PRAVI TRENUTEK ZA NOV ZAČETEK

Odobrena indikacija za prehod med adjuvantnim zdravljenjem

AROMASIN®
eksemestan

BISTVENE INFORMACIJE IZ POVZETKA GLAVNIH ZNAČILNOSTI ZDRAVILA AROMASIN® 25 mg obložene tablete

Sestava in oblika zdravila: obložena tableta vsebuje 25 mg eksemestana. **Indikacije:** adjuvantno zdravljenje žensk po menopavzi, ki imajo invazivnega zgodnjega raka dojke s pozitivnimi estrogenskimi receptorji in so se uvodoma vsaj 2 leti zdravile s tamoksifenom. Zdravljenje napredovalega raka dojke pri ženskah z naravno ali umetno povzročeno menopavzo, pri katerih je bolezen napredovala po antiestrogenski terapiji. Učinkovitost še ni bila dokazana pri bolnicah, pri katerih tumorske celice nimajo estrogenskih receptorjev. **Odmerjanje in način uporabe:** 25 mg enkrat na dan, najbolje po jedi. Pri bolnicah z zgodnjim rakom dojke je treba zdravljenje nadaljevati do dopolnjene petega leta adjuvantnega hormonskega zdravljenja oz. do recidiva tumorja. Pri bolnicah z napredovalim rakom dojke je treba zdravljenje nadaljevati, dokler ni razvidno napredovanje tumorja. **Kontraindikacije:** znana preobčutljivost na učinkovino zdravila ali na katero od pomožnih snovi, ženske pred menopavzo, nosečnice in doječe matere. **Posebna opozorila in previdnostni ukrepi:** predmenopavzni endokrini status, jetrna ali ledvična okvara, bolniki z redkimi prirojenimi motnjami, kot so fruktozna intoleranca, malabsorpcija glukoze-galaktose ali insuficienca saharoze-izomaltaze. Lahko povzroči alergijske reakcije ali zmanjšanje mineralne gostote kosti. Ženskam z osteoporozo ali tveganjem zanjo je treba izrecno izmeriti gostoto kosti s kostno densitometrijo, in sicer na začetku zdravljenja in nato redno med zdravljenjem. **Medsebojno delovanje z drugimi zdravili:** sočasna uporaba zdravil - npr. rifampicina, antiepileptikov (npr. fenitoina ali karbamazepina) ali železičnih pripravkov s šentjaževko - ki inducirajo CYP 3A4, lahko zmanjša učinkovitost Aromasina. Uporabljati ga je treba previdno z zdravili, ki se presnavljajo s pomočjo CYP 3A4 in ki imajo ozek terapevtski interval. Kliničnih izkušenj s sočasno uporabo zdravila Aromasin in drugih zdravil proti raku ni. Ne sme se jemati sočasno z zdravili, ki vsebujejo estrogen, saj bi ta izničila njegovo farmakološko delovanje. **Vpliv na sposobnost vožnje in upravljanja s stroji:** po uporabi zdravila je lahko psihofizična sposobnost za upravljanje s stroji ali vožnjo avtomobila zmanjšana. **Neželeni učinki:** neželeni učinki so bili v študijah ponavadi blagi do zmerni. **Zelo pogosti (> 10 %):** vročinski oblivi, bolečine v sklepih, utrujenost, slabost, nespčnost, glavobol, močnejše znojenje, blago zvišanje alkalne fosfataze. **Način in režim izdajanja:** zdravilo se izdaja le na recept, uporablja pa se po navodilu in pod posebnim nadzorom zdravnika specialista ali od njega pooblaščenega zdravnika. **Imetnik dovoljenja za promet:** Pfizer Luxembourg SARL, 283, route d'Arlon, L-8011 Strassen, Luksemburg. **Datum zadnje revizije besedila:** 9.12.2005
Pred predpisovanjem se seznanite s celotnim povzetkom glavnih značilnosti zdravila.

research article

What is the most common mammographic appearance of T1a and T1b invasive breast cancer?

Maja Podkrajšek¹, Janez Žgajnar², Marko Hočevár²

¹Department of Radiology and ²Department of Surgical Oncology,
Institute of Oncology Ljubljana, Slovenia

Background. Data about the mammographic appearance of breast cancer smaller than 10 mm are very limited and different authors use different mammographic criteria. The aim of this study was to determine the most common mammographic appearance of small invasive breast cancers (T1a and T1b).

Patients and methods. The study group consisted of 100 women with 102 small (1-10 mm) invasive breast cancers detected on mammography at a single institution in 16 months period. The mammographic appearance of tumours was classified as: mass, mass with associated calcifications, only calcifications or others (asymmetric density and architectural distortion).

Results. The most common mammographic appearance was a mass without calcifications (60/102; 59%). Additional 12/102 (11%) tumours had a mammographic appearance of a mass with associated calcifications. Only microcalcifications were detected in 12 (11 %) and asymmetric density and architectural distortion in 18 breast cancers (18 %). Most (44/60) cancers which presented mammographically as a mass had stellate margins. The proportion of castig type calcifications was higher in women under 50 years.

Conclusions: The most common mammographic finding of small breast cancer is a mass with stellate margins independent of the age of patients. Calcifications with/without mass are more common in woman under 50 years.

Key words: breast cancer; mammographic appearance; microcalcifications, stellate; casting; asymmetric density

Introduction

Breast cancer is the most common non-cutaneous cancer in European women. In Slovenia 1020 new cases and 425 deaths from breast cancer are estimated in 2005. An average Slovenian woman has a lifetime risk of 1 in 16 for developing breast cancer.¹

Mammography can identify breast cancers too small to palpate on physical examination. Clinical trials have established that screening with mammography may decrease breast cancer mortality, because breast cancers detected on screening mammography are smaller and more likely not to have spread to regional lymph nodes as compared with breast cancers detected at physical examination.²⁻⁴ Additionally, since breast cancers detected on screening mammography are smaller, they can be more often treated with breast conservation and with less-toxic systemic therapy.⁵

Table 1. Classification of mammographic findings

1	Mass without calcifications: with stellate margins round/oval mass
2	Mass with calcifications
3	Only calcifications: casting powdery crushed-stone like
4	Others: asymmetric density architectural distortion

If we want to detect with mammography small breast cancers, we have to use the accurate mammographic criteria for early (T1a and T1b) invasive breast cancers. However, there are only a few publications in the literature about the mammographic appearance of breast cancer smaller than 10 mm.⁶ Additionally, there is unfortunately no standardized approach - different authors use different mammographic criteria for breast cancers smaller than 10 mm.

The aim of this study was to determine the most common mammographic findings of small invasive breast cancers (T1a and T1b).

Patients and methods

In the 16 months period (from September 2003 to December 2004) 100 consecutive women (aged 36-77 years; mean 59 years) with 102 pathologically proven small (pT1a and pT1b) breast cancers were treated at the Institute of Oncology in Ljubljana, Slovenia. Most of the cancers were non-palpable (80/102) and detected on screening mammography. Palpable cancers were tumours which were palpable in the same quadrant as histologically proven tumours

and which were cytologically proven for cancer (C5) without imaging modality.

Mammographic lesions were classified according to BIRADS:⁷ 4 lesions as R2, 28 lesions as R3, 66 as R4 and 4 as R5. Free hand fine needle aspiration biopsy (FNAB) was performed in all 20 patients with palpable tumours. Cytology was positive (C5) in 14/20 patients and non diagnostic (C1) in 6/20. In these six patients, as well as in all other cases (80/102) of non palpable tumour, image guided FNAB (58 cases) or core biopsy (28 cases) was performed. In 51 cases biopsy guidance was done by the ultrasound (US) and in 35 by the stereotaxy.

Preoperative diagnosis of breast cancer was established in 67 patients (C5 in 48 cases and B5 in 19 cases) with nonpalpable tumours. Occult lesion localization (40/67 by stereotaxy and 27/67 by US) with 30-60 MBq of ^{99m}Tc labeled nanocolloid (Nanocol®) in 0.2 ml saline was performed on the morning of surgery. Tumourectomy

(58/67), quadrantectomy (3/67) or mastectomy (6/67) were combined with a sentinel lymph node biopsy (SLNB).

In 31 patients with preoperative C3/C4 (22 patients) or B2-4 (9 patients) radioguided occult lesion localization (ROLL) and excisional biopsy were performed. ROLL was performed in 26 cases under stereotaxic and in 5 cases under sonographic control. After the histological diagnosis of breast cancer (B5), in the second surgical procedure re-excision of the primary site (22 patients), quadrantectomy (2 patients) or mastectomy (3 patients) and SLNB was performed. In four patients only SLNB was performed because of adequate margins (more than 10 mm) after the excisional biopsy.

Two patients with palpable cytologically proven breast cancers (C5) underwent tumourectomy and axillary dissection because preoperative US examination and US guided FNAB of the axillary lymph nodes revealed metastases in lymph nodes.⁸

All mammographic images were reviewed by a single radiologist (PM), who has a special interest and dedication in breast radiology. Mammographic findings were classified according to Table 2, as seen in Table 1. A mass is defined as a lesion seen in two different projections, while a density is observed only in a single projection according to Samardar.⁹

Pathologic characteristics of primary tumours included size, histologic type, grade (according to Bloom, Richardson and Elston), status of axillary lymph nodes, estrogen and progesteron receptors and HER2 status. The histological type of breast cancers was as follows: invasive ductal, invasive lobular, tubular, mucinous, medullary and papillary.

For the statistical analysis descriptive statistical methods were used.

Results

The mean size of breast cancers was 8.1 mm (range 4-10 mm; pT1a in 18 and pT1b in 84 cases). Histologically 86/102 (84%) were invasive ductal, 14/102 (14%) invasive lobular and 2/102 (2%) invasive tubular cancers. There were 48/102 (47%) grade I, 41/102 (40%) grade II and 13/102 (13%) grade III cancers. The great majority of patients (98/100) had no metastasis in lymph nodes. Estrogen and progesteron receptors were positive in 91 patients, while there were only 8 patients with positive HER2 tumours.

The most frequent mammographic finding was a stellate mass without calcifications, which was seen in 44/102 (43%) cancers (Table 2). Casting type calcifications were found in 17/102 (17%) cancers.

There were 28 patients younger than 50 years and Table 3 shows mammographic findings in this group of patients. The most frequent mammographic finding was a stel-

Discussion

The most common mammographic finding in small breast cancers (T1a and T1b) in our study was a stellate mass without calcifications. It was found in 44/102 (43%) of small breast cancers. This is consistent with results of other published series.⁶⁻¹⁴ Additional 16/102 (16%) of small breast cancers have mammographic appearance of a round/oval mass without calcifications. Calcifications with/without mass were present in 24/102 (24%) of small breast cancers.

The important finding of our study was that the distribution of mammographic findings in small breast cancers varied with age. In the group of younger women (< 50 years) with higher breast density, a stellate mass without calcifications was still the most common mammographic finding. It

was found in 10/28 (36%) of small breast cancers. However, the proportion of circular/oval shaped tumours was much smaller in this group of women. There was only a single woman (1/28) with a mammographic finding of a circular/oval shaped tumour. On the other hand, calcifications with/without mass are much more common mammographic findings in younger women. In our series, 12/28 (43%) of small breast cancers appeared mammographically as calcifications. Half (6/12) of them with a mass and half of them without it.

More importantly, the majority of calcifications were of the casting type. Tabar⁶ proved by the multivariate analysis that the mammographic appearance of small breast cancers was an independent prognostic factor. In his study the mammographic appearance of casting type calcifications was more predictive of a long-term survival than clas-

Figure 2. Mediolateral oblique view of the right breast with BIRADS category 4. Mammographic finding of 0.8 cm large asymmetric density. Pathologically proven as invasive ductal carcinoma grade 2.

sis prognostic factors (tumour size, histological grade and lymph node status). The 20-year survival rate was 72% for women with small breast cancers accompanied by casting – type calcifications. All other women with small breast cancers had an excellent survival regardless of lymph node status, histological grade or treatment.⁶

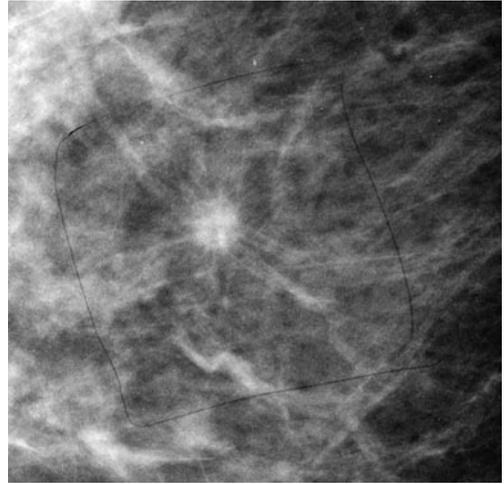

Figure 3. Stellate mass without calcifications on mammography. Histologically proven as 0.5 cm large invasive breast carcinoma, grade 2.

Casting type calcifications are associated significantly with a positive lymph node status and poorer histological grade.⁶ In our series there were only two patients with lymph node metastases. Both of them had tumours accompanied by casting type calcifications. The majority of our patients with small breast cancers accompanied by casting type calcifications also had a higher histological grade (grade III in 7/15 and grade II in 5/15).

Asymmetric breast findings define as four different types: asymmetric breast tissue, densities seen in one projections, ar-

Figure 4. Crushed-stone like calcifications on mammography. Histologically 0.6 cm large invasive breast carcinoma, grade 1.

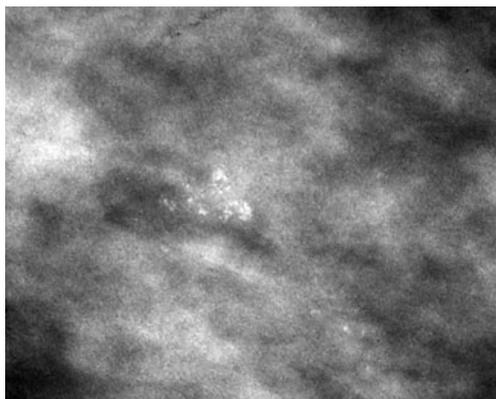

Figure 5. Powdery type of calcifications on mammography. Histologically proven as 0.4 cm large invasive breast cancer, gradus 1.

chitectural distortion, and focal asymmetric densities.^{8,9} We have observed an architectural distortion (a focal area of breast tissue appears distorted with no definable central mass) and a focal asymmetric density also in our study. From 102 small breast cancers, 14 (14%) were seen as a focal asymmetric density and 4 as an architectural distortion. Interestingly, 4/14 (26%) of focal asymmetric density proved histologically to be invasive lobular cancers. Invasive lobular cancers accounts for 5-10% of all breast cancers and can often manifest as an area of distortion or asymmetry.¹⁰ In our series we found 14% of invasive lobular cancer, that in 86% appeared as spiculated mass or focal asymmetric density. There was no case of an invasive lobular cancer which would appear mammographically as calcifications only. This is in agreement with results of Tjurfjell.¹³

Samardar¹⁵ defined that palpable mass associated with a focal area of breast asymmetry or architectural distortion is very often malignant. We found in our series only 20 palpable small breast cancers and they all appeared mammographically as a mass with/without calcifications.

Conclusions

Most of the T1a and T1b breast cancers are nonpalpable. The most common mammographic finding in these cancers is stellate mass without calcifications. Calcifications are more frequent mammographic findings in younger patients. Fourteen % of small breast cancers appear mammographically as a focal asymmetric density. Invasive lobular cancer never appears mammographically as calcifications only.

case report

Obliterative hepatocavopathy – ultrasound and cavography findings

Ramazan Kutlu

Department of Radiology, Inonu University School of Medicine, Malatya, Turkey

Background. Obliterative hepatocavopathy is a relatively new term for the definition of primary inferior vena cava thrombosis and membranous obstruction of inferior vena cava that were included in Budd-Chiari syndrome.

Case report. In this report, cavography and ultrasound findings of a case with a complete occlusion of inferior vena cava in a 36 year-old female patient who has been followed up with the diagnosis of hepatitis B related cirrhosis for 5 years were presented.

Conclusions. Although this disease classically treated by surgery (e.g. portal or mesenteric–systemic shunting, liver transplantation), also interventional radiology procedures e.g. transjugular intrahepatic portosystemic shunting, percutaneous hepatic vein angioplasty and/or stent placement), now play an important role in the management⁴.

