Abstract

UDC: 550.34(497.4)

Earthquake Threat to Municipalities and Settlements in Slovenia

Since January 1, 1995, Slovenia has had 147 municipalities and almost 6,000 settlements. Using the Geographical Information System, we combined a layer with seismic zones, a layer with municipal borders, and a layer with centroids (coordinates) of settlements. For every municipality and settlement in Slovenia we first determined a partial assessment of the earthquake threat to municipalities relative to surfaces and population, a partial assessment of the earthquake threat to settlements relative to population, relative to the threat to the active population, that is, to the number of work places, and relative to the age of housing. We then obtained an aggregate assessment of the earthquake threat to settlements relative to population and the age of housing.

Izvleček

UDK: 550.34(497.4)

Potresna ogroženost občin in naselij v Sloveniji

V Sloveniji imamo od 1. 1. 1995 147 občin in skoraj 6000 naselij. S pomočjo geografskega informacijskega sistema smo povezali sloj s seizmičnimi območji, sloj z mejami občin in sloj s centroidi (koordinatami) naselij ter za vsako občino in naselje v Sloveniji najprej določili delno oceno potresne ogroženosti občin glede na površine in število prebivalcev, delno oceno potresne ogroženosti naselij glede na število prebivalcev, glede na ogroženost aktivnega prebivalstva oziroma število delovnih mest in glede na starost stanovanj, nato pa še skupno oceno potresne ogroženosti naselij glede na število prebivalcev in starost stanovanj.

1. Introduction

Slovenia is a country of great regional diversity because it is located at the junction of four major European geographical units: the Alps, the Dinaric Alps, the Pannonian Basin, and the Mediterranean. We therefore find a great diversity of natural phenomena and consequently numerous natural disasters.

Natural disasters are a common geographical phenomena and are a result of intertwined natural and human activities. It is common to natural disasters that they are exceptional phenomena that cause damage. If there is no damage, we can only speak of more or less interesting natural phenomena. A variety of institutions in Slovenia are involved in the study of natural disasters. The Geographical Institute of the Scientific Research Center of the Slovene Academy of Science and Art has the longest and richest tradition, and for several years the Department for Natural Disasters has operated under its auspices.

The damage caused annually in Slovenia by natural disasters varies from year to year. Due to the consequences of an earthquake in the Soča region (Geipel 1982) and other natural disasters, damage in 1976 rose to more than six percent of Slovenia's GDP for that year (Ahčan 1988). In individual parts of Slovenia this figure is often exceeded several times over. It is characteristic of Slovenia that the number of victims of natural disasters is small while the material damage is great, and with the growth of its economic power this type of damage is further increasing. With a per capita income of 10,000 USD, Slovenia ranks today among the richest countries (43rd in the world in 1995).

In recent decades, there have been no natural disasters of world proportions in Slovenia; the greatest number of victims have been claimed by avalanches. Over the long term, however, the most lives were taken and the greatest damage caused on Slovene ethnic territory and its margins by earthquakes: in 1348 there were about 500 victims in the Villach earthquake; in 1511, an earthquake destroyed many castles; the Ljubljana earthquake of 1895 damaged Ljubljana considerably (Lapajne, Tomaževič, 1991); and as a result of the 1976 Friuli earthquake, more than a thousand people lost their lives. Slovenia lies in an area of tectonically active alpidic territory where in the most threatened regions we can expect earthquakes of up to 9° on the MCS scale, and locally even stronger ones (Orožen Adamič, Sheppard, Tomaževič 1988; Orožen Adamič, 1995).

An important part of preventing earthquake damage is the assessment of earthquake threat carried out in the framework of the *Earthquake Threat and Safety from Earthquakes* research project financed by Slovenia's Ministry of Science and Technology and Ministry of Defense. This article is a summary of some of the work of this project.

To determine an estimate of the earthquake threat to settlements and population, a Geographical Information System with four basic layers has been established for the whole of Slovenia. The foundation layer of the Geographical Information System is a 100×100 meter digital relief model (Republiška ... 1989) which makes possible the locating of all natural phenomena and processes in the environment relative to latitude and longitude, that is, the Gauss-Krüger coordinate system that has been standard in Slovenia for some time (Banovec 1975; Perko 1991), and height above sea level. As to content, the most significant layer is the second, containing data from the seismological map for five hundred year return periods elaborated through the digitalization of seismic zones from the 1987 1 : 1,000,000 scale Seismological Map of the Federal Republic of Yugoslavia (Office of Seismology of Yugoslavia, Ribarić 1987). This map is also the basis for currently applied building regulations and construction technology practices (Pravilnik..., 1964, 1981, 1982). The National Geophysics Administration of the Republic of Slovenia is preparing a new map, but as it is not completely finished it is not yet a component part of the corresponding legislation.

The third layer was created using the register of municipal territorial units of the Geodetic Office of the Republic of Slovenia (1995) which also contains the digitalized borders of the new Slovene municipalities that were the basis for calculations related to the municipalities. This vectored layer was also rastered at the density of dots of the 100×100 meter digital relief model in the same manner as with the seismic zones to one hectare precision

Using the coordinates of settlements shown on the final (Republiška ... 1991), fourth basic layer of our Geographical Information System, we combined the first three layers with the extensive data base from the last census of population and housing according to settlements (Popisi ... 1961, 1991). By overlapping the individual layers and using various techniques (Rase 1988) offered by the Geographical Information System, we first analyzed the position of each settlement in Slovenia relative to seismic zones and then determined an assessment of the earthquake threat for settlements and municipalities relative to various elements. We also provided an aggregate assessment of the threat to settlements relative to two most important indicators: the location of a settlement in a specific seismic zone and the age of the housing in the settlement.

Finally, we created synthesized layers of our Geographical Information System in which we considered many indicators simultaneously and linked the Geographical Information System directly to thematic cartography in order to illustrate this article with thematic maps on which all the settlements are shown. The surface area of a settlement (the size of its square) indicates its population during the 1991 census, while the colour of the settlement (square) indicates a 12 degree assessment of the earthquake threat for each settlement relative to the position of the settlement in a seismic zone and to the predominant age of the housing. For better orientation, we added the borders of individual seismic zones as well as the borders of the municipalities.

