 US$/t to pomeni 5 - 9 bilijonov US$
- Do leta 2050 se bi ta vsota prepolovila
- Trenutno je svetovni bruto domači proizvod (BDP) 101 bilijon US$

Za odstranitev 0,2% CO2 (1ppm) bi porabili 10% družbenega proizvoda

3 Stroški hlajenja ($/°C)

Na podlagi posredovanih rezultatov iskanja je težko podati natančno oceno hladilnega učinka v stopinjah Celzija na milijardo dolarjev, porabljenih za razogljičenje. Vendar pa lahko naredimo nekaj sklepov:

• Odlašanje z ukrepi za zajezitev podnebnih sprememb ima znatne gospodarske stroške. Zamuda, ki povzroči segrevanje za 3 °C nad predindustrijsko ravnjo namesto za 2 °C, bi povzročila dodatno škodo v višini 0,9 % svetovne proizvodnje, kar pomeni približno 150 milijard dolarjev samo za ameriško gospodarstvo[3].

• Obnovljivi viri energije bi lahko do leta 2050 razogljičili 90 % elektroenergetske industrije, kar bi drastično zmanjšalo emisije ogljika in prispevalo k ublažitvi podnebnih sprememb [4]. Stroški tehnologij obnovljive energije, kot sta sončna energija in veter, so se od leta 2010[4] znatno znižali.

• Ocene skupnih stroškov za odpravo podnebnih sprememb segajo od 300 milijard do 50 bilijonov dolarjev v naslednjih dveh desetletjih[5]. Ta ogromen razpon odraža negotovost in zapletenost pri določanju optimalne strategije razogljičenja.

• V scenariju IEA o neto ničelnih emisijah do leta 2050 morajo posredne emisije CO2, povezane s povpraševanjem po hlajenju prostorov, do leta 2030 pasti na približno 40 % današnje ravni [1]. To bi pomenilo, da se povprečna učinkovitost nove klimatske opreme do leta 2035 približa najboljši razpoložljivi ravni [1].

Medtem ko rezultati iskanja ne zagotavljajo natančnega kvantitativnega razmerja med stroški razogljičenja in znižanjem temperature, pa kažejo, da lahko pomembne naložbe v obnovljivo energijo, energetsko učinkovitost in zmanjšanje emisij pomembno vplivajo na omejevanje prihodnjega dviga globalne temperature.

Povzetek

Natančen hladilni učinek na porabljen dolar ostaja negotov in se razlikuje glede na izvedene posebne ukrepe za dekarbonizacijo.

4 Dosedanje segrevanje in vpliv na populacijo

4.1 Globalno povečanje temperature

• Od leta 1880 se je povprečna površinska temperatura Zemlje dvignila za 0,07°C na desetletje.

• Stopnja povečanja temperature se je od leta 1981 več kot podvojila na 0,18°C na desetletje.

• Povprečne površinske temperature so v zadnjih letih dosledno presegale 1,5°C nad predindustrijskimi vrednostmi.

4.2 Rast prebivalstva

• Svetovno prebivalstvo je zraslo z okoli 1,6 milijarde leta 1900 na 8,1 milijarde leta 2024.

• Stopnja rasti prebivalstva je dosegla vrhunec 2,2% letno leta 1963 in se od takrat znižala na približno 1,1% letno.

4.3 Vplivi podnebnih sprememb na prebivalstvo

• Podnebne spremembe vplivajo na smrtnost in življenjske pogoje preko neposrednih vplivov ekstremnih temperatur in posrednih vplivov, ki jih posredujejo okoljski in družbeni sistemi.

• Ogrožajo prehransko varnost, oskrbo s sladko vodo in zdravje ljudi.

• Dvig morske gladine ogroža stotine milijonov ljudi v obalnih območjih.

• Podnebne spremembe lahko prisilijo ljudi k migraciji, z ocenami do več sto milijonov podnebnih migrantov do leta 2050.

4.4 Rast prebivalstva kot gonilnik podnebnih sprememb

• Rast prebivalstva skupaj s povečano potrošnjo običajno povečuje emisije toplogrednih plinov.

• Vpliva tudi na sposobnost Zemlje, da se upre podnebnim spremembam in absorbira emisije, na primer s krčenjem gozdov, ko se zemljišča spreminjajo v kmetijske površine za prehrano rastočega prebivalstva.

4.5 Demografski dejavniki in podnebna ranljivost

• Ljudje v revnih regijah, kljub temu da malo prispevajo k emisijam, so najbolj ranljivi za vplive podnebnih sprememb.

• Visoke stopnje revščine in socialne neenakosti povečujejo ranljivost za ekstremne vremenske pojave, vodni stres in izzive pri pridelavi hrane.

4.6 Populacijska dinamika in podnebna politika

• Upočasnitev rasti prebivalstva s pravičnimi ukrepi, kot je povečanje dostopa do načrtovanja družine, bi lahko igrala ključno vlogo pri blaženju podnebnih sprememb.

• Vendar lahko tudi v planih z nizko rastjo prebivalstva ogljično intenzivna gospodarska rast še vedno povzroči visoke emisije.