Key words: obliterative hepatocavopathy; cavography; ultrasound; inferior vena cava

Introduction

The complete inferior vena cava (IVC) obstruction develops as a result of primary IVC thrombosis.¹ Although in the earlier literature this entity was included in Budd-Chiari syndrome, obliterative hepatocavopathy (OH) is currently being used to define this condition.¹ In this report, we present

cavography and ultrasound features of this rare entity in a 36 year-old female patient.

Case report

A 36 year-old female patient who has been followed with the diagnosis of chronic liver disease (Child B, score 7) due to hepatitis B for 5 years was referred to our radiology department for portal Doppler evaluation. She had splenomegaly and moderate ascites. Upper gastrointestinal endoscopy revealed esophageal varices. She had been receiving beta blockers and diuretics. Her CA-125 level was found to be increased (234 U/mL).

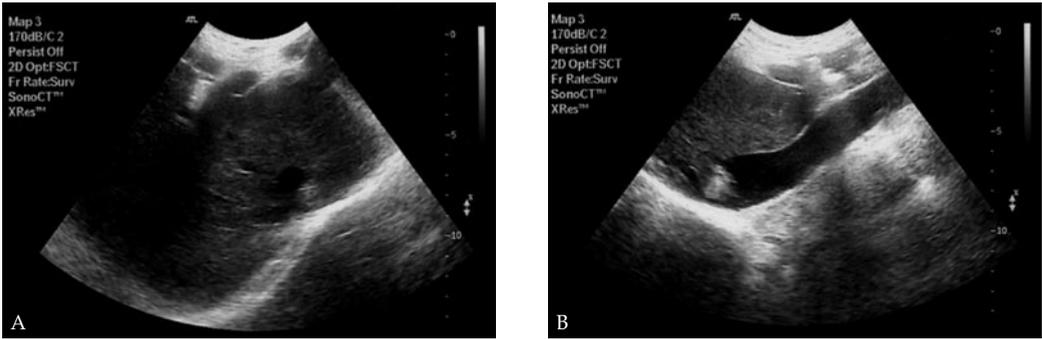

Figure 1. Gray scale axial (A) and sagittal (B) US images show hyperechoic, solid material at the posterolateral part of distal IVC.

Gray scale (Figure 1 A,B) and Doppler (Figure 2 A-C) US examinations showed compressed hepatic veins, hepatopedal portal flow, and no blood flow into the right atrium through distal IVC which was thrombosed. The abdominal CT examination revealed the absence of intrahepatic portion of IVC. The patient didn't undergo

MR examination due to claustrophobia. Cavography was performed using right femoral vein access. Firstly, a large vein was erroneously accessed and a test injection before introducer placement demonstrated that this vein was a large collateral vein extending to the right side of the body and ultimately draining to the intercostal, pericardiophrenic and right subclavian vein (Figures 3 A-E). Secondly, the right femoral vein was catheterized and inferior cavography revealed a complete occlusion of distal 4 cm of IVC connecting to the right atrium and retrograde flow into the prominent collaterals in the late series (Figures 4 A,B). The selective catheterization of the hepatic veins showed hepatic vein confluence and weak filling (Figure 5A) and a small vein below hepatic confluence draining to IVC (Figure 5B). Superior vena cavography

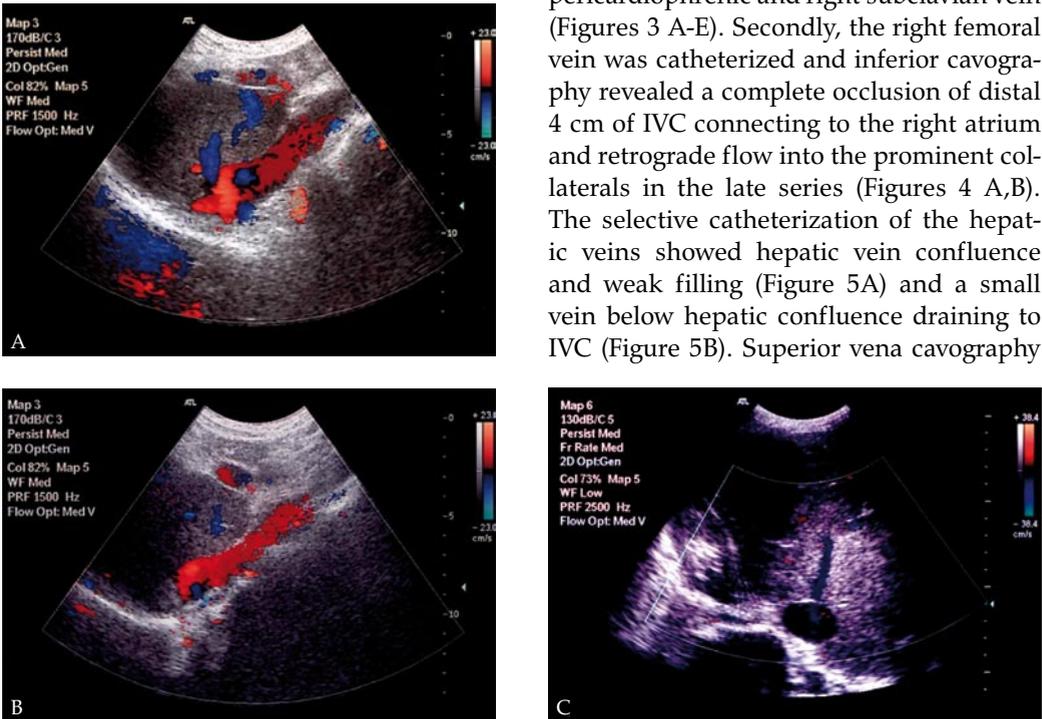

Figure 2. Sagittal (A, B) Doppler US images slight filling of hepatic vein and complete occlusion of distal IVC. Subcostal oblique image (C) reveals a relatively small hepatic vein below the hepatic confluence.

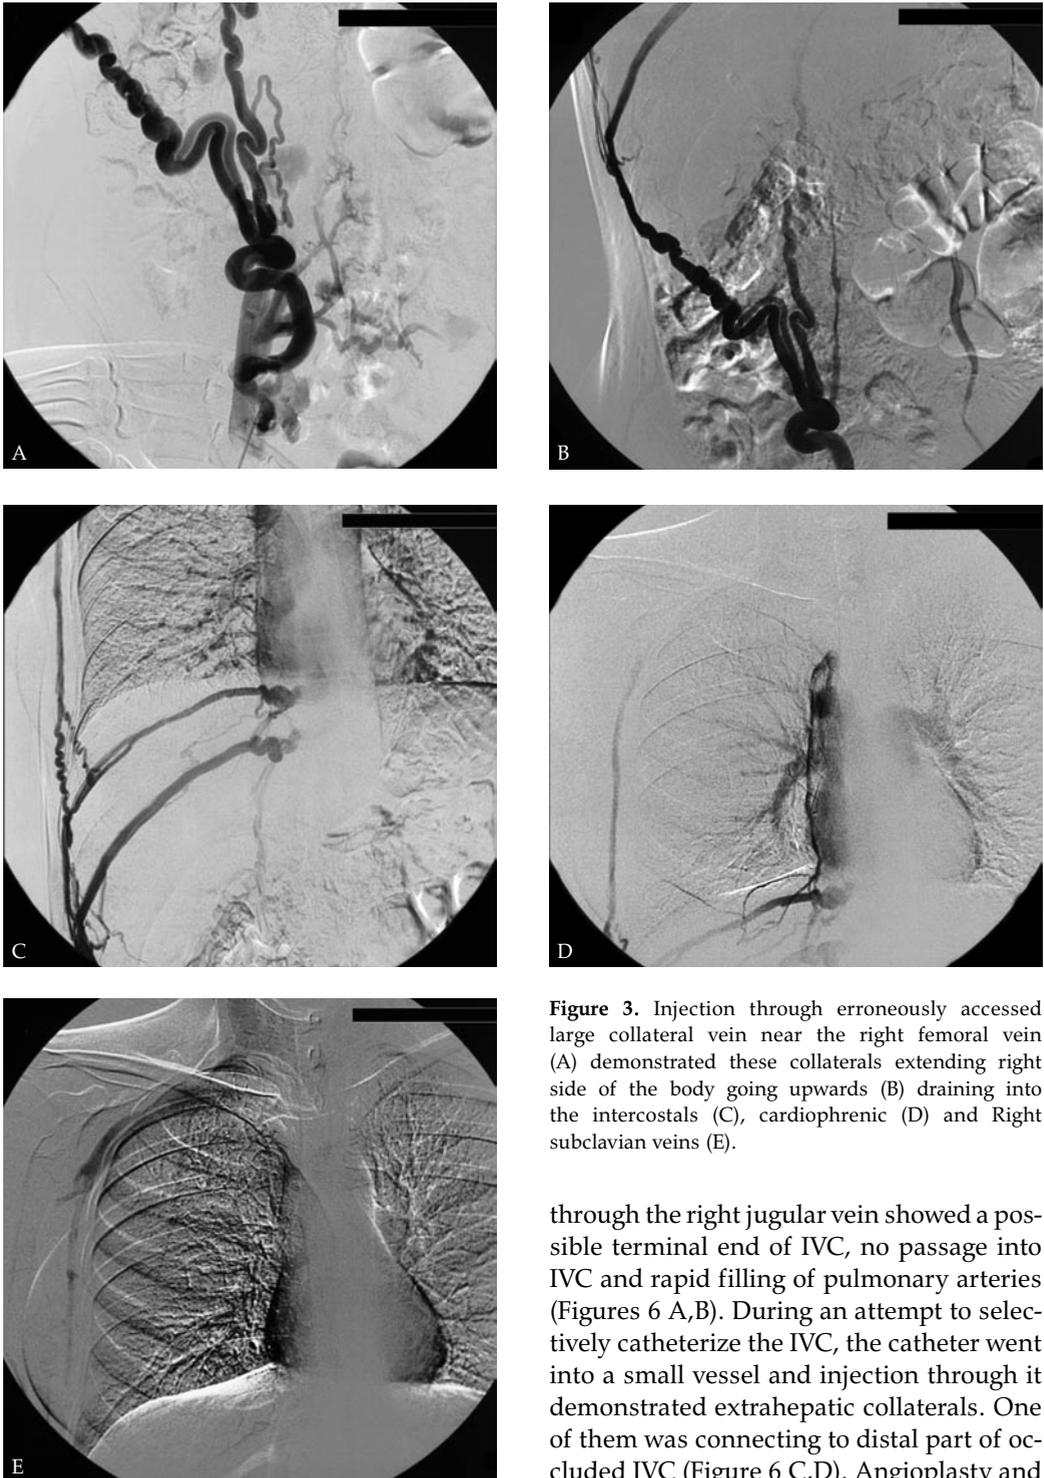

Figure 3. Injection through erroneously accessed large collateral vein near the right femoral vein (A) demonstrated these collaterals extending right side of the body going upwards (B) draining into the intercostals (C), cardiophrenic (D) and Right subclavian veins (E).

through the right jugular vein showed a possible terminal end of IVC, no passage into IVC and rapid filling of pulmonary arteries (Figures 6 A,B). During an attempt to selectively catheterize the IVC, the catheter went into a small vessel and injection through it demonstrated extrahepatic collaterals. One of them was connecting to distal part of occluded IVC (Figure 6 C,D). Angioplasty and

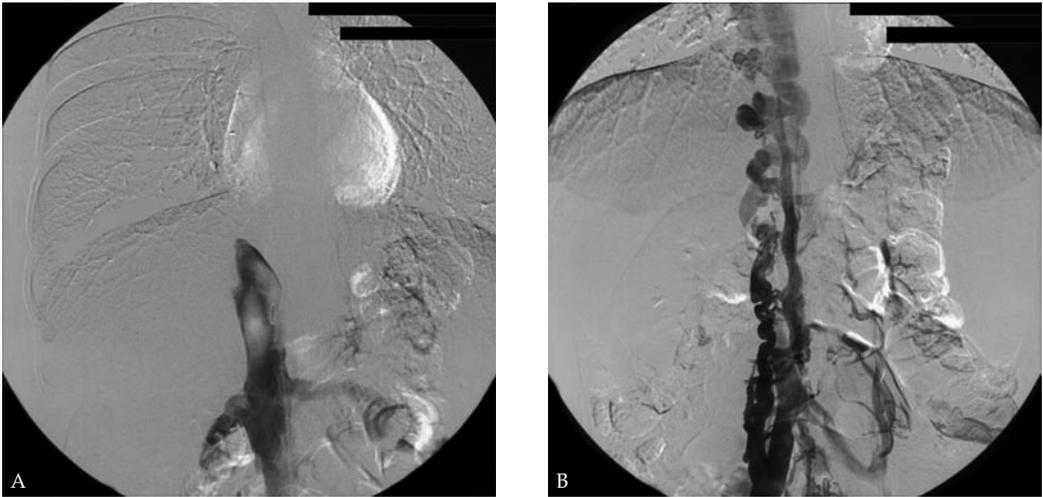

Figure 4. Cavography performed with 6F pigtail catheter which could not be passed into right atrium showed complete occlusion of distal IVC (A). Due to downward flow in the late series, markedly dilated and tortuous paraspinous collaterals were seen (B).

stent placement were considered but the patient did not accept the intervention.

Discussion

OH is a relatively new term proposed to define primary IVC thrombosis and membranous obstruction of the IVC.¹ These two

conditions were included in Budd-Chiari syndrome which was defined as hepatic venous outflow obstruction at any level from the small hepatic veins to the junction of the IVC and the right atrium, regardless of the cause of obstruction.² Occlusion and stenosis of the IVC are sequelae of primary IVC thrombosis.¹ Although the majority of these cases are idiopathic, as in our case,

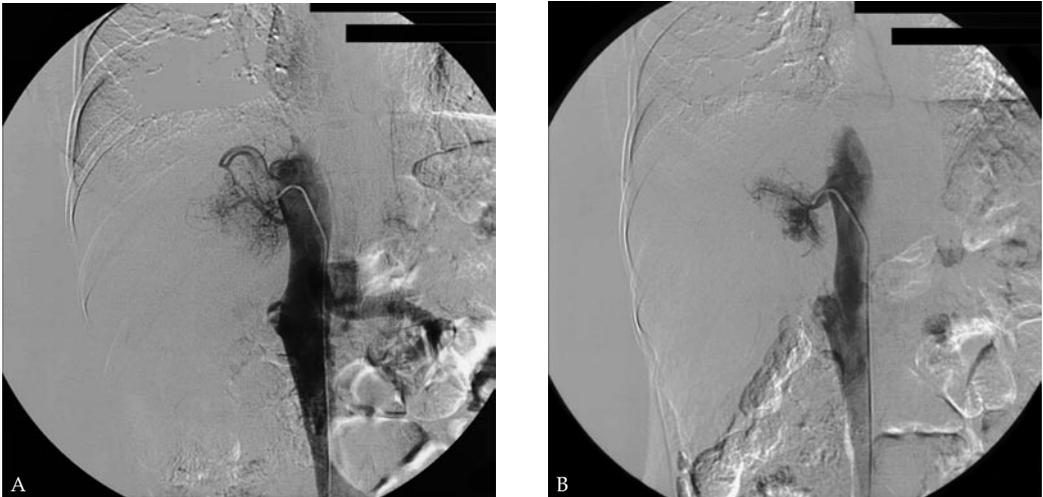

Figure 5. Selective hepatic vein injection showed a part consistent with hepatic vein confluence and a tangle of vessels in the area of hepatic veins (A) and a small vein that had been seen during Doppler examination (B).