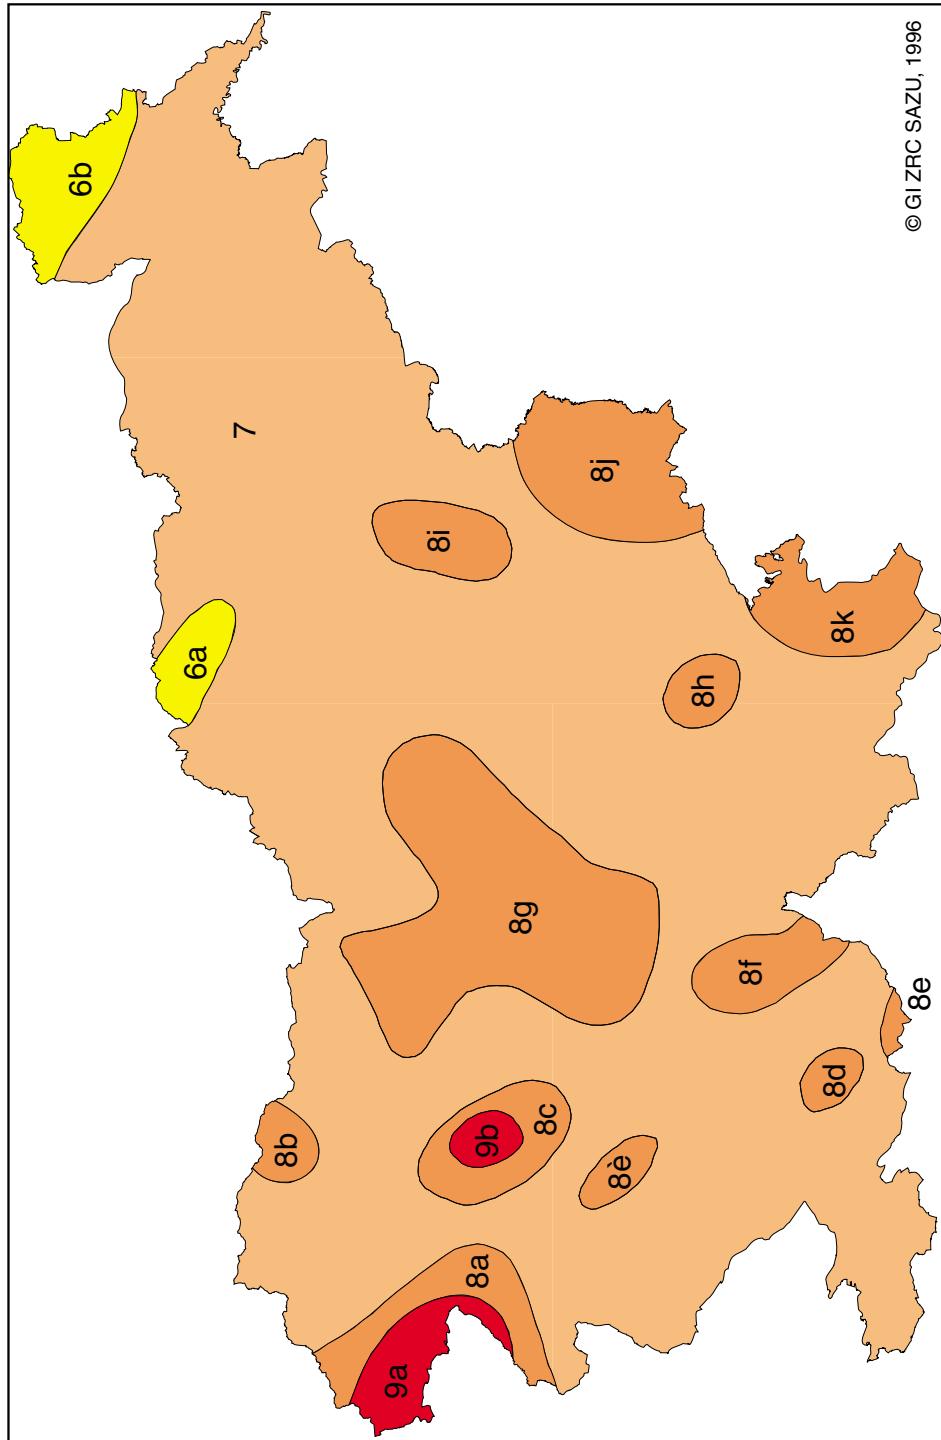

2. Seismic Zones

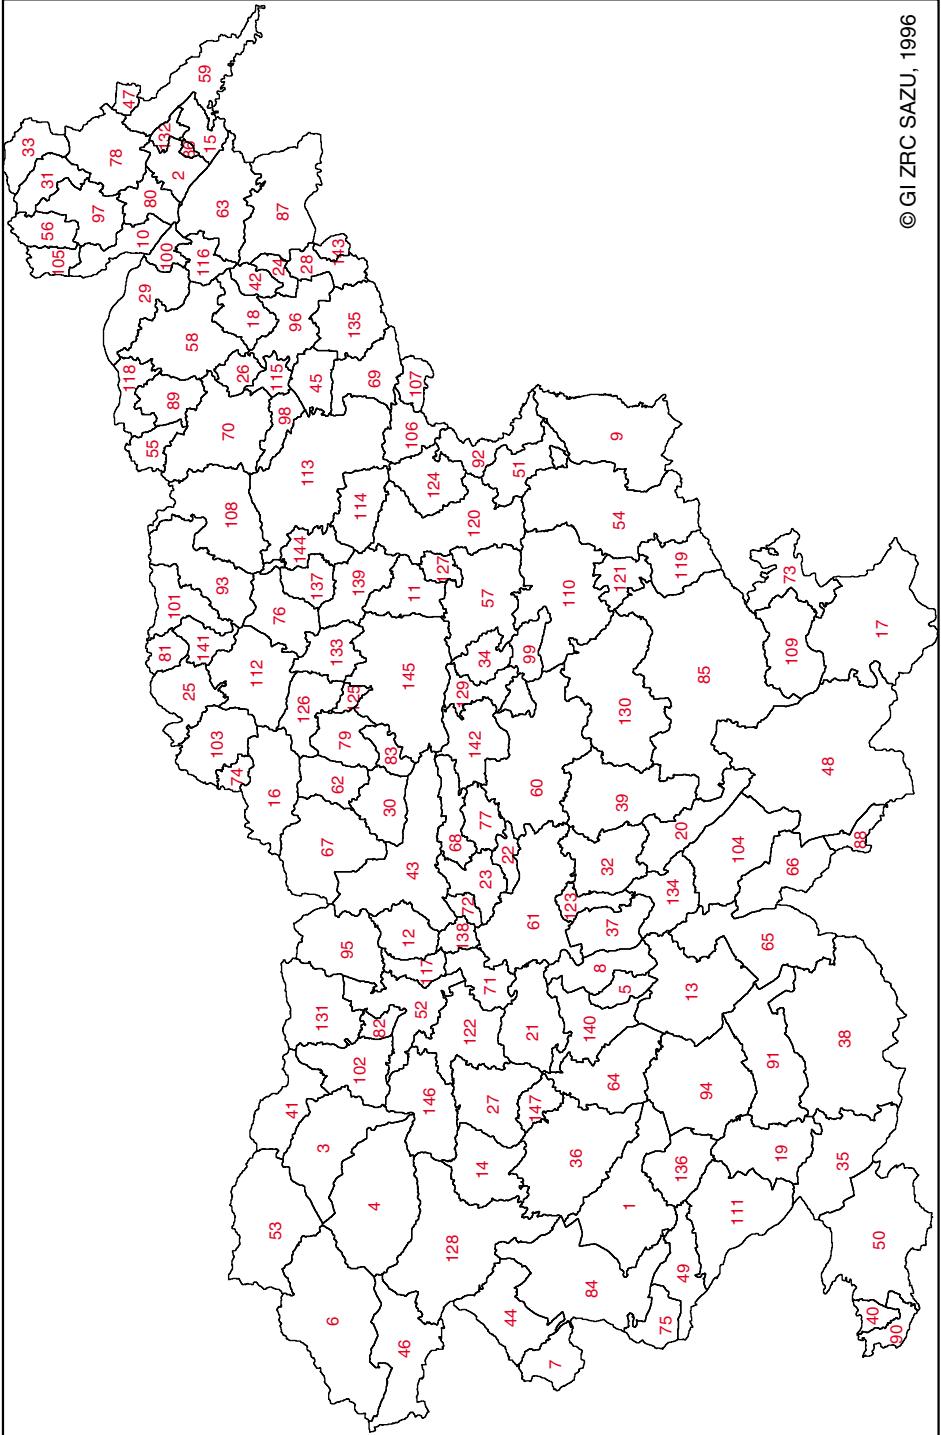

According to the 1987 seismic map for five hundred year return periods, Slovenia has seventeen seismic zones ranging from 6° to 9° on the MCS scale. Two zones are in the highest 9° MCS range, twelve zones are in the 8° range, there is only one zone in the 7° range, and two zones are in the 6° range (Orožen Adamič 1984, 1985).

Zone 9 a covers the well known earthquake region of the Upper Soča Valley that was severely affected during the 1976 earthquakes. We can call it simply the "Upper Soča Earthquake Zone." This zone stretches from Slovenia across the border with Italy into Friuli-Venezia Giulia, Resia, and the margin of the Po lowlands where the earthquake epicenters were located in 1976. In Slovenia this region covers the Soča Valley from Trnovo through Kobarid and Tolmin to Most na Soči. Here also belongs the watershed of the Nadiža River with Breginjski kot, the area most affected in Slovenia in 1976. This is the area of the former Municipality of Tolmin, the largest in Slovenia at the time, which today is divided into four municipalities: Kobarid, Bovec, Tolmin, and Kanal. In total, this largest zone of 9° MCS extends over 27,126 ha. or 1.3% of the surface of Slovenia. During the 1991 census only 6,399 people or 0.3% of Slovenia's population lived here.

Zone 9 b is the second 9° MCS zone and is traditionally called the “Idrija Earthquake Zone.” This was the former Municipality of Idrija that is now covered by the municipalities of Cerkno, Gorenja vas-Poljane, and partly by Železniki. Its surface area is 9,206 hectares or 0.5% of the surface of Slovenia; according to the 1991 census, only 4,174 people or 0.2% of the population of Slovenia live here.