4.7 Zgodovinski kontekst

• Pospeševanje podnebnih sprememb sovpada z obdobji hitre industrializacije in rasti prebivalstva, zlasti od sredine 20. stoletja.

Povzetek

Čeprav naraščajoče temperature niso neposredno povzročile rasti prebivalstva, so začele vplivati na človeške populacije na različne načine. Hkrati je rast prebivalstva prispevala k podnebnim spremembam, kar ustvarja kompleksno povratno

zanko med demografskimi trendi in okoljskimi spremembami. Odnos med podnebnimi spremembami in prebivalstvom je večplasten in vključuje vprašanja emisij, ranljivosti, prilagajanja in strategij blaženja.

5 Ali segrevanje zmanjšuje število ljudi?

Dvig globalnih temperatur za 2 stopinji Celzija verjetno ne bo neposredno znižal svetovnega prebivalstva, lahko pa ima pomembne posredne učinke, ki lahko upočasnijo rast prebivalstva ali celo povzročijo upad prebivalstva v določenih regijah. Tukaj so ključne točke:

• Smrti zaradi vročine : višje temperature bodo povečale tveganje za bolezni in umrljivost zaradi vročine, zlasti med ranljivimi skupinami prebivalstva, kot so starejši, otroci in osebe z že obstoječimi zdravstvenimi težavami. To bi lahko povzročilo višje stopnje smrtnosti na prizadetih območjih.

• Vplivi na zdravje : Podnebne spremembe lahko tudi poslabšajo kakovost zraka, širijo nalezljive bolezni ter motijo oskrbo s hrano in vodo, kar dodatno poveča zdravstvena tveganja in umrljivost.

• Zmanjšanje pričakovane življenjske dobe : V regijah, ki so jih močno prizadele podnebne spremembe, se lahko pričakovana življenjska doba skrajša zaradi skupnih učinkov toplotnega stresa, podhranjenosti in bolezni. To bi lahko upočasnilo rast prebivalstva ali celo povzročilo upad prebivalstva.

• Podnebni begunci: Dvig morske gladine, ekstremni vremenski pojavi in degradacija okolja bi lahko povzročilo povečano preseljevanje. S tem bi se povečal pritisk na vire in infrastrukturo sprejemnih območji ter povzročilo socialno in gospodarsko nestabilnost.

• Konflikti in nemiri: S podnebjem povezano razseljevanje in pomanjkanje virov lahko prav tako prispevata k konfliktom, ki lahko dodatno destabilizirajo prizadete regije in povzročijo upad prebivalstva.

• Družbeno-ekonomski vplivi: gospodarske in družbene motnje, ki jih povzročajo podnebne spremembe, kot je zmanjšana kmetijska produktivnost, bi lahko povzročile večjo revščino in nestabilnost. To lahko povzroči zmanjšanje stopnje rodnosti, saj imajo ljudje manj otrok zaradi gospodarske negotovosti ter zmanjšanega dostopa do zdravstvenega varstva in izobraževanja.

5.1 Omejitve

Pomembno je omeniti, da čeprav lahko podnebne spremembe prispevajo k upadu prebivalstva v določenih regijah, je malo verjetno, da bodo v bližnji prihodnosti bistveno zmanjšale svetovno prebivalstvo. Na rast prebivalstva vplivajo številni zapleteni dejavniki, splošni vpliv podnebnih sprememb na število svetovnega prebivalstva pa ostaja negotov.

Povzetek

Čeprav ni pričakovati, da bi dvig globalnih temperatur za 2 stopinji neposredno zmanjšal svetovno prebivalstvo, bi lahko povzročil povečano umrljivost, krajšo pričakovano življenjsko dobo, razseljevanje in nižjo stopnjo rodnosti v močno prizadetih regijah. Blaženje podnebnih sprememb in prilagajanje njihovim vplivom bo ključnega pomena za zmanjšanje teh možnih vplivov na prebivalstvo.

Medicinska revija The Lancet ocenjuje, da je dostop do klimatskih naprav v letu 2019 preprečil skoraj 200.000 smrti med ljudmi, starimi 65 let ali več[9].

6 Zaradi mraza umre 10-krat več ljudi kot zaradi vročine

Čeprav je res, da je v preteklosti število smrti zaradi mraza znatno preseglo smrti zaradi vročine, se dinamika zaradi podnebnih sprememb spreminja. Tukaj so ključne točke v zvezi

z vplivom naraščajočih temperatur na stopnjo umrljivosti in morebitne posledice za svetovno prebivalstvo:

6.1 Trenutni trendi smrti zaradi temperature

• Smrti zaradi mraza v primerjavi z vročino : Študije kažejo, da na svetu zaradi mraza umre približno devetkrat več kot zaradi vročine. Študija, objavljena v »The Lancet Planetary Health«, je pokazala, da je v zadnjih dveh desetletjih izpostavljenost mrazu predstavljala veliko večino smrtnih primerov, povezanih s temperaturo, pri čemer je bilo približno 8,5 % smrti pripisanih mrazu in samo 0,9 % vročini[1][2][4].