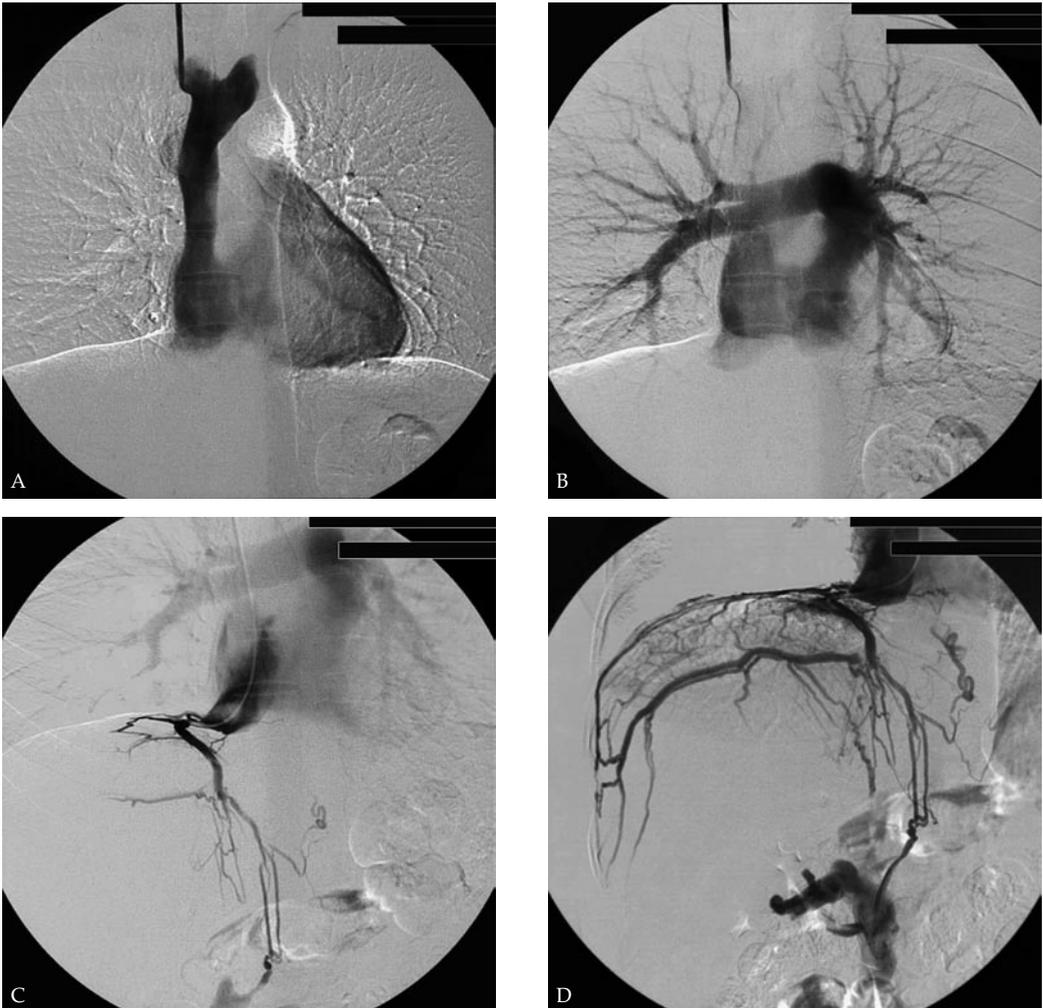

Figure 6. Superior venacavogram through introducer in right jugular vein shows no passage into IVC (A) and rapid filling of pulmonary arteries (B). Selective catheterization with a multipurpose catheter shows extrahepatic collaterals and filling of pulmonary arteries due to backflow (C), and in the later phases collateral connecting to occluded distal IVC appears and than IVC fills.

thrombotic or hypercoagulable conditions (like coagulation factor deficiency or mutation, myeloproliferative disorders, oral contraceptive use, pregnancy etc) could be observed in OH.¹ If all hepatic veins become occluded, blood is coming from hepatic artery drain into either portal veins or collateral vessels. Retrograde flow in the portal vein occurs and portocaval shunts develop. As the occlusion progresses, blood circulation changes appear in and around

liver. Intrahepatic or subcapsular hepatic venous collaterals are a distinctive feature of Budd–Chiari syndrome.^{2,3} In complete IVC obstruction, large shunts form between the IVC and the ascending lumbar vein continuous with the azygos and hemiazygos veins or paravertebral veins. The increased pressure in the ascending lumbar/hemiazygos and azygos veins may result in retrograde flow in the intercostal and subcutaneous veins.

Due to mainly difficulties in the differential diagnosis of primary hepatic vein thrombosis and primary IVC thrombosis, the epidemiology of primary IVC thrombosis is not well established and adults are affected more frequently, but OH could be seen at any age.¹ The clinical presentation is acute and very serious like in the case of vena cava superior sindrom.^{1,4} Hepatomegaly, ascites, abdominal pain, fever and leg oedema appear quite fast, but the clinical course could be chronic with repeated acute episodes characterized by ascites, hepatomegaly, and pain.¹ Due to the circulatory disturbances caused by IVC obstruction, patients commonly show marked venous dilatation over the body trunk.¹ Our case had no visible venous dilatation over the body trunk possibly due to the collateral between occluded distal IVC and right atrium.

The radiological imaging provides a definitive diagnosis of OH. In addition to demonstrating thrombus within the IVC and hepatic vein problems, ultrasonography also demonstrates caudate lobe enlargement, splenomegaly, ascites, stenotic veins, membrane, intrahepatic collateral veins connecting with enlarged hepatic veins, vein to-vein anastomoses, a patent and enlarged inferior right hepatic vein opening into the IVC, and absence of normal respiratory changes in the IVC. Doppler US could delineate flow disturbances and direction. CT and MRI assess hepatomegaly, ascites, enlarged caudate lobe, splenomegaly, collateral vessels, and the thrombus occluding the IVC. MRI depict the level of an obstructing membrane or web within the IVC.¹ Hepatic venography delineates occluded veins, slow flow in attenuated venous branches, and rapid shunting into the portal vein. Additionally, wedged hepatic venography will demonstrate the "spider's web" network.¹ Cavography is one of the most important imaging modality in the evaluation of IVC obstruction. It confirms the level of

obstruction, occluding thrombus, mural thrombosis, membrane, and extrahepatic collateral vessels.¹ Based on cavography findings three types of IVC obstruction were defined; type I, a thin membrane is present in the vena cava, type II, there is an absent segment of the IVC of variable length, type III, the vena cava is not visualized, and only dilated collateral channels are demonstrated.² According to this classification, our case appears to be type II.

Although this disease classically treated by surgery (e.g. portal or mesenteric-systemic shunting, liver transplantation), interventional radiology procedures e.g. transjugular intrahepatic portosystemic shunting, percutaneous hepatic vein angioplasty and/or stent placement also plays an important role in the management – like in the others severe vascular complicated cases.^{3,5,6}

Background. Gastrointestinal stromal tumours (GISTs) are the most common mesenchymal tumours of the digestive tract. These tumours can not be simply divided into benign and malignant forms. There is a continuum from benign to malignant forms. The tumour size and mitotic activity have strong influence on GISTs behaviour. Tumour behaviour also varies according to the site of the origin. The site of the tumour origin can be anywhere along the digestive tract, in the mesentery or omentum. GISTs are mainly benign tumours, about 70-80%, usually found in the gastric wall. We report a case of 70-year old female with gastric form of GIST.

Case report. The patient has undergone abdominal ultrasound (US) because of a palpable lump in the epigastrium, which mainly revealed hyperechogenic round mass with small hypoechogenic areas in the central part. On the abdominal computed tomography (CT) a large expansive mass with heterogeneous structure was depicted in the gastric wall. The mass had higher attenuation coefficients on the periphery and lower in the central part. During the surgery the large exophytic tumour of the gastric wall has been found. The diagnosis of gastric GIST has been obtained after the pathohistologic and imunohistochemical analysis.

Conclusions. Gastrointestinal stromal tumours may be the statistically rare tumours (0.1%-0.3% of all gastrointestinal tumours) but when we have the patient with a round, mainly exophytic mass on the wall of the gastrointestinal tract or peritoneum, GIST must be taken into consideration. Cross-sectional imaging methods like US and CT allow the preoperative diagnosis of the tumour and staging.

Key words: gastrointestinal stromal tumours; computed tomography

Introduction

Gastrointestinal stromal tumours (GISTs) are currently defined as mesenchymal tumours of the gastrointestinal tract, mainly KIT (CD117)-positive.¹ These tumours usually affect the population over 50 years, rarely patients younger than 40 years of age, and are extremely rare in the child-

hood.¹⁻³ The frequency of GISTs is about 10 to 20 cases per million persons, according to the Miettinen and Lasota.⁴ GISTs can arise anywhere through the gastrointestinal tract but they can also occur in the *omentum*, mesentery and *retroperitoneum* as a primary tumour. In 70% of cases GISTs arise in stomach, the second most frequent site is small intestine (20-30%). Other less frequent sites are anus, rectum, colon and oesophagus.⁴ GISTs of gastrointestinal tract commonly arise in the *muscularis propria* of the stomach or intestinal wall, usually in the outer muscular layer. That is the reason why GISTs have an exophytic growth pattern in majority of the cases and usually manifest themselves as large extraluminal abdominal masses. Clinical features of GISTs depend on the size and anatomic location of the tumour. They can be presented with mild signs and symptoms of anaemia caused by occult bleeding in the gastrointestinal tract or they can have a dramatic picture with *hematemesis*, *melena*, abdominal pain and signs of intestinal obstruction.^{5,6}

Histogenetically gastrointestinal stromal tumours probably originate from interstitial cells of Cajall (or the native KIT-positive gut pacemaker cell) which intermediates between the GI autonomic nervous system and smooth muscle cells regulating GI motility and autonomic nerve function. This postulate is made on the expression of KIT on GISTs tumour cells.^{1,7}

Larger forms of GISTs are usually centrally cystic, positioned extraluminally, while smaller GISTs are subserosal and intramural solid tumours, rarely polypoid intraluminal ones.¹ GISTs can generally be divided into three groups: spindle cell type (70%), epithelioid type (20%) and mixed spindle and epithelioid cell type.⁷ Gastric GISTs can be histologically divided into two groups, four spindle cell subtypes (sclerosing spindle cell, palisaded-vacuolate spindle

cell, hypercellular spindle cell, sarcomatous spindle cell) and four epithelioid subtypes (sclerosing epithelioid GIST with syncytial pattern, epithelioid GIST with dyscohesive pattern, hypercellular epithelioid GIST, sarcomatous epithelioid GIST). Sarcomatous subtype is highly cellular form of GIST with a marked mitotic activity (more than 20 per 50 HPFs).⁹ The most important feature for immunohistochemical differentiation between GISTs and other similar soft-tissue tumours are the antigens on the surface of the tumour cells, especially KIT tyrosine kinase receptor (CD117) which has been found in more than 95% of GISTs. There are other antigens which are less specific for GISTs but are commonly expressed, like CD34 and nestin. GISTs sometimes express smooth muscle cell markers (like smooth muscle cell actin-SMA), but are usually negative for desmin, the muscle type intermediate filament protein.¹ KIT immunoreactivity has shown to be very useful in the treatment of GISTs with immunotherapy as well as in diagnostics. The immunotherapy of GISTs is based on targeting of tyrosine kinase receptors with a selective KIT-tyrosine kinase inhibitor (STI-571, imatinib mesylate). The drug acts as a selective c-kit blocker.⁶

The contrast-enhanced computed tomography (CT) is currently widely available diagnostic imaging method and the imaging modality of choice for patients with abdominal mass suspected for GISTs.⁷

The standard initial treatment for GISTs, even in non-resectable cases, is the surgical treatment. Some authors propose the immediate treatment with imatinib for unresectable and/or metastatic disease.⁸

Case report

A 70-year old female patient underwent abdominal ultrasound (US) because of pal-

Figure 1. Abdominal ultrasound – axial plain. Large round hyperechogenic expansive mass (white arrow) with small hypoechogetic areas in the central part (white notched arrow).

pable mass in the upper abdomen. The patient suffered from inapetency without vomiting and weight loss, hematemesis or melena. US revealed a large round hyperechogenic expansive mass with small hypoechogetic areas in the central part. There were no signs of focal lesions in parenchymal abdominal organs or lymphadenopathy (Figure 1).

The next step in diagnostics was computed tomography (CT) of the abdomen, performed with three postcontrast phases and distension of gastrointestinal (G-I) tract with 1000ml of water. CT depicted a large intraperitoneal mass in the upper abdomen, ventrally placed and sharply demarcated from surrounding structures except from stomach. The lesion had a heterogeneous structure on native and postcontrast scans with higher attenuation coefficients on periphery and lower in the central part (about 30HU on precontrast and 60HU on postcontrast scans). There were no significant changes in attenuation values centrally between precontrast and all series of postcontrast scans. No lymphadenopathy

or focal lesions in the parenchymal organs have been found. The working (imaging) diagnosis of mesenchymal tumour of the stomach wall (probably GIST) has been established (Figure 2).

The upper G-I tract follow through with barium showed elongated stomach with sharply demarcated contours and concavely impressed lesser curvature (Figure 3).

The patient has been treated surgically with a complete gross resection. During the explorative laparotomy a large tumour in the upper abdomen with origins on the lesser curvature of the stomach without lymphadenopathy has been found (Figure 4).

The material obtained during surgery has been sent to the pathohistologic analysis and immunochemical evaluation. The gross pathologic feature of the specimen was an encapsulated mass of medium firm consistency, measuring 18 cm in largest diameter. On cut section the tumour was whitish and greyish with dispersed areas of swirling structure. Predominant histological features were spindle shaped cells with scant cytoplasm and big nucleus without nucleolus. The tumour cells formed swirling structures and tracks. Focal areas of degeneration and small areas of tumour tissue necrosis were found.

Three mitoses per 50 consecutive high power fields (HPF) have been detected.

The immunohistochemical analysis showed that the tumour cells were CD117(C-kit), CD 34 and BCL2 positive, SMA -/+ and S-100 negative. The diagnosis of gastrointestinal stromal tumour was established.

Discussion

GIST is usually placed in the stomach and small intestine. The gastric form is especially common between other possible locations, 50 to 70% of GISTs are located in the stomach, 33% of cases in the small

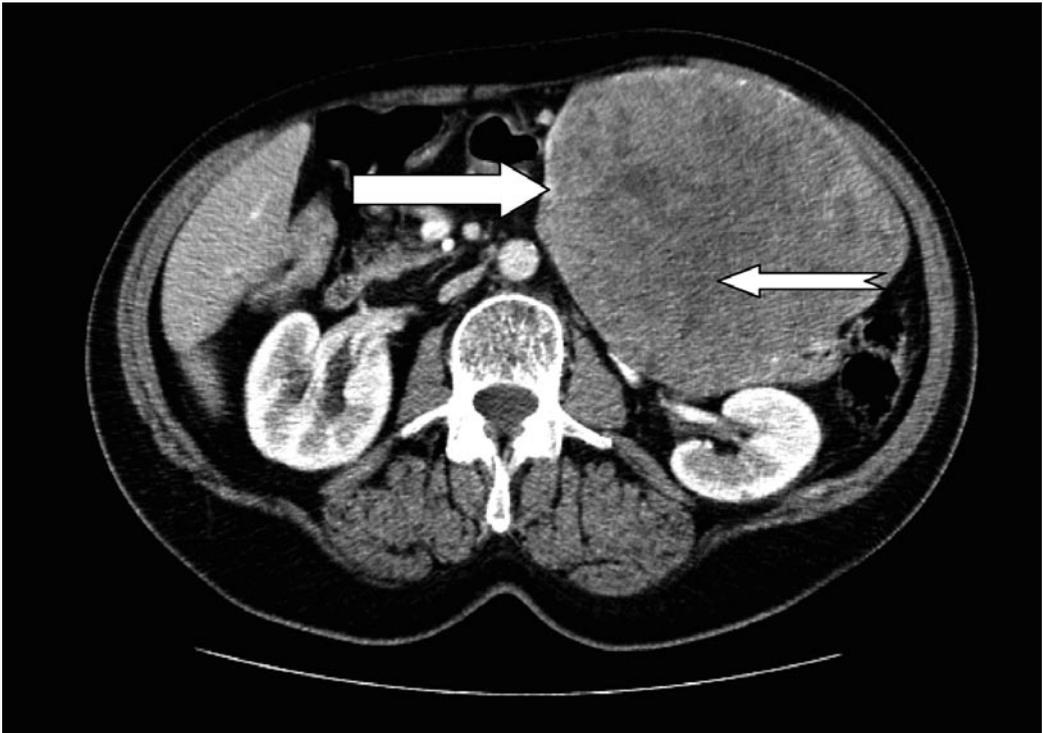

Figure 2. Abdominal CT post-contrast axial scan. Large round expansive mass in the upper abdomen with heterogeneous structure sharply demarcated from surrounding structures depicted on this scan. Higher attenuation coefficients on periphery (white arrow) and lower in the central part were detected on native and postcontrast scans (white notched arrow).

intestine, 5 to 15% in rectum and colon and only 1 to 5% in oesophagus.^{2,10} GISTs can originate outside of the gastrointestinal wall, in mesentery or peritoneum in 10% of cases, but they are extremely rare retroperitoneally. Both sexes are equally affected by GISTs, commonly between 40 and 70 years. The small intestine GISTs are usually more aggressive and have a more grave prognosis than GISTs which originate in other segments of G-I tract.^{3,11}

The factors that worsen the prognosis of GISTs are location (all extragastric locations), size of the tumour (bigger than 5cm), advanced age of the patient, metastasis at the time of tumour manifestation, tumour tissue necrosis and high mitotic index (more than five mitosis per 50 high-power fields).^{4,10,11} In 10 to 30% of GISTs

malignant forms have been diagnosed.⁴ The two most important factors that influence GISTs prognosis are the tumour size and mitotic index. Currently it is believed that only tumours with diameter smaller than 1 cm can be considered as definitely benign on clinicopathologic features.¹² The patient presented in this report has few bad prognostic factors, age of 70 years and the tumour largest diameter of 18 cm.