Altogether there are seven municipalities that have surface areas in the 9° MCS zones, a fact clearly evident in Table 5. During the 1976 earthquake there were effects between 8° and 9° MCS here. The two 9° MCS zones together measure 36,332 hectares or 1.8% of the surface of Slovenia and in 1991 had a population of 10,573 or 0.5% of the population of Slovenia.

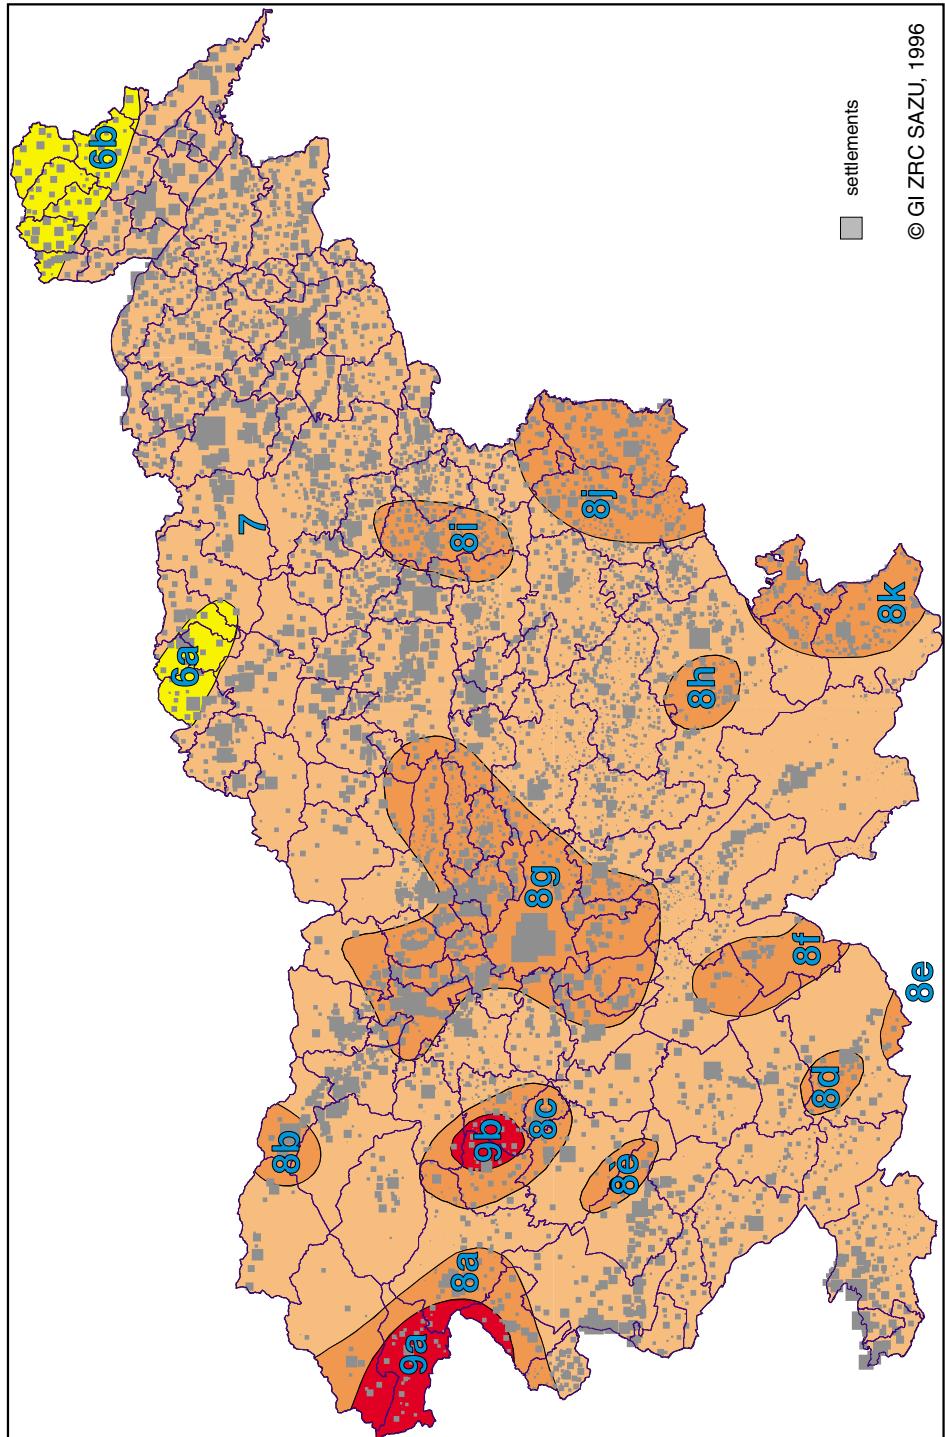

There are twelve 8° MCS earthquake zones in Slovenia. Altogether they cover 433,292 ha. or 21.4% of the surface, and 640,213 people or 32.6%, about a third, of the population of Slovenia live in them. Earthquake zone 8 a surrounds the 9° MCS Upper Soča Earthquake Zone. It covers the municipalities of Bovec, Kobarid, Kanal, and Brda and touches the Municipality of Nova Gorica. In total it covers 35,029 ha. or 1.7% of the surface of Slovenia and has 17,286 people or 0.9% of the population of Slovenia.

Earthquake zone 8 b could be called the “Jesenice Earthquake Zone” because it covers part of the Municipality of Jesenice, the less settled northern part of the Municipality of Bled, and the extreme eastern part of the Municipality of Kranjska Gora. Its surface is 11,593 ha. or 0.6% of Slovenia. Its northern part leans against the Karavanke Mountains and reaches across the border into Austria. In 1991, 21,867 people or 1.1% of the population of Slovenia lived here.

Earthquake zone 8 c is similar to zone 8 a, as it surrounds the 9° MCS Idrija Earthquake Zone (9 b). It is almost one third smaller, however, covering an area of 29,037 ha. or 1.4% of the area of Slovenia.

Figure 3: Seismological map of Slovenia for the 500 year return period with seismic zones whose numbering denotes the highest expected MCS degree, with municipality borders (M 1 : 1,300,000).

Slika 3: Seizmološka karta Slovenije za povratno periodo 500 let s seizmičnimi območji, v katerih številka označuje največjo pričakovano MCS stopnjo, in z občinskimi mejami (M 1 : 1,300,000).

It reaches to the municipalities of Tolmin, Železniki, Gorenja vas-Poljane, Žiri, Idrija, and Cerkno. In 1991, 13,785 people or 0.7% of the population lived here.

There is no doubt that zones 9 a, 9 b, 8 a, and 8 c jointly comprise the most earthquake threatened parts of the territory of Slovenia.

Earthquake zone 8 ē is in Trnovski gozd on the highest karst plateau along the border of the municipalities of Idrija and Ajdovščina. Relative to its surface area and number of residents, it belongs among the smaller earthquake zones since it measures 9,839 ha. or 0.5% of the surface of Slovenia and has 1,441 people or barely 0.1% of the population of Slovenia.

Earthquake zone 8 d is known as the “Ilirska Bistrica Earthquake Zone” and has had numerous earthquakes that so far have not been extremely destructive. The greater part of this earthquake zone lies in the Municipality of Ilirska Bistrica, and to the north it also reaches into the Municipality of Pivka. It covers 8,647 ha. or 0.4% of the surface of Slovenia and has 7,922 people or 0.4% of the population of Slovenia.

Earthquake zone 8 e is the smallest of the 8° MCS earthquake zones. It lies in the Municipality of Ilirska Bistrica on the border with Croatia. It has an area of 3,300 ha. which represents only 0.2% of the surface of Slovenia. It has just 806 people, the smallest number of all seventeen earthquake zones. Earthquake zone 8 f stretches across the municipalities of Loška dolina, Cerknica, and parts of Pivka and Ilirska Bistrica. It is characteristic of this zone that there are high Dinaric karst plateaus here with numerous karst phenomena. It measures 26,682 ha. or 1.3% of Slovenia, and it had 5,245 people or 0.3% of the population of Slovenia.