• Spreminjanje vzorcev : Čeprav trenutno prevladujejo smrti zaradi prehlada, se trend spreminja. Smrti zaradi vročine zaradi podnebnih sprememb naraščajo, število smrti zaradi mraza pa se zmanjšuje. Ta premik nakazuje, da se bo ravnovesje v prihodnosti lahko nagnilo k večjemu številu smrtnih žrtev, povezanih z vročino [1][4][5].

Posledice naraščajočih temperatur

• Povečana smrtnost zaradi vročine : Ko se temperature dvignejo, zlasti v ranljivih regijah, se pričakuje, da se bo število smrti zaradi vročine povečalo. To je še posebej zaskrbljujoče za prebivalstvo na območjih, ki niso vajena ekstremne vročine, in kjer so prilagoditveni ukrepi morda nezadostni[1][4].

• Potencialni vpliv na prebivalstvo : Čeprav celotno število svetovnega prebivalstva morda ne bo takoj upadlo zaradi povečanega števila smrti, povezanih z vročino, bi lahko v nekaterih regijah prišlo do znatnega povečanja umrljivosti in upočasnilo rast prebivalstva ali povzročilo lokalno zmanjšanje. Ranljivo prebivalstvo, zlasti na območjih z nizkimi dohodki, je lahko nesorazmerno prizadeto, kar še poslabša obstoječe zdravstvene razlike in potencialno vodi do večjih migracijskih pritiskov[1][2][5].

• Dolgoročne projekcije : Ker se podnebne spremembe še naprej odvijajo, bi lahko vse večja razširjenost smrti zaradi vročine sčasoma uravnotežila ali presegla smrt zaradi mraza, zlasti če se ne izvajajo prizadevanja za ublažitev. To bi lahko vodilo do višjih splošnih stopenj umrljivosti in vplivalo na populacijsko dinamiko skozi čas[2][4].

Povzetek

Če povzamemo, čeprav število smrti zaradi mraza trenutno znatno presega število smrti zaradi vročine, podnebne spremembe spreminjajo to pokrajino. Pričakuje se, da bo dvig globalnih temperatur povečal smrtnost zaradi vročine, kar bi lahko imelo globoke posledice za zdravje in dinamiko prebivalstva, zlasti v ranljivih regijah. Takojšnje ukrepanje za ublažitev podnebnih sprememb je ključnega pomena za preprečitev teh neugodnih rezultatov.

7 Segrevanje 2x hitrejše od svetovnega povprečja

Samo nekaj področij je, kjer se to res dogaja

• Arktika, zlasti polotok Tajmir v Rusiji, se segreva 2,5- do 2,8-krat hitreje od svetovnega povprečja. V zadnjih 10 letih so tamkajšnje temperature narasle za 0,8 °C do 1,2 °C (1,4 °F do 2,1 °F) hitreje od svetovnega povprečja [4].

• Rusko ozemlje se na splošno segreva skoraj dvakrat hitreje od svetovnega povprečja kopnega – pri 0,51 °C (0,91 °F) na desetletje v primerjavi z 0,295 °C (0,531 °F) globalno nad kopnim[4].

• Antarktika se segreva dvakrat hitreje od svetovnega povprečja, s približno 20–50 % večjim segrevanjem od ocen iz podnebnih modelov. To temelji na rekonstrukciji temperatur na Antarktiki v preteklem tisočletju z uporabo zapisov ledenih jeder [5].

• Podnebni modeli predvidevajo, da se bo pas južne Azije, ki se razteza od Perzijskega zaliva preko Indije in Kitajske, segreval hitreje kot skoraj kjer koli drugje na Zemlji v različnih scenarijih podnebnih sprememb. V tej regiji živi več kot milijarda ljudi[3].

Povzetek,

Arktika, Rusija, Antarktika in deli južne Azije se soočajo z dvigi temperature, ki so približno dvakrat višji od svetovnega povprečja, pri čemer se Arktika segreva najhitreje in je dvig temperature skoraj trikrat višji. Hitro segrevanje v teh regijah je velika skrb zaradi velike populacije v južni Aziji in možnih vplivov segrevanja Arktike in Antarktike na podnebni sistem.

Ali se res 2x hitreje segreva tudi Slovenija [9]?

8 Hinavščina razogljičenja

Koncept hinavščine v prizadevanjih za razogljičenje je večplastno vprašanje, ki vključuje neskladja med navedenimi zavezami za zmanjšanje emisij ogljika in ukrepi, ki jih sprejmejo posamezniki, korporacije in države. V diskurzu o podnebnih spremembah in dekarbonizaciji je izpostavljenih več vidikov te hinavščine.

8.1 Razlika med bogatimi in revnimi narodi

Bogate države, ki so v preteklosti največ prispevale k emisijam toplogrednih plinov, pogosto spodbujajo podnebne politike, ki nesorazmerno bremenijo države v razvoju. Mehanizmi, kot je mehanizem Evropske unije za prilagajanje meja ogljika, so na primer kritizirani zaradi zaostrovanja globalnih neenakosti z nalaganjem stroškov revnejšim državam, medtem ko bogate države še naprej porabljajo blago, proizvedeno z visokimi okoljskimi stroški[2][7].