Clinical features of GISTs depend on the tumour size and anatomic location of the tumour, they can be mild signs and symptoms of anaemia caused by occult bleeding in the gastrointestinal tract or dramatic picture with hematemesis, melena, abdominal pain and signs of intestinal obstruction.⁵ GIST of the stomach, small and large intestine and anorectum usually manifest with gas-

trointestinal bleeding from mucosal ulcerations. The other common clinical features are abdominal pain, nausea, dysphagia, vomiting, weight loss and palpable abdominal mass.^{13,14} The leading clinical feature of the case presented in this article was palpable abdominal mass in the epigastrium. G-I tract obstruction can be manifested in 10 to 30% of cases, usually in the cases of the small intestine GIST. The biliary tract and the renal obstruction may be the clinical feature of the duodenal GIST.^{13,15}

The tumour is usually covered with an affected organ serosa. In the cases of the surrounding structures infiltration by the GIST the primary tumour has more often smooth and broad pushing than insinuating fascicles. The typical location of the first recurrence of GIST is in the abdomen. Liver is the most common metastatic site, in 65% of cases. The lung and bone metastases usually develop later than liver metastases. Lymph node metastases are very rare for the difference to lymphoma and leiomyosarcoma.^{1,12,16}

Computed tomography (CT) and magnetic resonance imaging (MRI) are used for the radiologic diagnostic evaluation of patients with abdominal mass suspected for GIST. Contrast-enhanced CT is currently an imaging method of choice for diagnosing of GISTs, staging and surgical planning because of its wide availability. Endoscopic ultrasound can be used for the evaluation of the local extent in patients with small tumours which have been found incidentally during endoscopy. MRI is a better imaging method for the evaluation of patients with rectal GISTs. MRI is indicated for the evaluation of liver lesions which can not be characterized definitely on CT scans and in cases of contrast-enhance CT is contraindicated.^{8,17,18} The factors that influence CT features of GISTs are size of the tumour, aggressiveness of the tumour and time of presentation during the course of

Figure 3. Upper gastrointestinal tract follow through with barium - anteroposterior projection - elongated stomach with sharply demarcated contours and concavely impressed lesser curvature.

the disease.¹⁸ The typical CT finding of primary GIST is a large mass with heterogeneous structure because of usually centrally placed necrosis, haemorrhage, or cystic degeneration. In fact, the tumour can be so large that it is difficult to define its origin. On postcontrast scans the tumour is usually presented as a hypervascular and well-enhancing heterogeneous mass. Ulceration and fistulisation to the lumen of GI tract are often seen in GIST patients. Small GISTs are commonly presented as homogenous masses.¹⁸ MRI can be used to follow-up the operated patients and to evaluate response in the patients on an adjuvant therapy with imatinib. Fluorine-18-fluorodeoxyglucose (FDG) positron emission tomography (PET) is recommended in patients on imatinib therapy which need an early detection of tumour response to imatinib because of the possibility for the surgical resection after the cytoreduction with imatinib.¹⁷ There is no need to perform PET scan in every GIST patient after the complete surgical resection of the tumour. PET can be performed

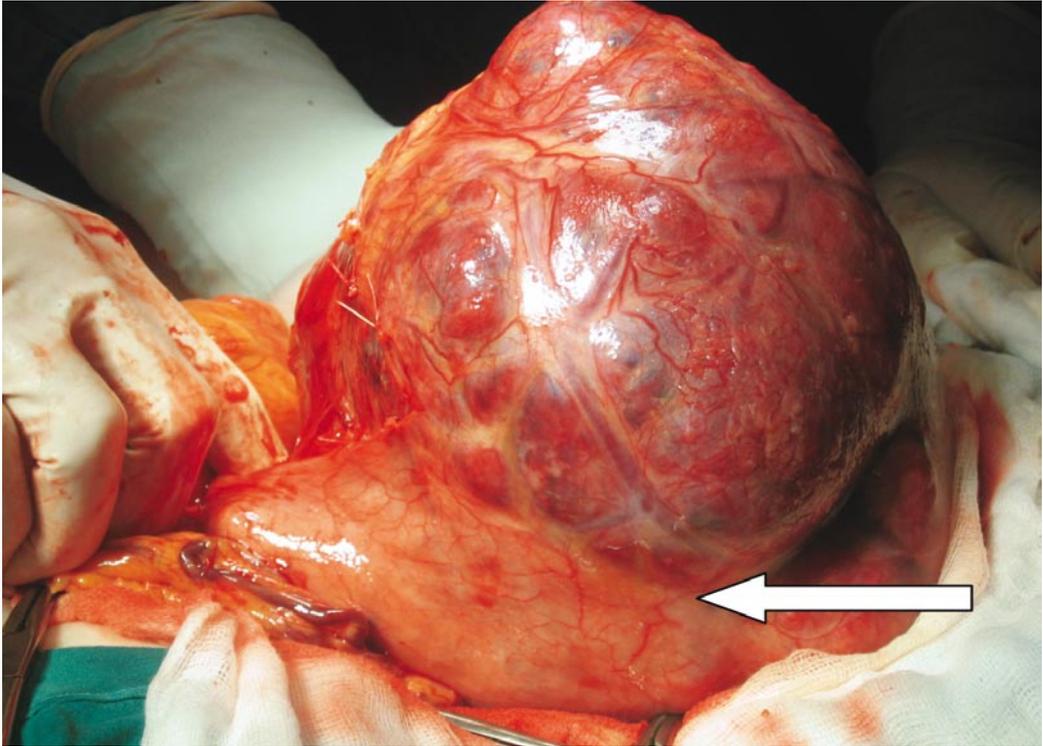

Figure 4. Explorative laparotomy – a large tumour in the upper abdomen with origins on the lesser curvature of the stomach (white arrow).

on patients with CT or /and MRI images suspected for metastases.^{8,17,18}

The imaging diagnosis of GIST can be suggested when CT depicts a large, mainly extraluminal tumour arising from the stomach or small bowel wall with heterogeneous contrast material enhancement (with higher attenuation coefficients peripherally and lower coefficients in the central part). Metastases are usually presented in the liver and on the peritoneum, but a lymph node enlargement is very rarely depicted.^{18,19,20} A triphasic CT scanning technique with scanning of the native scans and post-contrast scans after the intravenous injection of contrast material in an arterial and a porto-venous phase with delays of 20-30 s and 70-80 s, respectively, is preferred for baseline scans and follow-ups during and after the treatment.^{17,18}

Unlike GISTs, lymphomas usually cause lymph node enlargement and circumferential bowel wall thickening which homogeneously enhances on post-contrast scans. Carcinoid tumours commonly arise in the terminal ileum often stimulating a desmoplastic reaction with calcifications. A local infiltration and a visceral obstruction are common radiologic features of the carcinoma, very often in large tumours. Metastases of the bowel wall are usually multifocal masses in patients with a history of primary known malignancy.^{18,20,21}

It is still difficult to make a differentiation between GIST and other soft-tissue tumours like leiomyosarcoma, intraabdominal fibromatosis of the bowel wall, malignant tumours of nerve sheath and the tumours of vascular origin with radiological and pathological methods.²¹

Pathohistology accomplished with immunohistochemistry still remain the gold standard for diagnosing of GIST. The transabdominal biopsy is not recommended because of the possibility of seeding the tumour cells.¹⁶

GISTs are commonly positive for KIT (CD117), a tyrosine kinase growth factor receptor. KIT positivity is usually strong and pancytoplasmic, but some epithelioid forms of GISTs of the stomach may be weakly CD117 positive or even negative.¹ We must be aware and analyse the KIT positivity together with other clinical signs, imaging method findings and immunohistochemical test results because there are few other tumours which are generally CD117 positive like small cell carcinoma of the lung, mastocytoma, seminoma and extramedullary myeloid tumour. Tumours like metastatic melanoma, clear cell sarcoma, Ewing sarcoma family of tumours, childhood neuroblastoma and angiosarcoma also sometimes express CD 117.²²

Among other GIST markers CD34, the hematopoietic progenitor cell antigen plays an important role because it can be found in 80 to 85% of gastric GISTs and 50% of small intestinal GISTs. CD34 is usually expressed on endothelial cells, subsets of fibroblasts and neoplasms related to these cell types.⁹ Small intestinal GISTs more often than gastric GISTs express muscle cell markers like SMA. Smooth muscle fibers can be interspersed with SMA and desmin positive GIST intratumoral spindle cells during the infiltration of tumour; in this situation we can have a false muscle marker positivity. The SMA positivity is a favourable prognostic factor for the gastric and small intestinal forms of GIST. The detection of S100 protein is relatively rare in GISTs, it seems to be an adverse prognostic factor in gastric GISTs.^{1,9} Nestin is a type VI intermediate filament protein typical of many stem cells which can be found in

most of the cases of GISTs but also in GIST schwannomas.²³

The surgical resection is the standard initial treatment for GISTs. Until the beginning of an application of imatinib (the specific tyrosine kinase inhibitor) in GIST therapy, surgery was the only way of the treatment because the conventional chemotherapy and the radiation therapy proved inefficient. Generally speaking about 85% of patients with primary localized form of GIST, they can be treated with a complete gross resection, but approximately 50% of those patients develop the tumour recurrence.¹² The patient presented in this article was treated with a complete resection of the tumour. The application of imatinib mesylate for the GIST treatment was a successful introduction of molecularly targeted therapy for the treatment of solid tumours. The imatinib therapy is used for the treatment of unresectable cases, recurrent or metastatic cases. Surgery or ablative modalities can be used when the disease becomes amenable to gross resection due to changes initiated by imatinib, or when the tumour develops resistance to imatinib treatment.^{8,12} The evaluation of the GIST treatment with imatinib mesylate is usually performed with CT, sometimes with ¹⁸FDG-PET. The problem in the evaluation of the GIST treatment with imatinib mesylate is that they correlate poorly with currently internationally agreed classifications for the evaluation of response to the treatment of solid tumours like the World Health Organization criteria or the Response Evaluation Criteria in Solid Tumors (RECIST) criteria. It is suggested that changes in tumour density on CT scans are better modes of assessment of the response to the imatinib treatment than an internationally agreed guidelines. The minority of patients with GIST, less than 15%, have a primary resistance to imatinib mesylate. Half of the patients will develop resistance 2 years after the initiation of the

imatinib treatment, usually because of the secondary KIT mutation.¹² Generally, the median time of recurrence of GISTs after the surgery is 19 to 25 months with the 5-year survival rate about 50%.¹¹

GIST may be statistically rare mesenchymal tumour of the gastrointestinal tract, but whenever the large heterogeneous, abdominal mass with higher attenuation on periphery and lower in the central parts is depicted on the contrast-enhanced CT scans, GIST must be firstly put on the differential diagnosis list. That is important because the transabdominal biopsy of the tumour is not recommended because of the possibility of seeding the tumour cells.¹⁶

review

Time dependence of electric field effects on cell membranes.

A review for a critical selection of pulse duration for therapeutical applications

Background. Electropulsation is one of the non-viral methods successfully used to transfer drugs and genes into living cells *in vitro* as *in vivo*. This approach shows promise in field of gene and cellular therapies. This presentation first describes the temporal factors controlling electroporation to small molecules (< 4kDa) and then the processes supporting DNA transfer *in vitro*. The description of *in vitro* events brings our attention on the processes occurring before (s), during (ms) and after electropulsation (ms to hours) of DNA and cells. They all appear to be multistep events with well defined kinetics. They cannot be described as just punching holes in a lipid matrix in a two states process.

Conclusions. The faster events (may be starting on the ns time scale) appear to be under the control of the external field while the slower ones are linked to the cell metabolism. Investigating the associated collective molecular reorganization by fast kinetics methods and molecular dynamics simulation will help in their safe developments for the *in vivo* processes and their present and potential clinical applications.

Key words: electropulsation; electroporation; electrotransfection; electropermeabilization

Introduction

The application of electric field pulses to cells leads to the transient permeabilization of the membrane (electroporation).¹ This phenomenon brings new properties to the cell membrane: it becomes permeabilized, fusogenic and exogenous membrane

proteins can be inserted. It has been used to introduce a large variety of molecules into many different cells *in vitro*.^{2,3} Clinical applications of the electroporation are now under development as a results of the EU Cliniporator and Esope programs. A local antitumoral drug delivery to patients (a method called electrochemotherapy) is under clinical trial.⁴⁻⁸ Transdermal drug delivery is obtained *in vivo*.⁹ More recently, electroporation has been also used to transfer DNA *in vivo*, into the skin, liver, melanoma and skeletal muscle cells.¹⁰⁻¹⁵ It

has the main advantages of being easy to use, fast, reproducible and safe.

While during 30 years due to technological limits, pulse duration was always larger than 1 microsecond, the recent availability of high voltage (tens of kV) nanosecond long pulse generators opens the way to a new approach. Very fast perturbations under strong fields are induced in the membrane organization.^{16,17} A new field of development is now present for electroporabilization and promising results for clinical applications were reported.

One of the limiting problems remains that very few is known on the physicochemical mechanisms supporting the reorganisation of the cell membrane. The molecular target of the field effect remains unclear.

The present review focuses on the critical role played by the pulse duration in the electroporabilization to small molecules (< 4kDa) and on its support to the processes associated to DNA transfer *in vitro*. Pulse durations are easy to adjust for an optimization of the clinical target: electrochemotherapy, irreversible electroporabilization or gene therapy as suggested as a final conclusion.

Electroporabilization

Theory of membrane potential difference modulation.

An external electric field modulates the membrane potential difference.¹⁸ From the physical point of view, a cell can be described as a spherical capacitor which is charged by the external electrical field. The transmembrane potential difference induced by the electric field, $\Delta\Psi_i$ is a complex function $g(\lambda)$ of the specific conductivities of the membrane (λ_m), the pulsing buffer (λ_{out}) and the cytoplasm (λ_{cvt}), the membrane thickness and the cell size. Thus,¹

$$\Delta\Psi_i = f. g(\lambda). r. E. \cos\theta \quad [1]$$

in which θ designates the angle between the direction of the normal to the membrane at the considered point on the cell surface and the field direction, E the field intensity, r the radius of the cell and f , which is a shape factor (a cell being a spheroid). Therefore, $\Delta\Psi_i$ is not uniform on the cell surface. It is maximum at the positions of the cell facing the electrodes. These physical predictions were checked experimentally by videomicroscopy by using the potential difference sensitive fluorescent probes.¹⁹⁻²¹

The pulse duration plays a critical role when shorter than the capacitive loading time of the membrane. In the previous part of the paper, it was considered that the pulse was long enough to bring the potential steady state value. The loading time τ_{load} brings a limit in this description.¹

$$\Delta\Psi_i = f. g(\lambda). r. E. \cos\theta (1 - \exp(-t / \tau_{load})). [2]$$

Assuming that the membrane is a true dielectric with no electric leak, the loading time. τ_{load} , is given by

$$\tau_{load} = rC_m (1/2\lambda_{out} + 1/\lambda_{cvt}) \quad [3]$$

C_m is the membrane capacitance, λ_{out} and λ_{cvt} , respectively, the conductance of the external buffer and of the cytoplasm. τ_{load} is longer for larger cells in a heterogeneous population. Longer pulses are needed to reach the asymptotic electrically induced transmembrane voltage value (Eq. 1). A key assumption in this physical description is that the electric pulse is a sharp square wave.²² This description is under the assumption that the cell is a sphere. A more complex description is needed for spheroidal cells and their orientation relative to the field has to be taken into account.^{23,24}

The membrane leakiness affects the loading time of the membrane when the field is applied.¹ Its physical definition is given in²⁶ by:

$$\tau = r C_m (\lambda_{\text{cyt}} + 2\lambda_{\text{out}}) / (2 \lambda_{\text{cyt}}\lambda_{\text{out}} + r\lambda_m (\lambda_{\text{cyt}} + 2 \lambda_{\text{out}})/d) \quad [4]$$

As λ_m is dependent on the membrane leakiness, the loading time of the membrane will decrease with an increase in the membrane leakiness. The pulse duration plays a more critical role in such a case. But under physiological conditions, where λ_{out} is larger than 10 mS/cm, as λ_{cyt} is about 4 mS/cm, τ_{load} is always of the order of 1 μ s for mammalian cells

Critical parameters affecting electropermeabilization

Effects of the electric field parameters. When the resulting transmembrane potential difference $\Delta\Psi$ (i.e. the sum between the resting value of cell membrane $\Delta\Psi_0$ and the electroinduced value $\Delta\Psi_i$) reaches threshold values close to 250 mV, membranes become permeable.²⁵⁻²⁶

Permeabilization is controlled by the field strength. Field intensity larger than a critical value (E_p) must be applied to the cell suspension. From Eq. [1], permeabilization is first obtained for θ close to 0 or π . E_p is such that:

$$\Delta\Psi_{\text{perm}} = f g (\lambda) r E_p \quad [5]$$

Parts of the cell surface facing the electrodes are affected. The extent of the permeabilized surface of a spherical cell, A_{perm} , is given by:

$$A_{\text{perm}} = A_{\text{tot}} (1 - E_p/E)/2 \quad [6]$$

where A_{tot} is the cell surface and E is the applied field intensity. Increasing the field strength (decreasing E_p/E) will increase the part of the cell surface, which is brought to the electropermeabilized state. This critical value of the transmembrane potential will be reached after a longer delay for the edges of the cap due to the loading time. But this

delay remains always in the μ s time scale. This will affect the mechanism of electropermeabilization only for a very short pulse duration.