Earthquake zone 8 g is the largest 8° MCS earthquake zone and could simply be called the “Ljubljana Earthquake Zone” since it covers the greater part of the Ljubljana Basin, the whole of the Ljubljana Barje moor with its margins, the eastern part of the Sava River highlands, and the foothills of the Kamniško-Savinjske Alps. It is characterized by great geographical diversity and interweaving of landscape characteristics; in short, it is the junction between the southern Dinaric mountain system and the northern alpine environment. This is Slovenia's central area with a great concentration of population and various functions vital for the country. It covers some 169,222 ha. or 8.3% of the surface of Slovenia, and it had 463,495 people or some 23.6% of the population of Slovenia, that is, almost a quarter. More or less in the center of this zone is Ljubljana, for which a detailed microseismic regionalization has been elaborated that for a large part of the city's surface area predicts a 9° MCS earthquake according to the 500 year return period. This is shown in detail in figures 7 and it is not the subject of detailed study in the framework of this article. However, at this point and in this case specifically, it is worth noting the importance of internally structuring individual seismic zones, the basic aim of more detailed seismic or microseismic regionalization.

Earthquake zone 8 h is known as the “Dolenjske Toplice Earthquake Zone” and is almost completely within the Municipality of Novo mesto with only its very northern part reaching into the Municipality of Trebnje. Numerous faults run across this zone, and it is also known for other interesting tectonic phenomena. It covers 13,077 ha. or 0.7% of the surface of Slovenia. Together with the southern 8° MCS 8 k zone it has the characteristics of the earthquake activity along the western edge of the Dinaric mountain system.

Earthquake zone 8 i is known as the “Kozjansko Earthquake Zone.” Its central part stretches across the Municipality of Šentjur pri Celju; it reaches into the municipalities of Šmarje pri Jelšah, Laško, and Štore and touches the municipalities of Celje, Vojnik, and Slovenske Konjice. It covers 25,913 ha. or 1.3% of the surface of Slovenia and has 21,523 people or 1.1% of the population of Slovenia.

For earthquake zone 8 j, the name “Krško-Brežice Earthquake Zone” has become recognized. After the Ljubljana Earthquake Zone (8 g), this is the second largest 8° MCS earthquake zone. It covers 61,587 ha. or 3.0% of the surface of Slovenia, and it had 53,677 people or 2.7% of the population of Slovenia. This zone borders on neighbouring Croatia and covers the Municipality of Brežice completely and partially the municipalities of Krško, Kozje, and Podčetrtek.

Figure 7: MCS areas and density of population per ha in Ljubljana.
Slika 7: MCS območja in gostota poselitve v Ljubljani.

Earthquake zone 8 k is called the "Bela krajina Earthquake Zone." It stretches across part of the municipalities of Semič, Metlika, and Črnomelj. Across the Kolpa River it reaches into neighbouring Croatia. It is known for relatively frequent but not very destructive earthquake activity. It covers 39,303 ha. or 1.9% of the surface of Slovenia, and it had 25,216 people or 1.3% of the population of Slovenia. There is only one undivided 7° MCS earthquake zone that stretches practically across the whole of Slovenia. It covers 1,502,247 ha. or 74.1%, that is, almost three quarters of the territory of Slovenia where in 1991 1,284,614 people or 65.3% of the population of Slovenia lived, almost two thirds of the total Slovene population.

In earthquake zone 6 a only earthquake effects to 6° MCS can be expected. We can call it the "Dravograd Earthquake Zone." It covers parts of the municipalities of Dravograd, Muta, Vuženica, Radlje ob Dravi, and Podvelka-Ribnica. It measures 18,299 ha. or 0.9% of the surface of Slovenia and had 13,108 people or 0.7% of the population of Slovenia.

Earthquake zone 6 b is the 6° MCS "Prekmurje Earthquake Zone" which contains the whole of the Goričko region with the municipalities of Hodoš-Šalovci/Hodos-Šalovci and Gornji Petrovci and parts of the municipalities of Kuzma, Rogaševci, Puconci, Moravske Toplice, and Kobilje. Its surface area is 37,020 ha. or 1.8% of the surface of Slovenia. In 1991 it had 17,514 people or 0.9% of the population of Slovenia.

The last two earthquake zones, 6 a and 6 b, are the least threatened earthquake zones where we do not expect major earthquake effects and together cover 55,319 ha. or only 2.7% of the surface of Slovenia. In 1991, 30,622 people or 1.6% of the population of Slovenia lived here.

3. Assessment of Earthquake Threat to Municipalities in Slovenia

By combining the layer of seismic zones with the layer of municipalities in the Geographical Information System, we determined an assessment of the earthquake threat to all the municipalities in Slovenia. Because the surface areas of the municipalities in the Geographical Information System are rastered to a 100 × 100 meter or one hectare degree of accuracy, in some cases there are minor deviations from the actual surface areas of the municipalities.

Calculations of surface areas and proportions of surface areas of the municipalities are given according to individual MCS zones in Table 2 in alphabetical order, and in Table 3 the municipalities are sorted according to their proportion of surface areas of specific MCS degrees. In first place are municipalities with the largest proportion of surface area in earthquake zones with the highest level of earthquake threat while in last place are municipalities with the largest proportion of surface area in earthquake zones with the lowest level of earthquake threat.

From this perspective, the Municipality of Kobarid has the highest level of earthquake threat, having more than four fifths of its territory in a 9° MCS earthquake zone. It is followed by the municipalities of Cerkno, Gorenja vas-Poljane, Kanal, Bovec, Tolmin, and Železniki. Thus only seven municipalities or 5% of all the municipalities in Slovenia have part of their territory in a 9° MCS earthquake zone.