• Hinavščino dodatno poudarja dejstvo, da bogate države pogosto selijo energetsko intenzivne industrije v države v razvoju, pri čemer dejansko izvažajo emisije, medtem ko še naprej porabljajo nastale izdelke [2].

8.2 Individualna in korporativna dejanja

• Posameznikom in korporacijam pogosto očitajo hinavščino, ko se zavzemajo za podnebne ukrepe, medtem ko se ukvarjajo z ogljično intenzivnimi dejavnostmi. To vključuje uporabo fosilnih goriv za potovanja ali proizvodnjo ob javnem spodbujanju trajnosti[3][4].

• Podjetja so včasih obtožena zelenega pranja – podajanja zavajajočih trditev o svojih okoljskih prizadevanjih, da bi bila videti bolj trajnostna, kot so. Vendar pa nekatere študije kažejo, da si številna podjetja, ki se ukvarjajo s trgi ogljičnih kreditov, resnično prizadevajo zmanjšati svoje emisije, čeprav se razpravlja o učinkovitosti in iskrenosti teh prizadevanj [6].

8.3 Sistemska odgovornost proti individualni odgovornosti

• Kritiki trdijo, da osredotočanje na posamezna dejanja, kot je sramotenje bega, preveč poenostavlja vprašanje in ne obravnava sistemskih sprememb, potrebnih za boj proti podnebnim spremembam. Zanašanje na fosilna goriva je za posameznike pogosto neizogibno zaradi trenutne infrastrukture in gospodarskih sistemov, zaradi česar so obtožbe osebne hinavščine manj vplivne[3][5].

• Obstaja poziv k sistemskim spremembam, ki omogočajo bolj trajnostne odločitve, s poudarkom na potrebi po večjih strukturnih reformah namesto zgolj osredotočenju na posameznikovo vedenje[4].

8.4 Podnebne konference in politične zaveze

• Mednarodne podnebne konference pogosto razkrivajo vrzel med zavezami in dejanji. Razvite države so bile kritizirane zaradi zastoja pri finančni podpori za podnebno ranljive države in nezmožnosti ustreznega obravnavanja izgube in škode [8].

• Kljub obljubam, da bodo zmanjšale emisije in podprle globalna podnebna prizadevanja, številne države še naprej izvajajo projekte fosilnih goriv doma, kar poudarja nepovezanost med njihovo mednarodno retoriko in domačo politiko [8].

8.5 Nasprotovanje jedrski energiji

• Nasprotovanje jedrski energiji ob hkratnem zagovarjanju zmanjšanja emisij ogljika je nedosledno, saj bi jedrska energija lahko imela pomembno vlogo pri razogljičenju proizvodnje električne energije. [9][10]

• Na protijedrska stališča nekaterih okoljskih skupin vpliva financiranje s strani donatorjev z izrecno protijedrskimi programi in ne zgolj okoljska vprašanja. [9]

• Kritiki trdijo, da je zaradi zavračanja jedrske energije veliko težje doseči podnebne cilje, saj se s tem odstrani preverjena možnost nizkoogljične tehnologije.[9][10]

Povzetek

Hinavščina prizadevanj za razogljičenje je zapleteno vprašanje, ki vključuje tako dejanja posameznikov kot politike držav. Poudarja potrebo po resničnih zavezah in sistemskih spremembah za učinkovito reševanje podnebnih sprememb in zmanjšanje svetovnih emisij ogljika. Najhujše pa je nasprotovanje jedrski energiji, ki zaenkrat edina zagotavlja zanesljivo in čisto energijo.

9 Okoljevarstvo kot kult

O pojmu okoljskega gibanja kot o "kultu" se je razpravljalo v različnih kontekstih, pogosto s strani kritikov, ki trdijo, da nekateri vidiki okoljskega gibanja kažejo značilnosti, podobne tistim pri verskem ali kultu podobnem vedenju. Tukaj je nekaj ključnih točk:

9.1 Značilnosti kultnega okoljevarstva

• Apokaliptične pripovedi : Kritiki trdijo, da imajo nekateri okoljevarstveniki apokaliptični pogled na svet in napovedujejo katastrofalne rezultate, če ne bodo sprejeti takojšnji in drastični ukrepi. To odraža napovedi sodnega dne, ki so pogosto povezane s kulti [4][6].

• Moralni puritanizem in ekstremizem : Okoljevarstveno gibanje je včasih opisano kot izkazovanje moralnega puritaizma, z ekstremnimi dejanji aktivistov, da bi opozorili na svoje vzroke. Ta dejanja lahko vključujejo moteče proteste in simbolična dejanja vandalizma, ki veljajo za izraze fanatične predanosti cilju [4].

• Verski jezik in prakse : Za okoljevarstvo včasih pravijo, da prevzema verski jezik in prakse, kot je ideja o "ogljičnih grehih" in potreba po "pokori" z izravnavo ogljika. To je mogoče razumeti kot analogno verski izpovedi in odkupni daritvi [3].

• Protičloveški pogled na svet : Nekateri kritiki trdijo, da se lahko radikalno okoljevarstvo nagiba k protičloveški perspektivi, ki na človeštvo gleda kot na grožnjo planetu. Ta perspektiva lahko zagovarja nadzor nad populacijo ali prikazuje ljudi kot "vrsto plevela", kar lahko razumemo kot razvrednotenje človeškega življenja[2][7].