These theoretical predictions were assayed on cell suspension by measuring the leakage of metabolites (ATP)²⁷ or observed at the single cell level by digitised fluorescence microscopy.^{28,29} The experimental results are in agreement with the predictions. The field strength must be larger than the threshold value E_p to induce permeabilization. The permeabilized part of the cell surface is a linear function of the reciprocal of the field intensity. Permeabilization, due to structural alterations of the membrane, remained restricted to a cap on the cell surface when short lived pulses (microseconds) are applied. The area affected by the electric field depends also on the shape (spheroid) and on the orientation of the cell with the electric field lines.²⁴ If a train of 10 pulses is applied at a frequency of 1 Hz, it is observed that long pulses (more than 1 ms) slightly larger than E_p bring a permeabilization on two caps on the cell surface, each facing one electrode.

Experimental results obtained either by monitoring conductance changes on cell suspension³⁴ or by fluorescence observation at the single cell level microscopy^{28,29} shows that the local level of permeabilization is strongly controlled by the pulse duration.^{27,28}

As an electrical current is flowing, Joule heating is taking place. The temperature of the sample increases as a linear function of the pulse duration and of the square of the field intensity. *In vitro*, this deleterious by-effect is controlled by using a low ionic content pulsing buffer to deliver a limited amount of energy. This of course cannot be controlled by that means *in vivo* but the tissue can be considered as a heat sink.

Sieving of electropemeabilization

Electropemeabilization allows a post-pulse free-like diffusion of small molecules (up to 4 kDa) whatever their chemical nature. There is a size limit for permeabilization and the process for macromolecules is described in the second part of the text. Polar small compounds cross easily the electropemeabilized membrane. But the most important feature is that this membrane organisation is long-lived in cells. Diffusion is observed during the seconds and minutes following the ms pulse. Most of the exchange takes place after the pulse.^{28,29} Resealing of the membrane defects and of the induced permeabilization is a first order process, which appears to be controlled by protein reorganisation. For a given cell, the resealing time (reciprocal of k) is a function of the pulse duration but not of the field intensity as checked by digitised videomicroscopy.²⁷ A precise analysis shows that several resealing processes are acting, two are very fast (ms, <s) while the last one remains present during several minutes at room temperature.³⁰ Resealing of membrane defects is a metabolic process under control of the energy reserves of the cell.³¹ One can take advantage of this slow resealing to deliver the successive pulses at a 1kHz frequency to reduce the duration of the treatment in ECT.³²

These observations are in agreement with a model where the target of the field is under the control of the pulse duration. Due to their internal flexibility (mainly at the level of the polar heads), phospholipids are sensitive to short pulses. Their change in configuration brings an effect on the membrane proteins. The transmembrane ionic exchange induces a secondary effect on the cell organization. When long pulses are applied, they can induce long range reorganization (an electrophoretic drift of polar membrane components) and a direct effect on more rigid dipoles such as those

associated with membrane proteins. Long pulses are not acting only on phospholipids but may affect directly the organization of membrane proteins.³³ Of course, the transmembrane exchange will be larger as the density of membrane defects will be increased.

Loading of macromolecules is a more complex mechanism, that will be described in details later.

Associated transmembrane exchange

Molecular transfer of small molecules (<4kDa) across the permeabilized area is mostly driven by the concentration difference across the membrane. Electrophoretic contribution to the transmembrane exchange during the pulse affects the loading of polar compounds.^{29,30} Free diffusion of low weight polar molecules after the pulse can be described by using the Fick equation on its electropemeabilized part.²⁷ It plays the most important contribution to the loading. This gives the following expression for a given molecule S and a cell with a radius r :

$$\Phi(S) = 2\pi r^2 P_S \Delta S X(N, T) (1 - E_p/E) \exp(-k(N, T) t) \quad [7]$$

where $\Phi(S)$ is the flow at time t after the N pulses of duration T (the delay between the pulses being short compared to t), P_S is the permeability coefficient of S across the permeabilized membrane and ΔS is the concentration gradient of S across the membrane. E_p depends on r (size). Permeabilization remains present for a longer time when cells are kept at low temperature. The cytoskeletal integrity plays also a major role.³³

Cellular responses

Reactive oxygen species (ROS) are generated at the permeabilized loci, depending

on the electric field parameters.³⁵ These ROS can affect the viability. The amount of ROS is increased with an increase in pulse duration. Long pulses may therefore be toxic for cells.

When a cell is permeabilized, a transient osmotic swelling may result leading to an entrance of water into the cell. This increase of cell volume can lead to the rupture of the membrane.^{36,37} This swelling is under the strong control of the pulse duration. Using μs pulse does not trigger swelling (with the exception of red blood cells, the so called osmotic swelling)³⁸ while a twofold increase in volume was reported when using ms pulses.

There is a loss of the bilayer membrane asymmetry of the phospholipids.³⁹

Carry-home messages on permeabilization

When cells are submitted to short lived electric field pulses, a free exchange of hydrophilic molecules takes place across the membrane. A leakage of cytosolic metabolites into the cytoplasm is obtained. Nevertheless, cell viability can be preserved under controlled electric field conditions. More drastic electric conditions affect strongly the cell viability. This effect is cell specific and some strains are weakly resistant to the electric trauma. Bringing them to a reversible permeabilized state needs a careful tuning of the electric parameters. The exchange of the hydrophilic compounds is strongly controlled by the pulse duration. Indeed the pulse duration plays a decisive role in the level of loading as it controls i) the density of permeabilized defects (X in Eq. 7) ii) the life time of these defects (k in Eq. 4).⁴⁰ Short pulses will induce few short lived defects and a very limited loading (that cannot even be detected in many conditions). A larger loading (leakage) of the cytoplasmic con-

tent will occur with long pulses. The cell viability will be preserved more when using short pulses.

Clinical applications are supported either by the loading of therapeutic compounds (bleomycin)⁵⁻⁷ or by irreversible permeabilization (IRE).⁴¹ Electrochemotherapy is obtained by a low number of successive short lived pulses (100 μs) while IRE requires a much longer treatment. A delay between pulses as short as 1 ms can be observed to reduce the pain of the patient.

DNA electrotransfer

Gene expression is obtained after applying electric pulses to a cell DNA mixture. No transfected cells were detected in absence of electric field, in absence of DNA, or when DNA was added after the pulses.^{42,43}

Electrotransfection was only detected for electric field values leading to permeabilization. Transfection threshold values were the same as the ones for cell permeabilization when pulses lasting ms were applied.⁴⁴

Events during electropulsation: Membrane –DNA interaction

Field strength is observed to have a critical role. Cell membrane must be permeabilized for plasmid-membrane interaction to occur. Plasmids interact only with the permeabilized cell surface. It is accumulated by the field associated electrophoretic drag as shown by fluorescence microscopy.⁴⁵ But no free plasmid diffusion into the cytoplasm is detected while this was proposed in older works.⁴² No plasmid membrane interaction occurs if the nucleic acids are added after electropermeabilizing cells as proposed in.^{19,38} Negatively charged DNA molecules migrate when submitted to an electric field.^{43,46} But, electrophoretic DNA accumulation by itself is not enough to

bring transmembrane transfer and gene expression whatever the pulse duration.

Under permeabilizing field conditions, the pulse duration plays a critical role in the formation of the plasmid-cell complex. The complex between the plasmid and the cell surface is detected only when the pulse duration is at least 1 ms. This suggests that the density of defects is critical in the interaction between DNA and the permeabilized membrane.

Furthermore, this interpretation is supported by the observation that the DNA content in the complex, determined by the local fluorescence emission, is under the control of the field strength and the pulse duration.⁴⁵

The reaction time of the DNA pushed against the part of the cell surface under the permeabilizing stress of the external field is increased by a longer pulse duration. This again is involved in the positive role of the pulse duration in gene electrotransfer.

This contribution of the pulse duration to the plasmid-membrane interaction has already been illustrated by a complex dependence of the gene expression.⁴³ The associated gene expression Expr is shown to obey the following equation:

$$\text{Expr} = K N T^{2.3} (1 - E_p/E) f(\text{DNA}) \quad [8]$$

as long as the cell viability is not affected to a large extent by the pulse duration.⁴⁵ All parameters are as described above, K being a constant. The dependence on the plasmid concentration (ADN) is rather complex as high levels of plasmids appear to be toxic.⁴⁷

A very recent on line videomicroscopy study showed that plasmid DNA was trapped in the electropermeabilized membrane where it forms aggregates.

The practical conclusion is that *in vitro* an effective transfer is obtained by using long pulses in order to drive the DNA towards

the permeabilized area of the membrane by electropermeabilization but with a low field strength to preserve the cell viability.^{44,48} Nevertheless, the transfection was obtained with short strong pulses in the pioneering experiments¹⁸ and with stem cells.⁴⁹

Events after electropulsation

The main conclusion of the observations during the pulse is that plasmids do not cross the membrane during that step, even if the membrane is permeabilized (for small molecules). They form complexes at the permeabilized membrane level. More than 2 s appears to be needed to get a stable DNA membrane complex after a 5 ms pulse.⁶⁶

Cell electroassociated DNA remains accessible to DNAaseI, a double-strand nucleic acid degrading enzyme, up to 60 s after the pulsation in the case of CHO cells.³ The DNA aggregates, which are anchored in the membrane after the electric field application, remain sensitive to the degrading action of the externally post pulse added nucleases, which are known not to cross the membrane

High field nanosecond field pulses cellular effect

Under classical electropulsation conditions (micro-millisecond duration, a few kV/cm magnitude), the transmembrane voltage change is only present on the plasma membrane. The interior of the cell is shielded from the external field by the plasma membrane. The electrical behaviour of the cell is different under strong HV nanosecond lasting pulses. A fast charging capacitive effect is present.⁵⁰ Two membrane capacitances, C_1 for the outer cell plasma membrane and C_2 for the inner organelle membrane, are being charged by currents from the exter-

nal voltage source. Charging of the external capacitance induces a transient voltage across the cytoplasm.⁵² It results a charging of the organelle capacitance. As the size of the organelle is very small and the conductivity of the cytoplasm is higher than that of the external buffer, the charging time of the organelle capacitor is much faster than that of the plasma membrane capacitor.⁵¹ The electric field induced transmembrane permeabilizing voltage is reached for the organelle as well for the plasma membrane.⁵² As soon as the plasma membrane is electropermeabilized, it is short circuited and only a fraction of the external field remains present on the organelles.^{50,51}

Another consequence of ultrashort pulses is the induction of an electrodeformation of the cell (electrostretching). The magnitude of this stress is high under low conductivities conditions. It brings an electrostretching of the membrane. This is supposed to contribute to the expansion step in the electropermeabilization. The induction of the force is very fast and is transiently present in the nanosecond range when a low conductivity buffer is present. The effect is not present when the buffer conductivity is close to the one of the cytoplasm.^{53,54} This stretching effect can be present only when the rise time of the electric pulse is very fast (ns). This is not the case with pulse generators routinely used nowadays. But this effect should be kept in mind with the new developments of ns HV pulse generators.

As a consequence, organelles can be electropermeabilized by nanosecond long pulses. This is indeed what is observed. Cytoplasmic stored Calcium pools are observed to be released by nanosecond pulses. Permeabilization of organelles can be used to trigger apoptosis and cell death without direct leak from the cytoplasm. This was proposed as an approach to destroy tumor cells.^{52,55-58} Preclinical studies of drug free tumor eradication were reported.^{59,60}

The nuclear envelope can be permeabilized. Therefore, a new strategy for plasmid transfer is present. In a first step, millisecond pulses are used to introduced plasmids in the cytoplasm as classically described. After a 30 min incubation, a nanosecond high strength field is applied to induce the destabilization of the nucleus membrane and to facilitate the nuclear transfer of the plasmid and its expression. A significant increase of expression can be apparently obtained.⁶¹

This new methodology is a "hot" field of investigations where encouraging results have been published. But it is not yet a mature field as "classical" electropulsation.

Conclusions

"Classical" Electropermeabilization processes can be followed from microseconds up to days. Kinetic studies of electropermeabilization led to a description in 5 steps:

1- "*Induction step*"- the field induced the membrane potential difference increase which gave local defects (may be due to kinks in the lipid chains) when it reached a critical value (about 200 mV). A mechanical stress was present with a magnitude that depends on the buffer composition. This can be detected in less than 1 nanosecond but a limit is given by the charging time of the membrane. Molecular dynamic simulation suggests that it is much faster⁶² in agreement with the nanosecond experiments (μ s to ns due to the pulse generator).

2- "*Expansion step*"- These defects expanded as long as the field was present and with a strength larger than a critical value. Again an electromechanical stress remained present. This may be due to a "coalescence" process (μ s to ms)

3- "*Stabilisation step*"- As soon as the field intensity was lower than the threshold value, that is mentioned in step 1, stabilisa-

Table 1. Operating parameters for the *in vitro* applications of electropulsation on mammalian cells

Applications	Duration	Field strength	Number of pulses
Electrochemotherapy (ECT)	100 μ s	1.3 kV/cm	8
Electrotransfection (EGT)	5 to 10 ms	0.5 to 0.8 kV/cm	8
Eradication (IRE)	300 μ s	1.5 kV/cm	3 x 10
Nanopulse eradication (nsIRE)	60 ns	12 kV/cm	200

tion processes were taking place within a few milliseconds, which brought the membrane to the permeabilized state for small molecules (ms).

4- "Resealing step"- A slow resealing was then occurring on a scale of seconds and minutes. It was a first order process. It is driven by the cellular metabolism (s to min).

5- "Memory effect "- Some changes in the membrane properties remained present on a longer time scale (hours) but the cell behaviour was finally back to normal.

Experiments showed that the mechanism of DNA transfer was different from what was observed for electropermeabilization (transfer of small molecules). Indeed, experimental results led to the conclusion that plasmids had to be present during electropulsation but crossed the electropulsed membrane in the minutes following it. No gene transfer was detected with a post-pulse DNA addition. These results were obtained on bacteria, yeast and mammalian cells.^{37,63,64}

We proposed a model in which Electrotransfection appears as a multistep process⁴³ and brought its direct experimental evidence.⁴⁵

During the pulse,

- i- electropermeabilization takes place (μ s)
- ii- plasmids are electrophoretically driven into contacts with the cell surface (ms)
- iii- a metastable complex is formed between plasmids and the localised electropermeabilized part of the cell membrane (ms).

- iv- a stable complex results (s)
- v- long after the pulse, plasmids left the complex and diffused in the cytoplasm (min)
- vi- a small fraction crossed the nuclear envelope to be expressed (h).

This interaction between plasmids and electropermeabilized membrane is strongly controlled by the pulse duration (always on the ms time scale). Additive effects of successive pulses are obtained. Only the localised part of the cell membrane brought to the permeabilized state by the external field is competent for the transfer.⁴³

Practical consequences

Electropermeabilization is one of the non-viral methods successfully used to transfer genes into living cells *in vitro* as *in vivo*. It has the main advantages of being easy to perform, fast, reproducible and safe. This approach appears promising for gene therapy and is a clinical routine for drug delivery. A careful choice of the pulse duration and delays between the successive steps of electropulsation is needed to get successful applications (Table 1).⁶⁵ This remains linked to phenomenological conclusions. Its further developments need a better understanding of the basic effects induced at the membrane, cellular and tissue levels by electrical events and the plasmid entry in the cell.