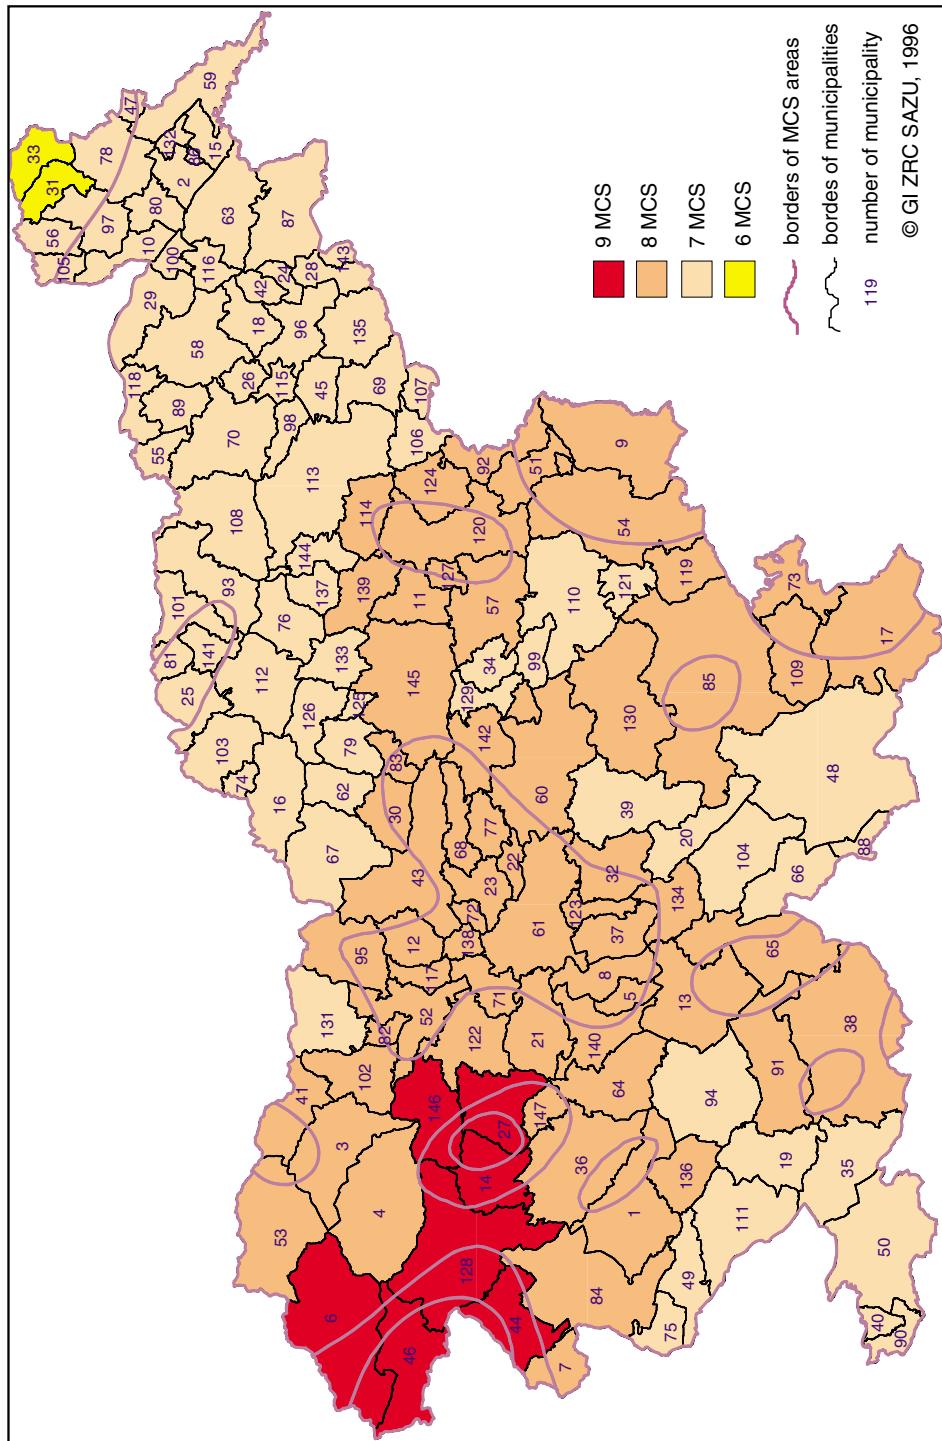

If we consider 8° and 9° MCS earthquake zones together, the most threatened municipalities are Brežice, Dol pri Ljubljani, Domžale, Ig, Lukovica, Mengš, Metlika, Moravče, Šenčur, Škofljica, and Vodice since they have their entire territories in 8° MCS earthquake zones.

The municipalities of Gornji Petrovci and Hodoš-Šalovci have the lowest level of earthquake threat since they are totally within 6° MCS earthquake zones.

To determine the mean or average earthquake threat to the surface of municipalities, we calculated a coefficient of earthquake threat to surfaces, giving a weight of 3 to 9° MCS earthquake zones, of 2 to 8° MCS earthquake zones, of 1 to the 7° MCS earthquake zone, and of 0 to 6° MCS earthquake

Figure 8: Highest expected degree MCS by municipalities for the 500 year return period (M 1 : 1,300,000).

Slika 8: Največja pričakovana MCS stopnja po občinah za 500 letno povratno periodo (M 1 : 1,300,000).

zones. We divided the sums by the total surface area of the municipalities and divided the resulting coefficient again, this time with the largest possible coefficient so that the final values of the coefficients of earthquake threat to the surface areas were distributed between 0 and 1. Thus municipalities with their total territory in a 9° MCS zone have a coefficient of earthquake threat of 1, municipalities with their total surface area in a 6° MCS zone have a coefficient of earthquake threat of 0, and the remaining have coefficient values in between.

The municipality of Kobarid has the highest coefficient of earthquake threat to its surface area (0.9307), followed by the municipalities of Cerkno (0.7096) and Kanal (0.6789). The coefficient of earthquake threat for the whole of Slovenia amounts to 0.4074. Only forty-six municipalities have a higher coefficient of earthquake threat, while 101 have lower coefficients. The municipalities of Gornji Petrovci and Hodoš-Šalovci have the lowest coefficient, both 0.0000.

Similar to the determination of the mean or average earthquake threat to the surface areas of municipalities, we also calculated the coefficient of earthquake threat to population, giving a weight of 3 to the population in 9° MCS earthquake zones, of 2 in 8° MCS earthquake zones, of 1 in the 7° MCS earthquake zone, and of 0 in 6° MCS earthquake zones. We divided the sums by the total population of the municipalities and divided the resulting coefficient again, this time with the highest possible coefficient so that the final values of the coefficients of earthquake threat to the population were distributed between 0 and 1. Thus municipalities with their total territory in a 9° MCS zone have a coefficient of earthquake threat to the population of 1, municipalities with their total surface area in a 6° MCS zone have a coefficient of earthquake threat to the population of 0, and the remaining have coefficient values in between.

The Municipality of Kobarid has the highest coefficient of earthquake threat to the population (1.0000) since its entire population lives in the 9° MCS earthquake zone, followed by the municipalities of Cerkno (0.8289), Kanal (0.6853), and Bovec (0.6810). The coefficient of earthquake threat to the population of Slovenia is 0.4403. Only forty-one municipalities have a higher coefficient of earthquake threat to population while 106 municipalities have lower coefficients. The municipalities of Gornji Petrovci, Hodoš-Šalovci, Kobilje, and Vuzenica have the lowest coefficient of earthquake threat to population, all 0.0000. The coefficient applies to the population of municipalities according to the census of 1991.

Municipalities where the coefficient of earthquake threat to population is higher than the coefficient of earthquake threat to surface areas have a higher density of population in areas with higher MCS degrees than in areas with lower MCS degrees, which from the viewpoint of earthquake threat is an inappropriate distribution of population. The coefficient of earthquake threat to surface areas and the coefficient of earthquake threat to population are relative indicators of earthquake threat since they illustrate relative comparisons between municipalities. Thus one municipality may have higher coefficients than another although in the absolute sense more surface area in the second lies in a 9° MCS zone, or in the absolute sense more people live in the 9° MCS zone in the second municipality than in the first.

TABLE 2: SURFACE AREAS AND PROPORTIONS OF MUNICIPALITIES IN SLOVENIA ACCORDING TO MCS ZONES (MUNICIPALITIES ARE LISTED IN ALPHABETICAL ORDER).

PREGLEDNICA 2: POVRŠINE IN DELEŽI OBČIN SLOVENIJE PO MCS OBMOČJIH (OBČINE SO RAZVRŠČENE PO ABECEDNEM VRSTNEM REDU).

4. Assessment of Earthquake Threat by settlements

Using the Geographical Information System we combined the layer of seismic zones with the layer of centroids (coordinates) of settlements (Republiška ... 1991) and for every settlement in Slovenia first determined partial assessments of earthquake threat relative to the population, relative to the

threat to the active population, that is, the number of work places, and relative to the age of housing. Then we calculated the mean assessment of earthquake threat to settlements relative to population and age of housing (Popisi ... 1961, 1991).

The source of data on the number and age of housing is the 1991 census of population and housing which offers two synthetic indicators.

The first shows the proportion (%) of individual types of housing in a settlement, informing us of the structural characteristics of individual settlements. It is significant whether we are dealing with a majority of individual and more or less scattered houses or with multistory buildings in which the concentration of population is substantially higher and therefore offers the possibility of a much larger number of victims. While naturally we must not generalize this information uncritically, according to experience, however, the difference in the concentration of population between individual housing and apartment buildings is approximately in the ratio of one to three.

The second synthetic indicator shows the dominant age of the housing in individual settlements (Ravbar 1995). The following six types of settlements in Slovenia relative to the dominant age of housing are shown with letters on figure 10:

- A distinct domination of housing built before 1945 (above 50%),
- B distinct domination of housing built between 1945 and 1970 (above 50%),
- C distinct domination of housing built after 1970 (above 50%),
- a moderate domination of housing built before 1945,
- b moderate domination of housing built between 1945 and 1970,
- c moderate domination of housing built after 1970.

“Distinct domination” means that more than 50% of all the housing was built in a certain period (absolute domination), while “moderate domination” means that while less than half of the housing was built in a certain period it is more than in either of the other two periods (relative dominance). It generally applies that the older the housing is, the worse its quality and the lower the safety of its anti-earthquake technical construction. The greater the proportion of new housing in the settlement is, particularly that built after 1970 when earthquake proof construction received more attention, the less the threat to the settlement.

According to the dominant age of their housing, settlements may be divided into three basic types:

- settlements with absolute and relative domination of housing built after 1970,
- settlements with absolute and relative domination of housing built between 1945 and 1970,
- settlements with absolute and relative domination of housing built before 1945.

Here we are assuming that the settlements more threatened by earthquake are those which are dominated by older housing and vice versa (Tomažević 1987). Modern anti-earthquake construction came into use to a greater extent following the 1963 Skopje earthquake (Tomažević, Sheppard 1982). We divided the fifty-year period following World War II into two equal twenty-five year periods. Simplified, the first period is that before the increasing use of anti-earthquake construction, while the second is the modern period. Of course, we also considered older buildings as well, which we combined as housing built before the end of World War II.