• Sovražnost do drugače mislečih : Okoljevarstvo je včasih kritizirano zaradi nestrpnosti do nasprotujočih si pogledov, označevanja skeptikov kot "zanikovalcev" in odvračanja od odprte razprave. To odraža, kako kulti pogosto zatirajo nestrinjanje, da bi ohranili enoten sistem prepričanj[3].

9.2 Protiargumenti

Čeprav te kritike obstajajo, je pomembno opozoriti, da vodilno (mainstream) okoljevarstvo ni monolitno in vključuje širok spekter prepričanj in praks. Številni okoljevarstveniki se osredotočajo na dokazih temelječe pristope k obravnavanju podnebnih sprememb in spodbujanju trajnosti. Trdijo, da nujnost okoljskih vprašanj zahteva odločno ukrepanje in da je prikaz okoljevarstva kot kulta napačna opredelitev, ki spodkopava upravičene skrbi glede ekološke degradacije in podnebnih sprememb.

Povzetek

Medtem ko nekateri kritiki dojemajo nekatere elemente okoljevarstva kot kultne, to stališče ni splošno sprejeto in mu pogosto oporekajo tisti, ki vidijo okoljsko zagovorništvo kot racionalen in nujen odgovor na pereče globalne izzive.

10 Okoljski vidik blejskih kremšnit

Izlet do Blejskega jezera, da bi uživali v lokalni specialiteti , kremšnitah , ima številne okoljske vidike, ki jih je vredno raziskati. Blejsko jezero je naravna znamenitost, ki obiskovalce privablja s svojo lepoto in edinstvenim ekosistemom. Vendar lahko povečan obisk povzroči preobremenitev okolja, kar lahko vpliva na kakovost vode in biotsko raznovrstnost. Pomembno je, da obiskovalci ravnajo odgovorno, spoštujejo naravo in se zavedajo svojega vpliva na okolje.

Priprava kremšnit na Bledu pogosto vključuje lokalne sestavine, ki lahko pozitivno vplivajo na okolje. Uporaba lokalno pridelanih sestavin zmanjšuje ogljični odtis, povezan s prevozom hrane. Poleg tega spodbujanje lokalnih kmetov in proizvajalcev prispeva k trajnostnemu razvoju regije. Paziti pa je treba tudi na embalažo in odpadke, ki nastanejo med potovanjem, saj lahko nepravilno ravnanje dodatno obremenjuje okolje.

Priljubljenost blejskih kremšnit odpira tudi vprašanje trajnosti turizma. Obiskovalce je treba ozaveščati o pomenu ohranjanja naravnih virov in kulturne dediščine. Dejavnosti, kot so organizirani izleti in delavnice o trajnostnem turizmu, lahko pripomorejo k ozaveščanju o okoljskih izzivih in spodbujajo odgovorno vedenje . Tako lahko izlet na kremšnite na Blejsko jezero postane ne le kulinarično doživetje, ampak tudi priložnost za izobraževanje in aktivno sodelovanje pri varovanju okolja.

Slika 4: Blejska kremšnita
https://the-slovenia.com/en/slovenia/blejska-kremsnita-blejska-kremna-torta

10.1 Izračun ogljičnega odtisa

Ogljični odtis potovanja na Blejske kremšnite je odvisen od številnih dejavnikov, kot so prevoz, hrana in namestitev. Če upoštevamo, da se obiskovalec pripelje iz Ljubljane z avtom, poje eno kremšnito in se vrne domov, lahko ocenimo, da je njegov ogljični odtis približno 20,4 kg CO2e.

10.2 Emisije v prometu:

Razdalja LJ-Bled 50 km, skupaj torej 100 km.

Izpust prevoza z avtomobilom: 200g CO2 / km * 100 km = 20 kg CO2.

• Izlet na Bled proizvede 20kg CO2.

10.3 Izpust CO2 kremšnite

Sestavine 1 kg kremšnite: listnato testo: 300 g , vaniljev puding: 400 g , sladka smetana: 300 g

Listnato testo: 2,5 kg CO2 / kg × 0,3 kg = 0,75 kg CO2
Vaniljev puding: 1,5 kg CO2 / kg × 0,4 kg = 0,6 kg CO2
Sladka smetana: 3,0 kg CO2 / kg × 0,3 kg = 0,9 kg CO2

Ogljični odtis znaša 2,25 kg CO2 na kilogram kremšnit.

Velikost kremšnite je 7 cm x 7 cm in tehta 180 gramov.

• Ogljični odtis kremšnite je 0,41 kg CO2 / porcijo, kar ustreza 10 uram človeškega dihanja[9] in 1/50 izleta na Bled.

11 Pričakovan rezultat razogljičenja

• Vreme bo enako.
• Demontirali bomo kapitalizem in odpravili fosilna goriva.
• Pa kremšnitam smo se bomo odpovedali ;=(((

Radon v stavbah in kakovost bivanja

Radon in buildings and quality of life

Matjaž Valenčič
Zveza ekoloških gibanj Slovenije-ZEG
Krško, Slovenija
matjaz.valencic@gmail.com

Povzetek

V stavbah, ki niso ustrezno zgrajene ali sanirane, se nabira radon, zdravju nevaren žlahtni plin brez barve, vonja in okusa.