Quality of life in patients after combined modality treatment of rectal cancer: Report of a prospective phase II study

Vaneja Velenik, Irena Oblak, Franc Anderluh

Department of Radiotherapy, Institute of Oncology Ljubljana, Slovenia

Background. The literature reports are unclear whether a permanent stoma reduces the quality of life (QOL) of patients with locally advanced rectal cancer (T3-4 and/or N+). Our aim was to compare the QLQ of patients with abdominoperineal resection and with restorative surgery, treated with preoperative radiochemotherapy in a prospective phase II clinical trial.

Methods. Fifty-seven patients were irradiated to 45 Gy in 25 fractions over 5 weeks to the pelvis concomitantly with oral capecitabine 825 mg/m², twice a day, including weekends. Surgery was scheduled 4-6 weeks after the completion of the chemoradiotherapy. Four courses of chemotherapy were planned postoperatively. Patients still alive and without recurrence of the disease, with a minimum follow up of 2 years, were surveyed with two self-rating questionnaires developed by the European Organisation for Research and Treatment of Cancer (EORTC): one was cancer specific (EORTC QLQ-C30) and one was site specific (EORTC QLQ-C38).

Results. QLQ was assessed in 28 of 32 patients eligible (87.5%). The median time from surgery to filling in the questionnaires was 35 months. For all scales of EORTC QLQ-C30 and EORTC QLQ-C38, no significant differences in median scores were observed between the two groups of patients.

Conclusions. QOL did not differ in patients with abdominoperineal resection from patients with sphincter-sparing surgery.

Key words: preoperative radiochemotherapy; rectal cancer; quality of life

Introduction

The preoperative chemoirradiation has become a standard part of treatment protocols in stage II and III rectal cancer. Compared

to postoperative chemoradiotherapy, the advantage of preoperative application of chemotherapeutics and irradiation includes improved compliance, reduced toxicity and down staging of the tumour in a substantial number of patients. The latter can potentially increase the feasibility of sphincter-saving resection in low-sited tumours.¹ The impairment of anorectal, voiding and sexual function is a frequent adverse effect of the multimodality treatment. Thus, the addition of radiotherapy (RT) to surgery

improves the oncologic outcome but, potentially, adds morbidity to that associated with surgery.² A poor functional outcome after the restorative surgical technique may effect on the patient's quality of life (QOL). The construction of permanent colostomy following an abdominoperineal resection (APR) may be associated with one or more physical and psychosociological problems as well. In the past, prospective studies with rectal cancer patients have focused on the tumour response, local control, survival and treatment related toxicity as primary end-points. Although these parameters remain central in the evaluation process, there is an increasing recognition of the need to assess more systematically the impact of cancer and its treatment on the functional, psychological and social health of the individual. As MRI has become incorporated in the diagnostic procedure of rectal disease,³ the measurement of the functional outcome and QOL in rectal cancer patients, treated with preoperative radiochemotherapy and surgery has also become incorporated in clinical trials over the past decade.⁴

The aim of the present study was to assess QOL outcomes in patients treated with restorative procedures, compared with those in patients after APR by using a recommended and proven method.

Patients and methods

Patients

Between June 2004 and January 2005, fifty-seven patients with locally advanced resectable rectal cancer were treated with preoperative radiotherapy and concomitant capecitabine. Thirty-two patients, who were alive and without evidence of disease progression at a minimum follow-up of 2 years, were asked to participate in QOL

Table 1. Characteristics of patients who answered the questionnaires

study. Twenty-eight participated after having given informed consent. The characteristics of patients who answered the questionnaires are listed in Table 1.

Treatment

The details of both the patients and the treatment have been reported previously.⁵ Briefly, the prospective phase II trial has been approved by the Republic Ethic Committee. The entry criteria included: histologically verified adenocarcinoma of the rectum, clinical stage II or III (IUCC TNM classification 2002); no prior radiotherapy and/or chemotherapy; World Health Organisation (WHO) performance

status <2; age at diagnosis of 18 or older; adequate bone marrow, liver, renal and cardiac function (no history of ischemic heart disease), and written informed consent.

Radiotherapy was delivered using 15 MV photon beams and four-field box technique, once per day, 5 days weekly. The small pelvis received 45 Gy in 25 fractions over 5 weeks. Three-dimensional CT-based treatment planning was performed. The clinical target volume (CTV) was defined to cover the small pelvis from the L5-S1 interspace to 5 cm below the primary tumour. The lateral borders were 5 mm outside the true bony pelvis. The posterior margin covered the sacrum, and the anterior margin encompassed the posterior one-third to one-half of the bladder and/or vagina. An additional 1 cm in all directions was added to the CTV to obtain the planning target volume (PTV). The dose was prescribed to cover the PTV with a 95% reference isodose (95% of the ICRU point dose). Patients were treated in the prone position. They were instructed to have a full bladder during irradiation, and no devices were used to displace the small bowel out of the irradiated volume. A multileaf collimator was used for shaping the fields and for the protection of normal tissues.

Chemotherapy was administered concomitantly with radiotherapy and consisted of capecitabine administered orally at a daily dose of 1650 mg/m², divided into two equal doses given 12 hours apart. One of the doses was taken 2 hours prior to irradiation. The chemotherapy started on the first day of radiotherapy and finished on the last day of radiotherapy (including weekends).

According to the protocol, surgery was planned for 4-6 weeks after the completion of the chemoradiotherapy. Although TME was the preferred surgical technique, it was not mandatory. Abdominoperineal resection (APR) was carried out in 17 (30.9%) patients, anterior resection (AR) in 4 (7.3%)

patients, low anterior resection (LAR) in 32 (58.2%) patients, exenteration of the small pelvis in 1 (1.8%) patient and Hartmann's resection in 1 (1.8%) patient. As determined by the histopathological examination of surgical specimens, the resection was radical (R0) in 54 (98.2%) patients. A temporary colostomy was required in 32 (88.8%) patients.

Four courses of chemotherapy were planned postoperatively. It was administered in 44/55 (80%) of patients. Eighteen (40.9%) patients received adjuvant 5-Fluorouracil/Leukovorin and 26 (59.1%) patients received capecitabine.

QLQ assessment

QLQ was assessed using two validated questionnaires developed by European Organisation for Research and Treatment of Cancer (EORTC). One questionnaire assessed the cancer specific QOL (the third version of the Quality of life Questionnaire Core 30 items, i.e. QLQ-C30)⁶ and the other site - specific (colorectal) QOL (Quality of life Questionnaire Core 38 items, i.e. QLQ-C38).⁷

The QLQ-C30 is a 30-items questionnaire. It includes a total of nine multi-item scales: five functional scales (physical, role, cognitive, emotional, and social); three symptom scales (fatigue, pain, and nausea and vomiting); and a global health and quality-of-life scale. Separate six single items are included to measure gastrointestinal symptoms (diarrhoea and constipation), dyspnoea, appetite loss, sleeping disturbances and economic consequences of the disease.

The QLQ-C38 questionnaire comprises 38 questions, of which 19 are completed by all patients and the remaining by a subset of the patients (men or women; patients with or without stoma). It incorporates two functional scales (body image and sexuality) and seven symptom scales (micturition

problems induced by irradiation, chemotherapy side effects, gastrointestinal general symptoms, defecation problems, stoma-related problems, and sexual dysfunction in men and women). The remaining single items assess future perspectives and weight loss.

Both questionnaires contain questions related to the previous week. Four response categories, from 1 (not at all) to 4 (very much), are possible.

Statistical analysis

The scoring was performed according to the EORTC QLQ-C30 scoring manual.⁸ The principle of scoring was to estimate the average of the items that contributed to the scale; this was the raw score. A linear transformation was used to standardize the raw score, so that all scores ranged from 0 to 100. The higher scale score for the functional scale or the global health status/QOL represents a higher level of functioning, or higher QOL; whereas the higher level of symptoms/problems for the symptom/item scales represents a higher level of symptomatology, or dysfunction. Missing values were calculated such that if at least one-half the items from the scale had been completed, it was assumed that the missing items would have had values equal to the average of the items present.

Demographic and clinical data were calculated using descriptive statistics. Results of QOL information were expressed as means and medians. The nonparametric Mann-Whitney *U*-test was used to compare median scores of QOL scales between the two treatment groups of patients. A 5% level of statistical significance was used for variables ($P < 0.05$). Data were analyzed using SPSS for Windows (version 13.0; SPSS, Chicago, IL, USA).

We hypothesized that at least some scores of various scales would vary between

subgroups of patients in favour of patients with restorative type of surgery.

Results

Oncological outcome

Before the therapy, an abdominoperineal resection was planned in 24 out of 55 patients who had definitive surgery. After the completion of chemoradiotherapy, the sphincter-conserving surgery was successfully performed in 7 of these 24 patients. Among 31 patients in whom the sphincter-conserving surgery was planned before having had any therapy, this was not possible in two patients, which resulted in an ultimate sphincter preservation rate of 65.5% (36/55).

A local relapse has occurred in 1 (1.8%) patient and a dissemination in 13 (24.1%) out of 54 patients with a median time to progression of 23 months (range 3-23 months). Second malignancies have occurred in 2 patients. The median 2-year overall survival, disease-free survival and disease-specific survival rates were 84.2%, 72.5% and 92.4%, respectively, and local control was 98.2%.

QOL evaluation

Of 32 eligible patients from the prospective phase II trial, 28 (87.5%) completed the EORTC QLQ-C30 and QLQ-C38 questionnaires: 19 patients with sphincter conserving surgery and 9 patients with APR. Three patients refused to participate in the study and one was judged ineligible because of serious comorbidities. Surveys were completed a median of 35 (26-39) months after the surgery.

The general results of QLQ-C30 for all patients with or without stoma are given in Table 2. The global quality of life scores, representing the overall health and quality

Financial impact	29 (33)	17 (0-67)	17 (25)	0 (0-67)	0.41

of life of patients, were similar. There was no difference in medians for all other scale scores. Patients having had APR seem to have less sleep disturbances (0 versus 33; $p=0.22$) and they tended to report lower levels of role functioning (67 versus 100; $p=0.3$) and cognitive functioning (75 versus 83; $p=0.26$) than did patients having had restorative resection.

The results of QLQ-C38 for the two surgical groups are given in Table 3. No significant differences in median scores were observed between the two surgical groups for any of the scales. However, APR group of patients tended to report a lower body image score (61 versus 89; $p=0.16$). The sexual functioning score and sexual enjoyment score were very low in both groups, but in

the APR group the sexual functioning score was higher (33 versus 17; $p=0.11$).

Discussion

The abdominoperineal resection (APR) was long considered the standard treatment of tumours lying in the lower third of the rectum, providing a good local control. A more precise understanding of tumour biology and of failure patterns, has lead to the acceptance of short distal resection margins. Advances in surgical stapling and coloanal anastomoses technique have made it possible to treat many low rectal cancers by the sphincter-saving low anterior resection in preference to an APR. The survival and lo-

cal recurrence rate was not compromised.⁹

There are many other factors, which impact the decision, which surgical procedure to undertake for low-lying cancers: patient gender, preoperative sphincter function, stage of the disease, potential distal resection margin and surgeon preference. The avoidance of permanent colostomy has been used to judge the quality of the rectal cancer surgery. Although the avoidance of a permanent stoma following rectal cancer excision is regarded as a favourable outcome measure, the bowel function after the sphincter-sparing procedures may be greatly altered, resulting in faecal urgency and incontinence.¹⁰ Patients receiving preoperative radiochemotherapy for rectal cancer may develop also other unpleasant symptoms, such as micturition problems and sexual dysfunction. These symptoms, which occurred in a substantial proportion of patients, have been reported previously.¹¹ Our aim was to evaluate the effect of these

symptoms on the health-related QOL as an important endpoint.

It is difficult to evaluate the QOL after the rectal cancer surgery. For that purpose, non-cancer-specific or nonstandardized questionnaires with a different methodology for scoring were used, *i.e.* self-reported by patients or scored by physicians. Additionally, the authors provided different types of preoperative or postoperative treatment. The evaluations of QOL were mostly of retrospective nature with a different time for questionnaire administration and evaluated on small sample sizes. So, the heterogeneity in the evaluation of QOL after the rectal cancer surgery gave rise to inconsistent and conflicting findings. Any comparison between data reported by different authors might be misleading. The use of standardized questionnaires is necessary. In our study, the evaluation of health-related QOL of patients was assessed by using EORTC cancer and site specific questionnaires,

which are validated and preferred measures in recent clinical trials.

Some studies have suggested that patients with a colostomy have a poorer QOL when compared to those who had restorative resection.^{12,13} In the present study no significant differences in median scores were observed in any of the function scores of QLQ-C30 questionnaire studied (physical, role, social, emotional, cognitive functions and overall QOL) between the two groups. Our finding is in agreement with the observation reported by Allal *et al.*⁴ and Camilleri-Brennan *et al.*⁴ In a prospective study, Grumann *et al.*¹⁵ showed that following LAR patients had even a lower QOL than those who underwent APR. A recent analysis of eight studies in a Cochrane Database Systemic Review showed mixed results. Half of the studies revealed no difference with regard to QOL between APR and LAR, in one the QOL in patients with stoma was only slightly affected and others revealed that the formation of stoma significantly affected the patients QOL.¹⁶ The similarities in QOL in stoma and non-stoma patients may be due to the adaptation and the phenomenon of "response shift",¹⁷ in which patients who have survived life-threatening disease seem to have new internal standards and, thereby, often report good QOL. Even patients who have undergone pelvic exenteration report having good QOL.¹⁸ In agreement with other authors, we found that APR was associated with a lower perception of body image (feeling less attractive) than LAR.

Defecation-related problems, such as urgency, incontinence and incomplete bowel emptying, are well-known side effects of sphincter-preserving surgery.¹¹ Interestingly, the assessment of gastrointestinal problems on the QLQ-C38 and constipation on the QLQ-C30 showed similarities in the two groups. Camilleri-Brennan *et al.* found that patients who had sphincter

saving resection had more problems with constipation.⁴ Scores for stoma-related problems in both studies were comparable low, probably due to better stoma care. Standardized training by the specialized nurse is performed in every stoma patient in our department. That might lead to a better perception of QOL in our study.¹⁹

While most of the studies have suggested that the sexual function was impaired in patients receiving permanent stomas,^{15,20,21} in present study, no difference in this dimension of the QLQ-C38 was revealed. Unexpected, the sexual functioning score tended to be higher in patients with APR than in patients with LAR, although the difference was not significant. Because of a small sample size and older age of our patients than in other studies, no valid conclusion can be made regarding this issue. Urinary problems were more frequently encountered after APR than after LAR. These differences are probably surgeon dependent.

The present study is limited by a lack of control measurements before the treatment. In addition, the number of evaluated patients was small, as only patients without evidence of disease treated in one clinical trial were surveyed. So a lack of statistical power might also be relevant. To obtain a large, unselected patient sample, we started to evaluate the QOL of all patients with rectal cancer, treated with preoperative radiochemotherapy, prospectively: before preoperative treatment, 1 year and 3 years after the operation.

In conclusion, consequences of the multimodality treatment of rectal cancer have an important bearing on QOL. Patients after the combined modality treatment with restorative surgical procedures do not necessarily have a better QOL, mainly due to the impairment of the bowel function. In addition to traditional endpoints, such a disease control and survival, assessing restrictions

in QOL are necessary to provide a comprehensive understanding of the outcome of the combined modality treatment.

Management of cutaneous side effects of cetuximab therapy with vitamin K1 crème

Janja Ocvirk and Martina Rebersek

Department of Medical Oncology, Institute of Oncology Ljubljana, Ljubljana, Slovenia

Background. Cetuximab is a chimeric human-murine monoclonal antibody against the epidermal growth factor receptor (EGFR). It has shown activities against multiple malignancies in clinical trials. EGFR-inhibitors often cause skin toxicity, most frequently acneiform eruption. Xerosis, eczema, fissures, teleangiectasias, nail changes and paronychia can be seen in some cases, rarely hyperpigmentation. The management of the skin toxicity helps patients to overcome cetuximab-associated skin toxicity and is of great importance for patients' compliance. It is generally manageable with standard topical or systemic antibiotics and anti-inflammatory agents. The education of patients prior to beginning the therapy and proactive intervention at the first signs of skin toxicity are keys to the successful management. The aim of our study was to investigate cutaneous side-effects of the treatment with cetuximab and to determine the efficacy of vitamin K1 crème.