On the other hand, we combined settlements according to their location in seismic zones into four basic types:

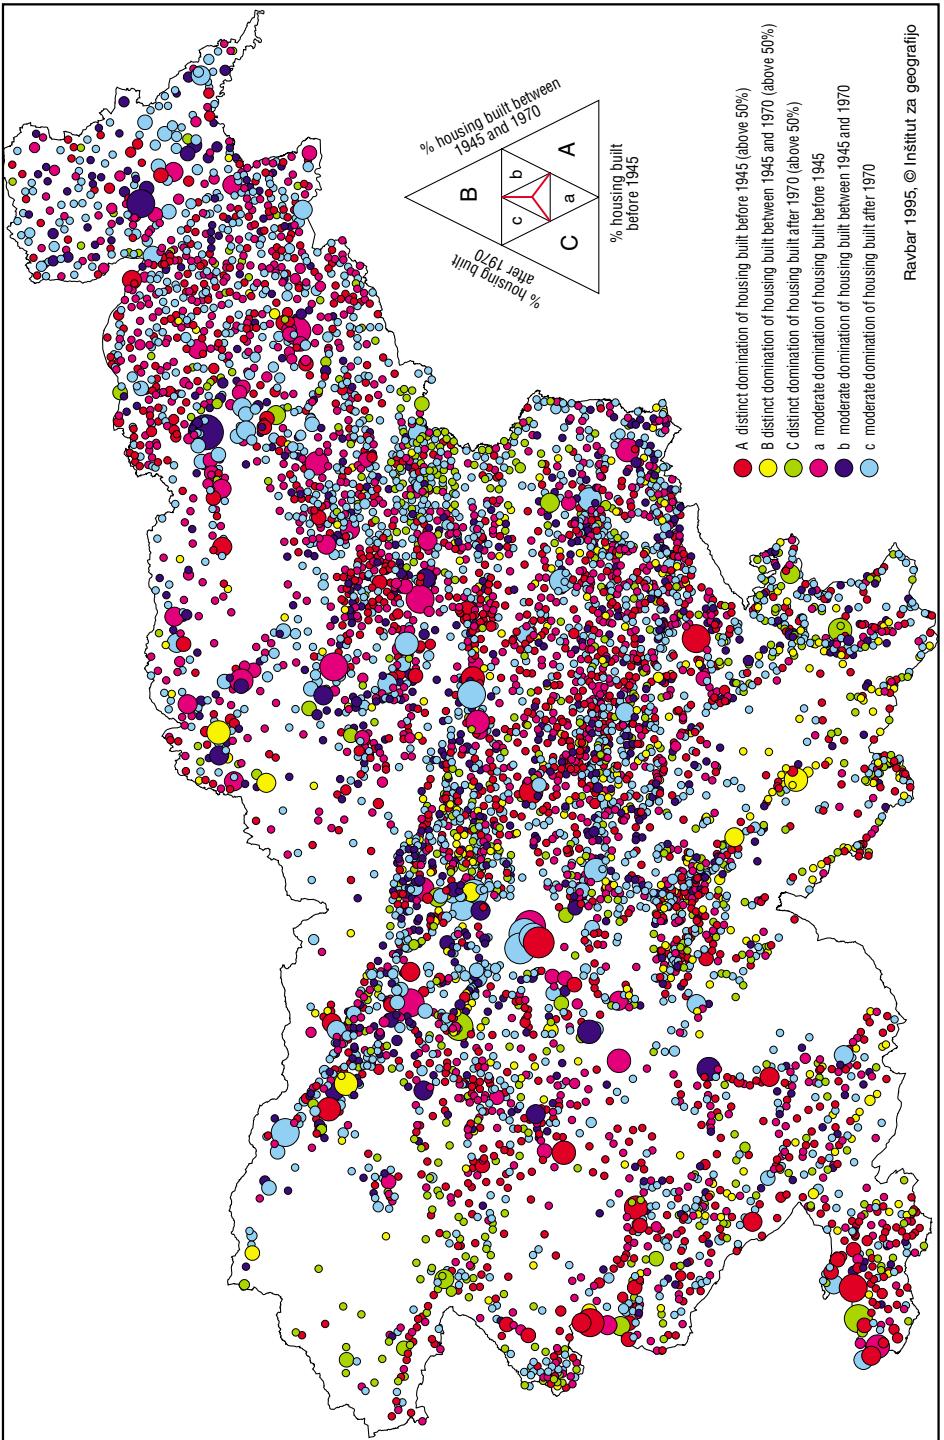

- settlements located in 6° MCS zones,
- settlements located in the 7° MCS zone,
- settlements located in 8° MCS zones,
- settlements located in 9° MCS zones.

For every settlement we combined the types relative to age of housing and to location in seismic zones and got twelve combinations or categories that we sorted from lowest to highest earthquake threat as follows:

- category 1 in 6° MCS zones dominated by housing built after 1970,
- category 2 in 6° MCS zones dominated by housing built between 1945 and 1970,

Figure 9: Highest expected degree MCS by settlements for the 500 year return period (M 1:1,300,000).

Slika 9: Najveća pričakovana MCS stopnja po naseljih za 500 letno povratno periodo (M 1:1,300,000).

- category 3 in 6° MCS zones dominated by housing built before 1945,
- category 4 in 7° MCS zone dominated by housing built after 1970,
- category 5 in 7° MCS zone dominated by housing built between 1945 and 1970,
- category 6 in 7° MCS zone dominated by housing built before 1945,
- category 7 in 8° MCS zones dominated by housing built after 1970,
- category 8 in 8° MCS zones dominated by housing built between 1945 and 1970,
- category 9 in 8° MCS zones dominated by housing built before 1945,
- category 10 in 9° MCS zones dominated by housing built after 1970,
- category 11 in 9° MCS zones dominated by housing built between 1945 and 1970,
- category 12 in 9° MCS zones dominated by housing built before 1945.

This means that the MCS degree is considered in first place and within this, the age of the housing.

TABLE 7: SURVEY OF THE NUMBER AND PROPORTION OF SETTLEMENTS AND NUMBER AND PROPORTION OF POPULATION BY DEGREE OF EARTHQUAKE THREAT TO SETTLEMENTS.

PREGLEDNICA 7: PREGLED ŠTEVILA IN DELEŽA NASELIJ TER ŠTEVILA IN DELEŽA PREBIVALCEV PO STOPNJAH POTRESNE OGROŽENOSTI NASELIJ.

Synthetic type	Number of settlements	Proportions of number of settlements in %	Population in 1991	Proportion of population in 1991 in %
12	41	0.69	6883	0.35
11	4	0.07	142	0.01
10	22	0.37	3548	0.18

2	22	0.37	6679	0.34
1	39	0.66	10609	0.54
Total	5918	100.00	1965983	100.00

The number of settlements is relatively normally distributed according to the degree of earthquake threat, and in even larger measure this also applies to the distribution of the population of the settlements.

In Slovenia there are forty-one settlements in the 12th degree earthquake threat category in which 6,883 people lived in 1991, that is, barely one third of the total population of Slovenia lives in settlements in 9° MCS zones in housing built mostly before 1945.

It is similar at the other extreme since there are only thirty-nine settlements in the 1st degree earthquake threat category in which 10,609 people lived in 1991. This means that only 0.5% of the total population of Slovenia lived in settlements in 6° MCS zones in housing built mostly after 1970.

The greatest number of settlements are in the 6th category, that is, in the 7° MCS zone dominated by housing built before 1945. In these settlements, a third of all Slovene settlements, 622,551 people lived in 1991, that is, almost one third of the total population of Slovenia in that year.

The number of settlements stands out in the 4th category where the settlements are located in the 7° MCS zone with housing built mainly after 1970. In these settlements, which represent more than 25% of all settlements in Slovenia, 370,958 people lived during the 1991 census, a little less than one fifth of the total population of Slovenia.

Figure 10: Pattern of settlements and age of housing by settlement in Slovenia (M 1:1,300,000; Ravbar 1995, cartography Sajko Institute for Geography).

Slika 10: Starost stanovanjskih objektov po naseljih v Republiki Sloveniji (M 1:1,300,000; Ravbar 1995, kartografija Sajko Inštitut za Geografijo).