Področje radona v stavbah pokrivajo ministrstva za zdravje, za energijo, za prostor, za graditev … Čeprav so vsa ministrstva aktivna na področju preprečevanja radona v stavbah, niso medresorsko usklajena. Prepogosto se zgodi, da občani prejmejo nasprotujoče si informacije, zato se celo dogaja, da se po energetski sanaciji stavb pojavi radon v bivalnih prostorih.

V Sloveniji merijo radon v javnih stavbah od leta 1990, v stanovanjskih stavbah pa od 2018. Žal so stanovalci premalo informirani o nevarnosti radona, zato je potrebna proaktivna komunikacija za ozaveščanje prebivalstva.

Prebivalstvo in stroko je treba seznaniti o nevarnostih radona v stavbah in predlagati izvedbo ukrepov, ki preprečujejo vdor radona v stavbah.

Ključne besede

radon v stavbah, energetska sanacija, protiradonska sanacija, radonvednost

Abstract

In buildings that are not properly constructed or rehabilitated, radon, a colorless, odorless, and tasteless noble gas that is hazardous to health, accumulates.

The field of radon in buildings is covered by the ministries responsible for health, energy, space, construction... Although all ministries are active in the field of radon prevention in buildings, they are not interdepartmental coordinated. It happens too often that citizens receive conflicting information, which is why it even happens that radon appears in living spaces after energy renovation of a building.

In Slovenia, radon has been measured in public buildings since 1990, and in residential buildings since 2018. Unfortunately, residents are insufficiently informed about the danger of radon, so proactive communication is needed to raise awareness among the population.

It is necessary to inform the population and the profession about the dangers of radon in buildings and propose the implementation of measures to prevent the ingress of radon in buildings.

Optional: Keywords

radon in buildings, energy rehabilitation, anti-radon rehabilitation, radon knowledge

Beseda »žlahten« naj ne zavede. Čeprav ta beseda pomeni nekaj imenitnega, sodeč po slovarju: žlahtna kapljica, žlahtni kamen, žlahtna plesen, žlahtna gospoda … je radon zdravju nevaren plin.

SSKJ²
žláhten -tna -o prid., žláhtnejši (á)
1. knjiž. *plemenit, izbran:* žlahten človek, mislec / žlahten značaj; biti žlahtnega srca / žlahtni cilji; žlahtne misli / žlahten okus kave / žlahtno vino / žlahtni komedijant od 1992 *igralec, ki na festivalu Dnevi komedije dobi nagrado za najboljšo komično vlogo*

Slika 2 Beseda "žlahten" ima raznolik pomen.

V kemiji pomeni beseda »žlahten« nekaj drugega. Žlahtni plini, včasih imenovani **inertni plini**, imajo svojevrstno mesto v periodnem sistemu. Vsi žlahtni plini, tudi radon (Rn), so znani po tem, da nimajo barve, vonja in okusa. So nevnetljivi, v standardnih pogojih izjemno stabilni.

Radon je kemijski element z vrstnim številom 86 in atomskim masnim številom 222, pri čemer je treba omeniti, da obstaja mnogo različnih izotopov radona. Najbolj dolgoživ izotop radona je ^{222}Rn z razpolovno dobo 3,82 dni. Ostali izotopi imajo razpolovno dobo nekaj minut ali manj; zaradi kratke razpolovne dobe in ker večinoma ti izotopi ne razpadajo z **α** razpadom, ostalih izotopov ne obravnavamo v kontekstu nevarnosti za zdravje.
Radon je element VIII. valentne skupine. Spada med žlahtne pline in tvori enoatomne molekule. Zaznamo ga predvsem zaradi radioaktivnega razpada, z merilnimi napravami.

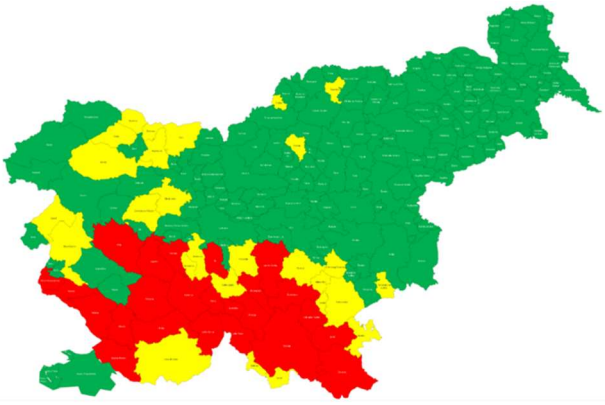
Radon sta odkrila Ernest Rutherford in Friderick Soddy leta 1900. Je najtežji element skupine žlahtnih plinov, je radioaktiven in nastaja pri radioaktivnem razpadu radija.
Še zanimivost. Plin radon nastane iz trdne snovi (radija) v zemljini, kot plin vstopa v stavbe in tam razpade v trdne snovi, ki so radioaktivne.