Methods. From September 2006 to August 2007 30 patients with metastatic colorectal cancer were treated with cetuximab in combination with chemotherapy and suffered from acne-like rash. They were followed at least 3 months, once per week. Skin care was taken with crème with urea and 0.1% K1 vitamin (Reconval K1[®]) topically starting after first documented cutaneous toxicity, and was evaluated according to NCI CTCAE, ver.3.

Results. Of 30 patients 6 had grade 3 rash, 18 patients grade 2 and 6 patients grade 1. Reconval K1[®] was used twice daily. In all patients we observed the improvement of cutaneous toxicity. The median improvement was 8 days and 18 days to observe down-staging in rash at least for 1 grade. In only 3 of 6 patients with grade 3 toxicity the reduction of cetuximab dose was needed. In historical controls in all patients with grade 3 the reduction of cetuximab dose was recommended and performed. No dose reduction or delay of treatment was needed in group of patients with grade 1 and 2 cutaneous toxicity. We didn't observe any local or systemic toxicity of topical use of Reconval K1[®].

Conclusions. To our knowledge this is the first documented effect of topical use of K1 vitamin crème for reducing cetuximab induced cutaneous toxicity in patients with metastatic colorectal cancer. We conclude that Reconval K1[®] is useful in skin care in patients treated with cetuximab. Further studies are needed to evaluate the impact on response rate of cetuximab and quality of life.

Key words: cetuximab; cutaneous side-effects; vitamin K1 crème; colorectal cancer

Introduction

Cetuximab is a chimeric immunoglobulin G1 (IgG1) monoclonal antibody that binds to the extracellular domain of epidermal growth factor receptor (EGFR) with high specificity and a higher affinity than that of epidermal growth factors, thus blocking ligand-induced phosphorylation of EGFR. The affinity is approximately 5 to 10-fold higher than that of endogenous ligands.^{1,2}

EGFR (c-erbB1 or HER1) is a member of the ErbB family of tyrosine kinase receptors. EGFR is a 170-kd cell surface protein composed of 3 regions: an extracellular ligand-binding domain, a hydrophobic transmembrane domain, and an intracellular domain with adenosine triphosphate (ATP)-dependent tyrosine kinase activity.³ EGFR signalling pathways are involved in the control of cell survival, cell cycle progression, angiogenesis, cell migration and cellular invasion/metastasis.⁴

EGFR is found to be overexpressed in many of human tumours: colorectal, gastric, oesophageal, head and neck, lung, breast and prostate cancer, as well as glioblastoma, bladder and ovarian carcinoma.^{2,5}

Binding of the antibody to EGFR prevents the stimulation of the receptor by endogenous ligands and results in inhibition of cell proliferation, enhanced apoptosis, and reduced angiogenesis, invasiveness and metastasizing. Binding of cetuximab to the receptor also results in internalization of the antibody-receptor complex which leads to an overall downregulation of EGFR expression.⁶ Preclinical studies have demonstrated that cetuximab reduces the resistance to chemotherapy and radiotherapy of human tumour cell lines *in vitro* and of nude mice bearing xenografts of human tumours. In clinical and preclinical studies, cetuximab has been shown to induce a response to treatment when used

in combination with chemotherapy in the patients previously refractory to chemotherapy.⁶

Clinical efficacy of cetuximab

Cetuximab in combination with irinotecan and oxaliplatin is approved for the treatment of patients with epidermal growth factor receptor (EGFR)-expression in metastatic colorectal cancer. In combination with radiation therapy, it is indicated for the treatment of patients with locally advanced squamous cell cancer of the head and neck (SCCHN).⁴

Metastatic colorectal cancer (CRC)

The approval of cetuximab followed the positive results of BOND trial; the combination of cetuximab plus irinotecan induced a response rate of 23% in the patients with irinotecan refractory EGFR-positive metastatic CRC and tumour stabilization in 33% of patients. The response rate after cetuximab alone in this trial was 11%.⁷

The data from the large study (MABEL) confirmed the activity of cetuximab in heavily pre-treated patients. The overall response rate was 20%, the disease control rate was 45% and the survival estimate was at that time 9.2 months.⁸

The EPIC study investigated the overall survival of the second-line irinotecan versus irinotecan plus cetuximab in metastatic CRC patients after the progression or intolerance of the first-line oxaliplatin based regimen. The addition of cetuximab to irinotecan led to a significant increase in RR (16.4 *vs* 4.2), a significant increase in disease control (61.4 *vs* 45.8), and a 30% reduction in the risk of disease progression.⁹

Cetuximab was used in the first-line therapy in several small trials and showed promising results.² There are also trials showing the effectiveness of cetuximab in

the first-line treatment of mCRC: a phase III study (CRYSTAL trial) comparing standard FOLFIRI alone with cetuximab in combination with FOLFIRI proved the effectiveness of cetuximab. With the use of cetuximab, the median progression-free survival was significantly longer (8.9 months *vs* 8 month), and the response rate increased (46.9% *vs* 38.7%), thereby reducing the relative risk of progression by approximately 15%.¹⁰

The large phase II study comparing cetuximab plus FOLFOX-4 with FOLFOX-4 alone in the first-line treatment (OPUS trial) showed that the combination was effective and safe. The overall response rate increased by 10%.¹¹

Cetuximab is also effective in combination with the angiogenesis inhibitor bevacizumab. The phase II trial (BOND-2 study) showed that the combination therapy with cetuximab, bevacizumab and irinotecan, compared to cetuximab and bevacizumab

alone, improved the efficacy. After irinotecan failure, this combination increased the response rate and prolonged the time to progression (response rate was 37% *vs* 23% and median time to progression 7.9 months *vs* 5.6 months).¹²

The combination therapy with cetuximab after the failure of the conventional therapy increases resectability rates without increasing operative mortality or liver injury. Adam and colleagues showed that 7% of patients treated with cetuximab after the failure of the conventional therapy experienced a treatment response that allowed curative hepatectomy. These patients were unresectable after two or more lines of conventional treatment and prior to the initiation of the treatment with cetuximab.¹³

The results from phase I study¹⁴ and phase II study showed that cetuximab could be safely administered every second week.¹⁵

Squamous cell carcinoma of the head and neck (SCCHN)

Cetuximab plus radiotherapy show a significant efficacy benefit over radiotherapy alone in the treatment of locally advanced SCCHN. The risk of the locoregional progression was 32% lower with the use of cetuximab plus radiotherapy than with radiotherapy alone. Cetuximab plus radiotherapy also demonstrated a significant improvement in the median overall survival versus radiotherapy alone. Also the risk of death was 26% lower with the use of cetuximab plus radiotherapy compared to radiotherapy alone.¹⁶

Cetuximab was investigated in the second-line and first-line settings for the patients with recurrent/metastatic SCCHN following the failure of surgery or radiotherapy. In the phase III randomized comparison of cisplatin plus cetuximab or cisplatin plus placebo, the addition of cetuximab to cisplatin increased the response rate to 26% and 10%, respectively, and was also associated with the trend towards a prolonged median overall survival (9.2 vs 8.0 months).¹⁷

The phase I study showed that the addition of cetuximab to a platinum/5-FU combination in the treatment of patients with recurrent and/or metastatic SCCHN was active and well tolerated in the first-line settings.¹⁸

Cetuximab was also effective in nasopharyngeal carcinoma: the combination of cetuximab plus carboplatin showed an important clinical benefit in the patients with recurrent and/or metastatic nasopharyngeal carcinoma failing chemotherapy with an overall response rate of 12% and median overall survival of 7.6 months.¹⁹

Other indications

In the phase I and II studies, it was shown that the combination of capecitabine plus

cetuximab together with radiotherapy, as well as capecitabine, oxaliplatin plus cetuximab together with radiotherapy could be feasible and safe regimens for rectal cancer.²

Other phase II and III studies showed a significant response to treatment in variable proportions of patients with non-small cell lung cancer (NSCLC) when cetuximab was used as the first- or second-line in combination with chemotherapy.⁶

Safety profile and side effects

Cetuximab is well-tolerated in cancer patients both as a single agent and in combination with other anti-cancer agents or radiation. Skin reactions may develop in more than 80% of patients and mainly present as acne-like rash and/or, less frequently, as pruritus, dry skin, desquamation, hypertrichosis, or nail disorders (e.g. paronychia). Approximately 15% of the skin reactions are severe, including single cases of skin necrosis. The majority of skin reactions develop within the first three weeks of therapy. They generally resolve, without sequelae, over the course of the following weeks and months even when the treatment is continued.^{2,7,20}

In combination with irinotecan, additional reported undesirable effects were those related to irinotecan (such as diarrhoea, nausea, vomiting, mucositis, stomatitis, fever, leukopenia, alopecia).

In combination with the local radiation therapy of the head and neck area, additional undesirable effects were those typical of the radiation therapy (such as mucositis, radiation dermatitis, dysphagia or leucopenia, mainly presenting as lymphocytopenia).⁴

Anaphylactic hypersensitivity reactions, characterized by a rapid onset of airway obstruction, urticaria, and hypotension, occurred in 3% of patients. Approximately

90% of the reactions developed with the first cetuximab infusion, despite premedication with antihistamines.

Other serious adverse events during cetuximab monotherapy, with the incidence of 5% or less, included interstitial lung disease, fever, sepsis, kidney failure, pulmonary embolus, dehydration, and diarrhoea.⁴ Progressively decreasing serum magnesium levels which, in some patients, developed into severe hypomagnesaemia, were also noted.²¹

The EGFR is important for the normal skin development and the function.²² In normal adult human epidermis, EGFR is strongly expressed in keratinocytes, in the sebaceous glands, and also in the epithelium of hair follicles. The expression is higher in the basal layer of the epidermis and in the outer root sheath of hair follicles, where the keratinocytes are proliferating and are undifferentiated. After the therapy with EGFR inhibitor, histopathological findings of the skin showed a thinner and more compact stratum corneum as well as prominent keratin plugs.²³ Thus, blocking the EGFR pathway leads to a unique group of skin reactions dominated by an acne-like eruptions, eczema, xerosis, changes of the hair and nails.

Vitamin K is activator EGFR pathway. The use of vitamin K crème can reduce skin toxicity caused by EGFR inhibitors.²⁴ The aim of our study was to determine the efficacy of vitamin K1 crème.

Patients and methods

The treatment of metastatic colorectal cancer with cetuximab after the failure of the treatment with irinotecan was first performed in Slovenia in 2005. During the period from September 2006 to August 2007, thirty patients with metastatic colorectal cancer were treated with cetuximab in com-

bination with chemotherapy and suffered from acne-like rash.

The patients with the typical acneiform rash skin reactions were included. They occurred from the sixth day after the first application of cetuximab to 14 days at the latest. They were followed once per week at least 3 months. For the clinical improvement was relevant the improvement of skin adverse reactions at each control. Skin care was taken with crème with urea and 0.1% K1 vitamin (Reconval K1[®]) topically twice per day starting after the first documented cutaneous toxicity. It was classified according to the National Cancer Institute Common Toxicity Criteria, Version 3.0 (NCI CTC v 3.0 (Table 1).²⁵

Erbixux was administered at a loading dose of 400 mg/m² infused over 2 hours, followed by a weekly dose of 250 mg/m² infused over 1 hour. The patients were premedicated with a histamine₁ antagonist with or without corticosteroids.

Results

The treatment with cetuximab showed a great efficacy with the evident skin toxicity. The most common side effect seen with cetuximab was an acneiform skin rash. The following skin reactions were also observed: hair and nail changes, rhagades, paronychia, trichomegalia, and uveitis.

Acneiform rash skin reactions

Acneiform eruptions were more or less confined to the seborrhoea areas which are rich in sebaceous glands (face, neck, scalp, shoulders, upper trunk and chest in V-shaped patterns) (Figures 1-3). Occasionally, they affected lower parts of the back and abdomen, but rarely arms and legs.

Six out of 30 patients experienced grade 3, 18 patients grade 2, and 6 patients grade

Figure 1. Typical acneiform eruption caused by EGFR inhibitors.

Figure 2. Typical acneiform eruption caused by EGFR inhibitors.

1 acneiform rash skin reaction at the time we started to manage skin rash.

Acneiform eruptions compared to the acne vulgaris are different and are appearing on the changed skin which is very dry and

Figure 3. Typical acneiform eruption caused by EGFR inhibitors.

disposed to cracks. The skin lesions consist of follicular papules, which may evolve into pustules and possibly dry out with the formation of yellow crusts. Skin lesions can be accompanied by pruritus and xerosis. The aetiology of acneiform eruptions differs from that of acne vulgaris; so, the treatment generally used for acne vulgaris is not helpful and we do not advise it (i.e. the treatment with benzoyl peroxide).

In all patients skin care with K1 crème twice per day was performed. For grade 2 acneiform eruptions, topical antibiotic preparations, mostly clindamycin (1%) and erythromycin, are used according to the antibiograms and experiences, concomitantly with vitamin K1 crème, when pustules were observed. We used systemic antibiotics in 4

Figure 4a. Acneiform rash before treatment with vitamin K1 crème.

Figure 4b. The skin after 1 week of using vitamin K1 crème.

Figure 5a. Acneiform rash before treatment with vitamin K1 crème.

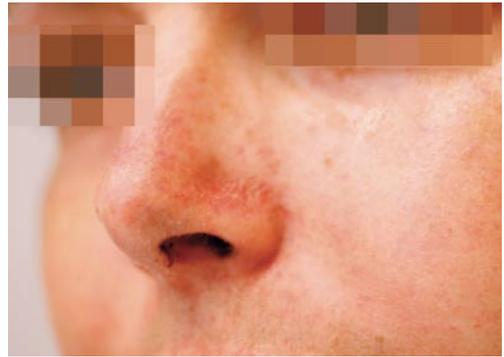

Figure 5b. The skin after 1 week of using vitamin K1 crème.

patients with G3 skin rash and topical antibiotics in 2 patients with G3 and 5 patients with G2 skin rash.

Median observed time for the improvement of skin toxicity was 8 days, but according to patients' report it was even shorter. We also recorded lowering of grade of skin rash. Median time for the improvement of skin rash of all grades was 18 days.

The results of the improvement of skin rash are presented in figures (Figures 4-7).

In case of grade 3 reaction, the treatment with cetuximab should be discontinued until the reactions resolve according to SmPC of drug. The treatment can be restarted at a lower dose. We discontinued the treatment

in only 3 patients with G3 skin rash; no case of grade 4 skin rash was reported.

Other less common reactions are nail changes (paronychia), hair modifications, xeroses trichomegalia, dry itchy skin, rhagades, uveitis and conjunctivitis, telangiectasias, hyperpigmentation, fissures in genital and anal region.

In a group of patients, where we used vitamin K1 crème, 3 and 6 months after the treatment we did not observe any xeroderma or telangiectasias, even they are frequently noticed in the cetuximab treatment; especially we observed them in patients before using vitamin K1 crème.

Figure 6b. The skin after 1 week of using vitamin K1 crème.

Figure 7a. Acneiform rash before treatment with vitamin K1 crème.

Discussion

Cetuximab is a monoclonal antibody which is registered for the treatment of metastatic colorectal cancer, head and neck cancers and lately also in the treatment of NSCLC. By blocking EGFR inhibits the proliferation of different types of tumour cells, as well as normal cells expressing EGFR, which are in skin, intestinal mucus and liver cells. The overexpression of EGFR in the epidermis, sweat glands, hair follicles and endothelium cells is reflected as an adverse reaction on the skin, mucus membranes, hair and nails.^{20,26}

Skin toxicities are especially acneiform eruption, xerosis, fissures of palms and foot, paronychia and changes in hair growth. Aetiology and signs of skin reactions of patients in our study were very similar as described in many articles.²⁷⁻²⁹

Adverse events are related to the dose and are more intensive at high dose; by the lowering of the dose, the intensity of adverse events decreases, too. The correlation between the extent and/or severity of the acneiform eruption and anti-tumour efficacy of cetuximab, which was reported in literature, was observed also in our patients.²⁰

Therapeutic methods for the management of skin adverse effects observed in the

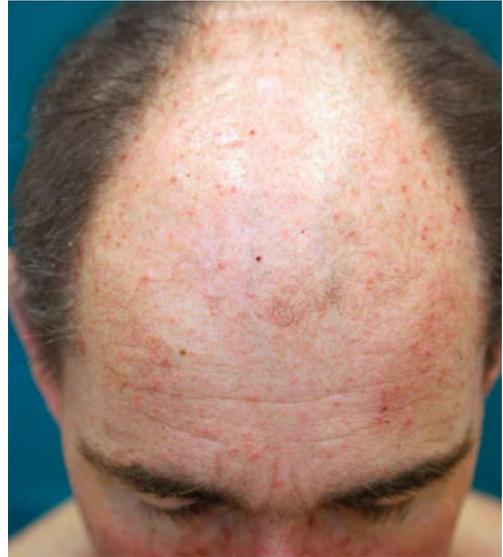

Figure 7b. The skin after 1 week of using vitamin K1 crème.

treatment with cetuximab are not standardized because there are no effective products to treat them and, above all, because published data are very contradictory.