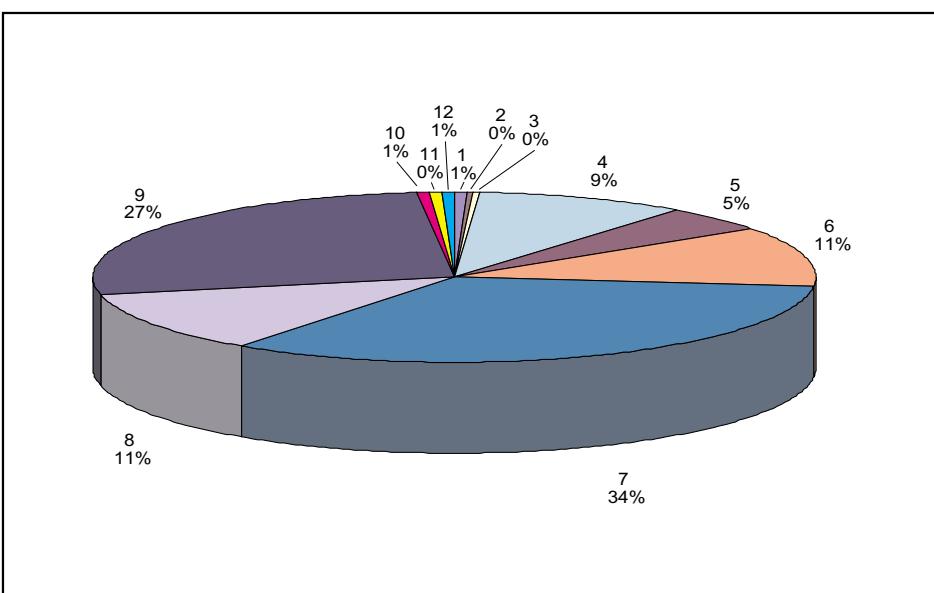

Figure 12: Proportion of population in Slovenia in 1991 by degree of earthquake threat to settlements.

Slika 12: Deleži števila prebivalcev Slovenije leta 1991 po stopnjah potresne ogroženosti naselij.

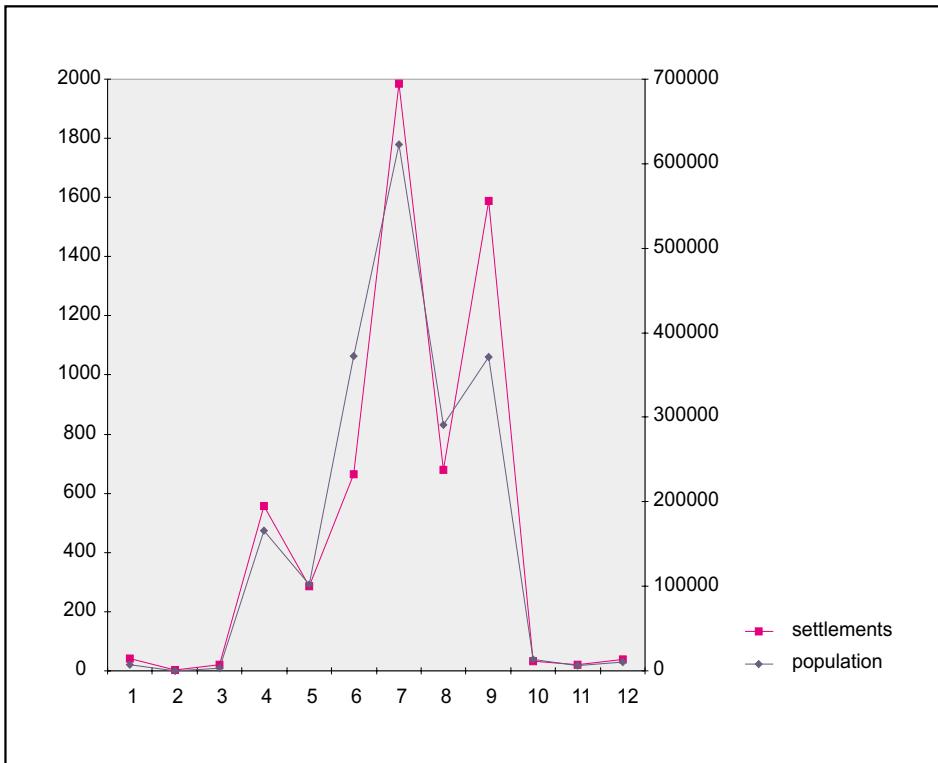

Figure 13: Comparison of number of settlements and population by degree of earthquake threat to settlements in Slovenia in 1991.
Slika 13: Primerjava števila naselij in števila prebivalcev po stopnjah potresne ogroženosti naselij v Sloveniji leta 1991.

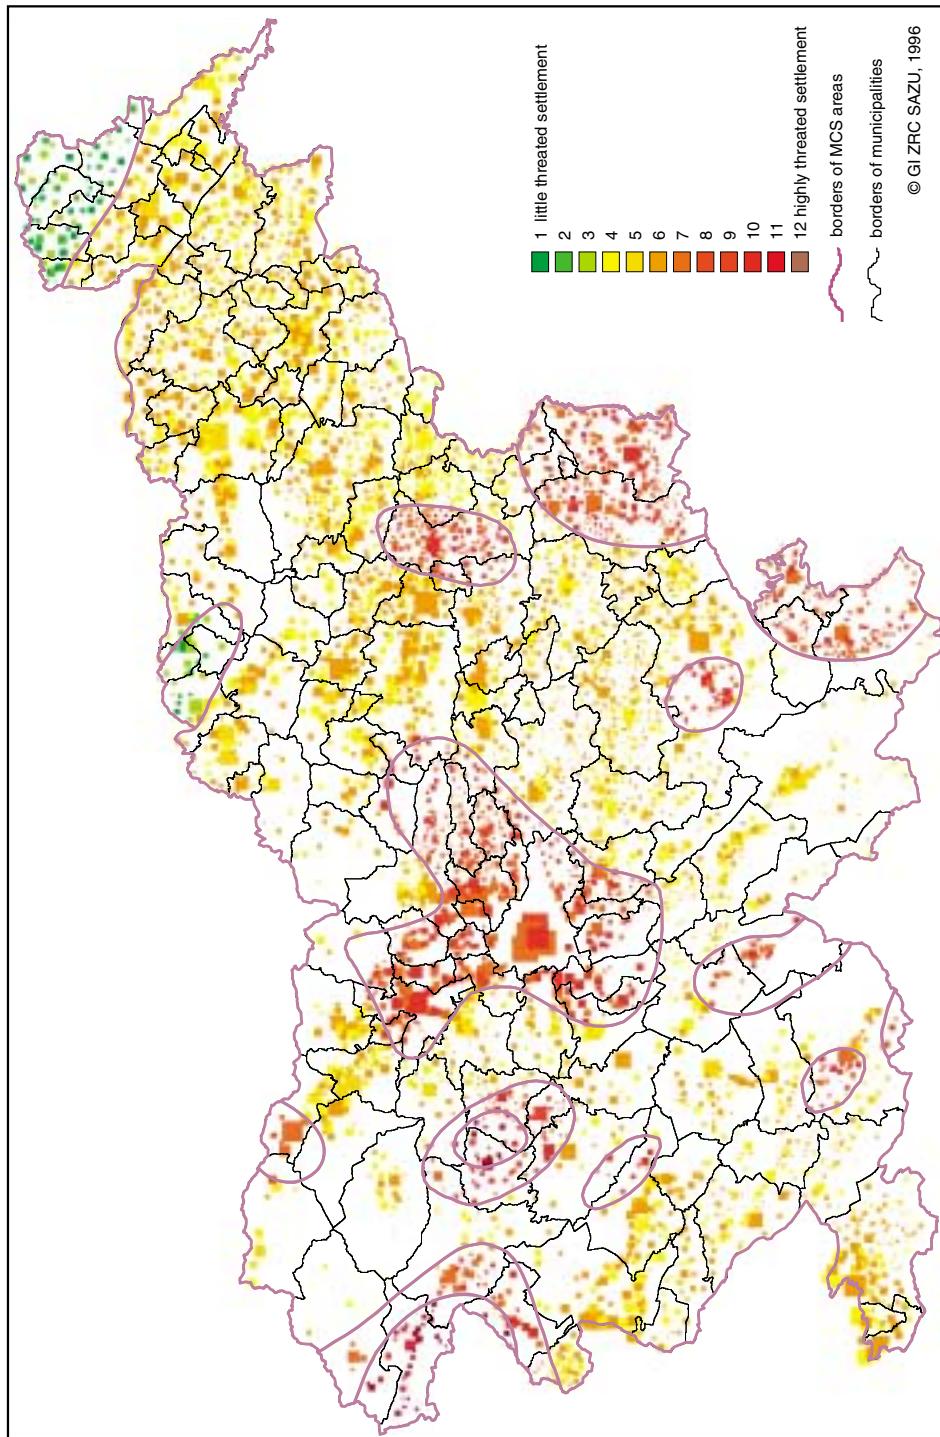

The largest average size of settlements is found in the 7th category, some 560 people, where the settlements are in 8° MCS zones dominated by housing built after 1970. It is followed by the 5th category, 429 people per settlement, where the settlements are in the 7° MCS zone dominated by housing built between 1945 and 1970.