Za zdravje so nevarni radonovi kratkoživi razpadni produkti. To so kovine, ki v zraku tvorijo radioaktivne aerosole, nanodelce. Med dihanjem se radioaktivni aerosoli nalagajo na stenah dihalnih poti. Od tam sevajo in povzročajo poškodbe tkiva. Mednarodna agencija za raziskovanje raka (IARC) radon in njegove razpadne produkte uvršča med snovi, ki so rakotvorne za človeka (skupina 1).

Radon in njegovi razpadni produkti povzročajo pljučnega raka. Svetovna zdravstvena organizacija (WHO) je ugotovila, da se ob povišani koncentraciji radona za 100 Bq/m^3 tveganje za pljučnega raka poveča za 8 %. Tveganje za bolezen in smrt zaradi pljučnega raka pri povišanih koncentracijah radona je večje pri kadilcih kot nekadilcih. Ocenjujejo, da je vsak deseti rak na pljučih posledica radona oziroma njegovih razpadnih produktov. (7)

2 Vir in vstop radona v stavbo ter dejavniki, ki vplivajo na raven radona v stavbi

Največji izvor radona v bivalnem okolju predstavlja zemljina pod stavbo, manj pa gradbeni material, voda in plin za ogrevanje. Radon je v zaprtih prostorih, v katere prodira skozi slabo izolirana tla in vodovodna ter druga omrežja v stavbi, ki so v stiku z zemljino. Vzrok povišanih koncentracij radona so kamninska podlaga, letni čas, nadstropje v stavbi in tesnjenje oken. Največji vpliv na koncentracijo radona v stavbi ima kamninska podlaga.



Slika 3: Radonski zemljevid Slovenije (8)

Na podlagi do zdaj izvedenih meritev koncentracij radona v Sloveniji in podatkov o geološki sestavi tal so določena območja, kjer je več radona (na zemljevidu obarvano rdeče).
Dodatne meritve se izvajajo tudi na območjih občin, kjer je radon pričakovan (na zemljevidu obarvano rumeno).

Vendar se radon lahko pojavi tudi v stavbah na zelenem področju. V nekaterih ljubljanskih vrtcih in

šolah so izmerili povišane koncentracije radona in jih sanirali (9), pa so te stavbe na zelenem področju.

Za preprečevanje pojava radona v stavbah so preventivni protiradonski ukrepi potrebni tudi na zelenem radonskem področju.

A: obstoječe stavbe: Ukrepi za znižanje radona v obstoječih stavbah

V vsaki stavbi predlagamo zaščitno detekcijo koncentracije radona.

Trenutno veljavna zakonodaja določa, da je dopustna koncentracija radona v zraku bivalnega okolja pod 300 Bq/m^3. Če je mejna vrednost prekoračena, je treba začeti sanacijo radona v stavbi. Raziskave kažejo, da 1/3 slovenskih domov presega zgoraj navedeno mejno vrednost.

Zakonsko določena mejna vrednost koncentracije radona v zraku bivalnega okolja pomeni, da če meritve pokažejo vrednosti pod 300 Bq/m^3, zakonodaja ne predpisuje nujnih ukrepov. Vendar pa je pomembno poudariti:

- 300 Bq/m^3 ni varnostna meja, temveč meja, pri kateri se priporoča začetek sanacije. Že pri nižjih koncentracijah radona obstaja povečano tveganje za nastanek raka na pljučih.
- Svetovna zdravstvena organizacija (WHO) priporoča, da se prizadevanja za zmanjšanje koncentracije radona začnejo že pri vrednostih pod 100 Bq/m^3. To je še posebej pomembno v prostorih, kjer se zadržujejo otroci in občutljive skupine prebivalstva.

Izbira ukrepov naj temelji na velikosti preseženih vrednosti radona in njeni oceni vpliva na zdravje stanovalcev. Najučinkovitejši ukrep je kakovosten gradbeni poseg na talni plošči, saj z njim omejimo vir povišanih koncentracij radona v stavbi. Prezračevanje prostorov in zatesnitev vidnih razpok ter špranj v tleh in stenah, ki mejijo na zemljino, ter instalacijskih vodov sta primerna pri majhnih preseganjih dovoljenih vrednosti, sicer sta le začasna ukrepa.

Pred izvedbo vseh gradbenih ukrepov, ki bi lahko povečali koncentracijo radona v stavbi, svetujemo radonske meritve in izbor tistih ukrepov, ki znižajo prisotnost radona. Zlasti skrb vzbujajoči so nestrokovni ukrepi ob energetskih sanacijah, tesnitvi stavbe, menjavi oken, vgradnji prezračevalnih naprav z izmenjujočim delovanjem, izolaciji fasade, izdelavi prizidkov, tlakovanju dvorišč … Ti ukrepi praviloma povečajo prisotnost radona v prostorih in so, iz tega vidika, škodljivi.

Izvedba protiradonske sanacije obstoječih stavb je določena v Pravilniku (4).