Only in the 11th and 12th categories is the average size of settlements less than 200 people. This means that the smallest settlements are in the most threatened categories, which is understandable since these are settlements with falling populations, badly aging structure, and old housing.

5. Conclusion

On one hand, our work was oriented toward research of relatively great detail, examining and determining the earthquake threat for every Slovene settlement and each Slovene municipality; on the other hand, we were also interested in the overall earthquake threat to the whole of Slovenia.

According to the 1987 seismic map for 500 year return periods, Slovenia has less than two percent of its surface area in the 9° MCS earthquake zone. At the same time, this is a sparsely settled area since in 1991 only 0.5% of the population of Slovenia lived here and the density of population was barely twenty-nine people per square kilometer while the Slovene average in the same period was ninety-seven people per square kilometer. The number of the active population or of work places here was 4,557, some 0.5% of all work places in Slovenia. These are areas of strong depopulation trends, a factor quite distinct in the 9° MCS Upper Soča Earthquake Zone (9 a), and somewhat less distinct

in the 9° MCS Idrija Earthquake Zone (9 b). From the point of view of earthquake threat this is gratifying, but we must be aware, however, that there are still more than 10,000 people living in these areas.

There are twelve 8° MCS zones that together embrace a good fifth of Slovenia (21.27%), a third of its population (32.56%), and one third of its work places (33.78%). Together with the 9° MCS zones they cover 23.26% of the surface of Slovenia, almost one quarter of the country. In these zones major consequences from earthquakes and more human casualties can be expected. In total somewhat over 650,000 people live in these zones, mostly in the 8° MCS zones where the average density of population is 148 people per square kilometer, in some individual zones almost 300 people per square kilometer (8 g), and where there are almost 340,000 active working people. Overall, the 8° MCS zones are areas of population growth; between 1961 and 1991 their populations grew by one third, although in individual zones the population has dropped (8 c, 8 e, 8 f). If we study the 8° MCS zones in more detail, this situation appears primarily due to the intense growth of population in zone 8 g, that is, in the Ljubljana Basin. Numerous functions vital to the Slovene state are situated in this zone, which further increases the level of danger. All this supports the strategic correctness of the systematic orientation toward the polycentric development of the Republic of Slovenia that should mitigate the effects on the central functions of the state in the event of a catastrophic earthquake in zone 8 g. If this zone were struck by an earthquake equal to that of 1895, the consequences would be substantially greater. One hundred years ago, Ljubljana was a provincial city with less than 30,000 residents, while today with its suburbs and as the capital of the country it has more than 300,000 residents. Earthquake zone 8 g alone contains one quarter of the work places in Slovenia.

The 7° MCS earthquake zone covers three quarters of the surface of Slovenia. In 1991, two thirds of the population of Slovenia lived here, and the population density was eighty-six people per square kilometer, below the Slovene average. Here also were two thirds of all Slovene work places. Between 1961 and 1991 the population here increased by one fifth.

In Slovenia we have only two 6° MCS zones which together cover a little less than three percent of the country's surface area in which only a little over 1.5% of the population lives and where a little less than 1.5% of the population works. These are the only relatively earthquake safe zones in Slovenia. The National Geophysics Administration of the Republic of Slovenia is preparing a new and enhanced seismic map of Slovenia. The work has not yet been completed and, which is just as important, is therefore not yet part of the technical building regulations. When this map is completed and officially adopted as the starting point for applying technical construction measures, it will be sensible to further suitably elaborate this research.

7. Povzetek – Summary

Potresna ogroženost občin in naselij v Sloveniji

Milan Orožen Adamič

Drago Perko

Naše delo je bilo na eni strani usmerjeno v raziskovanje razmeroma velikih podrobnosti, raziskovanje in ugotavljanje potresne ogroženosti vsakega slovenskega naselja in vsake slovenske občine, na drugi strani pa nas je zanimala tudi celovita potresno ogroženost Slovenije.

Po seizmični karti iz leta 1987 za petstoletno povratno periodo je v Sloveniji manj kot 2 % površine v 9. MCS območju. Hkrati je to redko poseljeno območje, saj je v njem leta 1991 prebivalo le pol odstotka prebivalcev Slovenije, gostota prebivalstva pa je bila komaj 29 ljudi na km², slovensko povprečje pa je bilo istega leta 97 ljudi na km². Število aktivnih prebivalcev oziroma delovnih mest je bilo 4557, kar je pol odstotka vseh delovnih mest v Sloveniji. To so območja močne depopulacije, ki je bolj izrazita v Zgornjesoškem območju 9. MCS stopnje (9 a) in nekoliko manj izrazita v Idrijskem območju 9. MCS stopnje (9 b). To je z vidika potresne ogroženosti sicer razveseljivo, vendar se moramo zavedati, da na teh območjih še vedno živi več kot 10.000 ljudi.

Območij 8. MCS stopnje je 12 in skupaj obsegajo dobro petino Slovenije (21,27 %), tretjino prebivalstva Slovenije (32,56 %) in tretjino delovnih mest (33,78 %). To je skupaj z območji 9. MCS stopnje 23,26 % površine Slovenije, kar je slaba četrtina Slovenije. V teh območjih pričakujemo večje posledice potresov in tudi človeške žrtve. V celoti v teh krajih prebiva nekaj čez 650.000 prebivalcev, večina na območjih 8. MCS stopnje, kjer je povprečna gostota prebivalstva 148 ljudi na km², na po-

sameznih območjih pa skoraj 300 (8 g), dela pa skoraj 340.000 ljudi. V celoti so območja 8. MCS stopnje območja naraščanja števila prebivalcev, med letoma 1961 in 1991 je naraslo kar za tretjino, na posameznih območjih pa število prebivalcev tudi upada (8 č, 8 e, 8 f). Če nekoliko podrobnejne pogledamo območja 8. MCS stopnje, je takva situacija predvsem zaradi intenzivne rasti prebivalstva v območju 8 g oziroma v Ljubljanski kotlini. Tu so koncentrirane številne vitalne funkcije slovenske države, kar še povečuje stopnjo nevarnosti. Vse to potrjuje strateško pravilnost sistematičnega usmerjanja v policentričen razvoj Republike Slovenije in s tem zmanjševanje prizadetosti centralnih funkcij države ob katastrofalmem potresu v območju 8 g. Če bi območje prizadel enak potres kot leta 1895, bi bile posledice bistveno večje. Pred 100 leti je bila Ljubljana provincialno mesto z manj kot 30.000 prebivalci, danes pa ima z obrobjem kot prestolnica države več kot 300.000. Samo območje 8 g ima kar četrtnino delovnih mest v Sloveniji.

Območje 7. MCS stopnje obsega tri četrtine površine Slovenije. Tu sta leta 1991 prebivali dve tretjini prebivalstva Slovenije, gostota pa je bila 86 ljudi na km², torej pod slovenskim povprečjem, tu pa je bilo tudi dve tretjini vseh slovenskih delovnih mest. Število prebivalcev se je med letoma 1961 in 1991 povečalo za petino.

V Sloveniji imamo le dve območji 6. MCS stopnje, ki skupaj obsegata slabe 3 % njene površine, v njih prebiva le dober odstotek in pol prebivalstva Slovenije, dela pa slab odstotek in pol. To so edina pred potresi razmeroma varna območja Slovenije.

Uprava za geofiziko Republike Slovenije pripravlja novo izpopolnjeno seizmično karto Slovenije, ki pa še ni končana in, kar je prav tako pomembno, zato tudi ni del gradbenotehnične regulative. Ko bo ta karta izdelana in tudi uradno sprejeta kot izhodišče za uveljavljanje gradbenotehničnih ukrepov, bo smiselno to raziskavo ustrezno dopolniti.