- Kot gradbeni poseg za zmanjšanje izpostavljenosti radonu iz uredbe, ki ureja nacionalni radonski program, se šteje vgradnja aktivnega sistema za prezračevanje zemljine pod talno konstrukcijo.
- Ne glede na prejšnji odstavek je dopustna izvedba pasivnega sistema, če se z njim lahko zagotovi referenčna raven.
- Kot dodaten ukrep k aktivnemu sistemu prezračevanja zemljine se lahko izvede tudi tesnjenje oboda talne konstrukcije in prebojev skozi talno ploščo ter tesnjenje tlorisne površine z radonsko zaporno folijo.

B: nove stavbe: Ukrepi za preprečevanje radona pri projektiranju in izvedbi novogradenj

Zakonodaja določa, da morajo biti stavbe projektirane, grajene in vzdrževane tako, da je koncentracija radona v delovnih in bivalnih prostorih čim nižja in da ni presežena referenčna raven. Območje Republike Slovenije je razdeljeno na dve območji, in sicer na radonsko območje in zeleno območje.

- Na radonskem področju: Projektiranje in gradnja novih stavb na radonskem območju se zagotovi s prezračevanjem zemljine pod talno konstrukcijo stavbe ali s popolnim tesnjenjem med zemljino in notranjim zrakom z radonsko zaporno folijo. Kot prezračevanje zemljine se štejejo tudi arhitekturne rešitve, ki zagotavljajo zadostno prezračevanje prostorov, ki so v stiku z

zemljino tako, da ni presežena referenčna raven. Če pasivno prezračevanje zemljine ne zadošča, se vgradi aktivno prezračevanje.

- Na zelenem področju: Projektiranje in gradnja novih stavb na zelenem območju je določeno enako kot na radonskem področju.

3 Prezračevanje prostorov, popularen, a dvomljiv ukrep

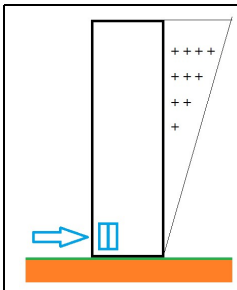
Ukrepi za znižanje koncentracije radona v stavbah so zelo različni (6). Ob pripravi projekta sanacije stavbe je treba upoštevati značilnosti objekta, temeljenje in podkletenost zgradbe, propustnost tal pod osnovno ploščo, in poiskati mesta, kjer radon vstopa v zgradbo. Vstopna mesta določimo s posebnimi instrumenti, ki merijo trenutne koncentracije radona. Čeprav velja splošno prepričanje, da koncentracijo radona v prostorih znižamo s prezračevanjem prostorov, je ta ukrep dvomljiv. Vendar pa tudi ureditev prezračevalnega sistema prostorov le malo zniža koncentracije (običajno 20-30 %). Prezračevalni sistemi, ki v zgradbah ustvarjajo dodaten podtlak, lahko privedejo tudi do nasprotnega učinka in se koncentracija radona v prostorih zviša. Povečano prezračevanje prostorov ali vzdrževanje stalnega nadtlaka v stavbi proti zemljini sta ukrepa, ki sta lahko primerna, če je prezračevanje intenzivno, z nadtlakom. Vendar sta energetsko potratna in ju stroka ne priporoča pri splošnem reševanju težave povišanega radona,

4 Napačno protiradonsko prezračevanje

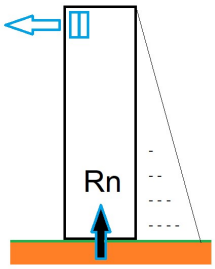
Prezračevanje pomeni izmenjavo zraka. Čist zunanji zrak vstopa v prostor, notranji pa izstopa in odnese vsa onesnažila. Izmenjava je lahko samodejna, zaradi fizikalnih lastnosti zraka ali mehanska, s prezračevalno napravo. Ne glede na način izmenjave lahko nastane v prostoru nadtlak ali podtlak. Iz vidika izmenjave zraka je vseeno, če je prezračevanje nadtlačno ali podtlačno, glede ogroženosti z radonom pač ni.

Premikanje radona skozi zemljino v stavbo je predvsem konvektivno, posledica tlačnih razlik med plinom v zemljini in tlakom v prostorih, ki ležijo nad zemljino. Neprimerno prezračevanje celo poveča koncentracijo radona v stavbah!

V stavbah je večji del leta topleje kot zunaj, zato so tlačne razmere v stavbah odvisne tudi od mesta oziroma višine netesnosti stavbe. Stare stavbe so bile praviloma netesne povsod, zlasti pri vseh okenskih odprtinah, zato je bil zračni tlak v celotni stavbi izenačen s tlakom zunanjega zraka oziroma tlaka v zemljini, možnost vdiranja radona v stavbe je bila majhna.



Slika 4 Netesnost spodaj, stavba je v nadtlaku, možnost vdora radona je majhna.



Slika 5. Netesnost zgoraj, stavba je v podtlaku, radon intenzivno vstopa.

V kurilni sezoni je sodobna, tesna stavba takrat, ko je netesna na zgornjem delu ovoja, v podtlaku in vzgonsko črpa radon iz zemljine pod stavbo (slika 5). Izven kurilne sezone, ko je praviloma odprtih več oken, je vzgonski učinek črpanja radona manjši. (slika 4)