In all patients with G1 acneiform rash we used only vitamin K1 crème. In patients with super-infections of skin presented as pustules, we used also topic or systemic antibiotics according to clinical references and the extent of infection (G2 and G3 side effects). We also used 1% topic antibiotic clindamicyn in 5 of 18 patients with G2 skin toxicity, namely, pustules and 2 with G3 skin toxicity. We often decided for the use of systemic antibiotic in such cases according to previous experiences. According to our experiences, we advise not to use benzoyl peroxide for the management of acneiform eruptions, as well as not to use corticosteroids.

For the patients who have grade 1 acneiform eruptions, the treatment with vitamin K1 crème alone was enough to manage skin toxicity. For the patients with grade 2 skin eruptions, the addition of topical antibiotics to the already mentioned therapy is recom-

mended for those with pustules; especially clindamycin is clinically proved and according to its antibiogram considered to be the most effective antibiotic. The appropriate treatment of the patients with grade 3 skin reactions is systemic treatment with antibiotic clindamycin and topically with vitamin K1 crème.

Conclusions

It is very important to recognize timely and accurately the skin adverse effects of EGFR inhibitors and to treat them promptly in order to assure a better quality of life to the patients during the treatment. In addition to traditional endpoints, such as disease control and survival, the quality of life became more and more important.^{27,30} The proper management of skin reactions enables the longer treatment with cetuximab, without the dose reduction or drug discontinuation. The continuous treatment assures effective treatment, better response to treatment, and longer survival of patients, which is the most important goal to be achieved.

Patients have to be encouraged to follow physician's advice regarding the treatment of dermatological side effects. The appropriate treatment of side effects allows the patients to continue receiving the therapy without dose reduction or drug discontinuation and to have better outcome of the treatment.

The study performed at our clinic is the first documented effect of topical use of K1 vitamin crème for reducing cetuximab induced cutaneous toxicity in patients with metastatic colorectal cancer. We conclude that Reconval K1[®] is useful in skin care in patients treated with cetuximab. Further studies are needed to evaluate the impact on the response rate of cetuximab and quality of life.

Background. Solitary metastasis of renal cell carcinoma in the pituitary gland is extremely rare and only in 7% of cases it is symptomatic.

Case report. We report the case of a 52 year old man presenting with visual disturbance and headache after three years of treatment due to the metastatic renal cell carcinoma. Magnetic resonance imaging (MRI) showed tumour mass in suprasellar region compressing optic chiasm with no other brain metastatic lesions. The trans-sphenoidal reduction of the tumour was performed. Pathology and immunohistology revealed metastasis of clear cell renal carcinoma.

Conclusions. This is the 25th case of symptomatic pituitary metastases of renal cell carcinoma reported in literature.

Key words: pituitary gland; renal cell carcinoma; metastasis

Introduction

Renal cell carcinoma is the most common primary tumour of the kidney accounting 1 - 3% of all adult malignancies.¹ Although brain is the fourth most common site of metastasis after lung, bone and liver with approximately 5%¹, solitary metastasis of renal cell carcinoma in the pituitary gland

is extremely rare.¹⁻⁶ The frequency of pituitary metastases from systemic malignant tumours ranged from 1% to 25% at autopsy.⁷ Only 7% of pituitary metastases are symptomatic.² Pituitary metastases occur usually in patients with highly disseminated disease. Breast and lung cancer are the most common diseases that metastasize to the pituitary gland.^{2,6}

Case report

We present the case of a patient diagnosed with a pituitary gland metastatic renal cell carcinoma after three years of treatment due

Figure 1a. Tumour mass in suprasellar region presented by magnetic resonance imaging (MRI), sagittal image.

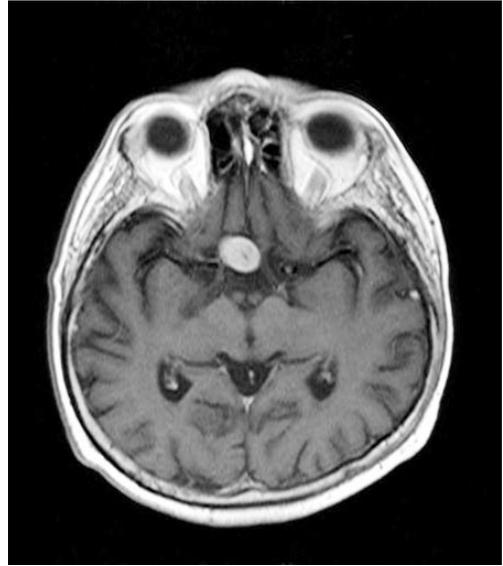

Figure 1b. Tumour mass in suprasellar region presented by magnetic resonance imaging (MRI), axial image.

to the metastatic disease. In August 2003, a 49 year old man presented with tumour of the lower part of the left kidney. Left nephrectomy was performed. Pathology confirmed clear cell carcinoma, tumour stage T3bN0M0. During his first postoperative visit to the oncological department multiple bilateral lung metastases smaller than 1 cm in diameter were found along with osteolysis of the posterior part of the fourth right rib. Patient ECOG score was 0. Since interferon and interleukin-2 were not registered for the treatment of metastatic renal cell carcinoma in Croatia, his treatment was started with chemotherapy – vinblastin 6 mg/m² every two weeks from December 2003 until June 2004.

Control examinations performed during the treatment revealed a stable disease. However, on control computed tomography (CT) in September 2004 the progression of the fourth posterior rib lesion measuring now 3.5 x 6.8 cm in diameter with protrusion in intratoracic space was found. Lung metastatic disease was stable. There was no sign

of other metastatic site. The palliative radiotherapy treatment to the progressed lesion of the fourth posterior rib was performed; dose 30 Gy in 10 fractions. The second line chemotherapy was lomustin (CCNU) 160 mg every 5 weeks, 7 cycles, from October 2004 until May 2005.

CT scan done in May 2005 revealed the progression of lung metastases *i.e.* enlargement in size and number of lung lesions. On the contrary, the lesion of the fourth rib was smaller than on the previous CT scan. Since June 2005 until September 2005 the patient was treated with 5-fluorouracil (5-FU) once a week and with an interferon A 2α 3 mil IU sc. three times a week (purchased by the patient). Due to the fatigue of the patient and enlargement of the fourth rib lesion, along with stable disease of other metastatic lung lesions, it was decided to perform reirradiation to enlarged lesion, total dose 30 Gy in 10 fractions. From December 2005 until April 2006, 5-FU and interferon A 2α therapy was continued. Due to the progression of the lung lesions from April 2006 un-

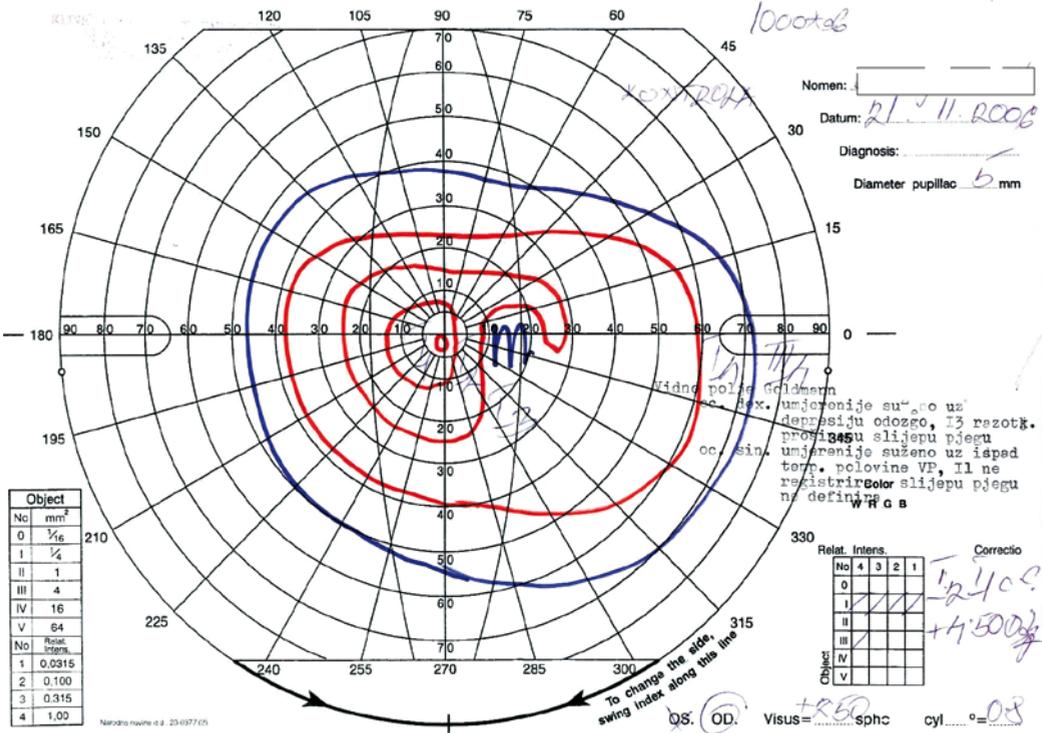

Figure 2a. Disturbances in visual function presented by Goldmann test, right eye.

til August 2006 the patient was treated with gemcitabin 600 mg/m², days 1 and 8, every 28 days (purchased by the patient).

In August 2006 vision disturbances and headache had been first reported. Magnetic resonance imaging (MRI) showed tumour mass in suprasellar region 30 x 13 mm in diameter compressing optic chiasm. A radiological examination did not demonstrate other possible brain metastatic lesions. Based on the radiological imaging it was difficult to differentiate pituitary macroadenoma, meningioma and metastasis of tumour (Figures 1a, 1b).

Since visual function deteriorated progressively, a trans-sphenoidal surgery was performed. Pathology and imunohistology revealed metastasis of clear cell renal carcinoma.

The visual function was quickly improved but Goldmann test (Figures 2a, 2b) showed still disturbances in the visual function. Endocrinological findings were almost consistent with panhypopituitarism: T4 = 80.8 nml/L (normal range 70 - 165), TSH < 0.05 mIU/L (0.40 - 4.2), testosterone < 0.03 nmol/L (3 - 22, for > 50 yrs), SHBG 7 nmol/L (15 -100), cortisol = 13 nmol/L (138 - 690), aldosteron = 879 pmol/L (20 - 410). A replacement hormone therapy was introduced to the patient.

Postoperative control MRI after two months showed residual tumour 20x13x12 mm in diameter but now along with multiple brain metastases. The palliative brain photon beam radiotherapy was performed, total dose 30 Gy in 10 fractions. CT scan of thorax and abdomen revealed the progression of the lung metastases and the occur-

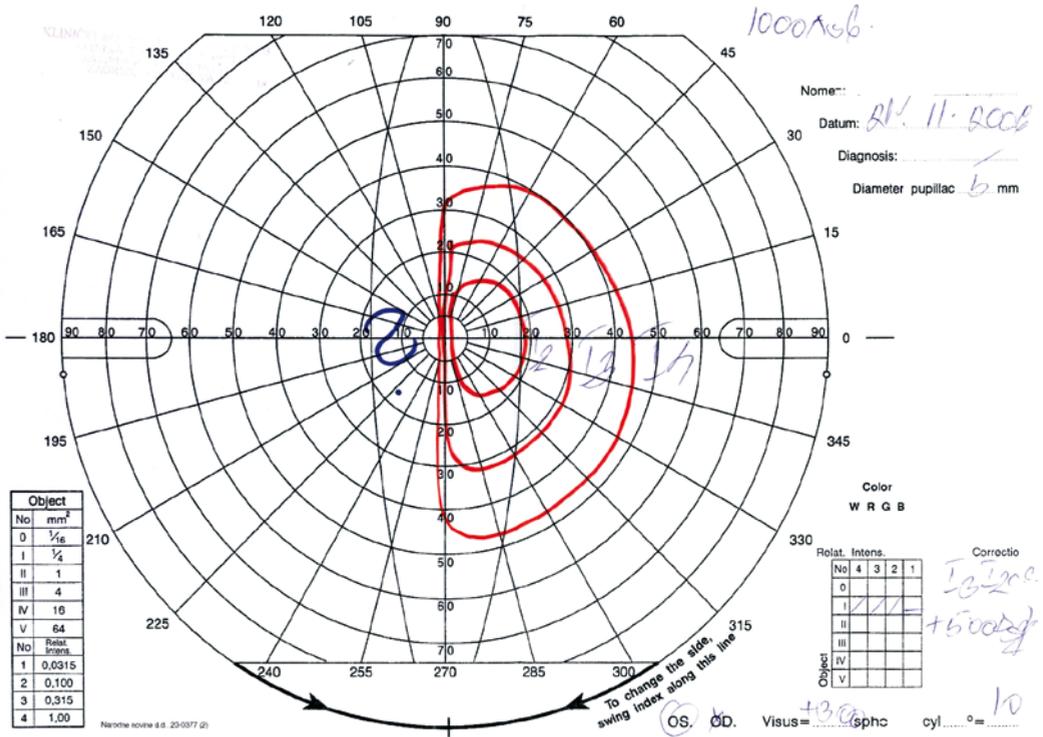

Figure 2b. Disturbances in visual function presented by Goldmann test, left eye.

rence of new bone metastases. Surprisingly, the patient was without respiratory disturbances but he reported fatigue. His general appearance was Cushingoidal. He died ten months after the operation of the pituitary gland.

Discussion

Up to our knowledge only 24 cases of symptomatic pituitary metastasis of renal cell carcinoma has been reported in the literature (Table 1). Only six of them were female, while 18 were men. The majority *i.e.* 19 patients presented with hypopituitarism, while 17 patients presented with visual field defect like our patient. Our patient has not experienced symptoms of *diabetes insipidus* which is reported to be

more frequent in pituitary metastasis than in pituitary adenomas.^{7,21} It is very difficult to differentiate pituitary metastasis from adenoma based on radiological and clinical findings.^{2,3,10,12,22} But Liu *et al.*⁷ found out that the strong enhancement of the tumour and the strong bone destruction without marked sellar enlargement are characteristic radiological features of pituitary metastasis. Fassett *et al.*² stated that thickening of the pituitary stalk, invasion of the cavernous sinus and sclerosis of the surrounding *sella turcica* could indicate pituitary metastasis. Tumour invasiveness usually makes the resection difficult. There was no significant survival benefit in surgical series.² The treatment of pituitary metastasis is multimodal, consisting of surgery, radiotherapy and chemotherapy. The long-term benefit of postoperative radiotherapy is not known

due to the rarity of such cases. The applied dose ranged in the literature from 9 to 60 Gy, with median dose 36 Gy.⁶ Our patient was treated with 30 Gy in ten fractions due to the occurrence of brain metastases although first it was intended to apply a higher dose. Stereotactic radiotherapy can be beneficial in sparing the optic nerves. The primary aim of treating pituitary metastasis is to improve the quality of life through symptomatic relief and to prevent the neurological deterioration.

The overall median length of the patient's survival after the diagnosis of pituitary metastasis is only 180 days.⁶ However, the paper recently published by Gopan *et al.*²⁰ reported the overall survival ranging from 6 to 46 months from the initial diagnosis of pituitary metastasis. This can be explained by the application of new chemotherapeutic agents like sorafenib and sunitinib. Stereotactic radiotherapy with or without whole brain radiotherapy was performed in all five reported patients.

In our case, whole brain radiotherapy was performed due to the brain dissemination. Sorafenib and sunitinib were not registered for the treatment of metastatic renal cell carcinoma in our country at the time.

Symptomatic pituitary metastasis of renal cell carcinoma is a rare case, occurring usually in highly disseminated renal cell carcinoma. Palliative surgery and radiotherapy treatment can contribute essentially to the improvement of the quality of life of such patients.

A phantom to assess the accuracy of tumor delineation using MRSI

Amr A. Heikal, Keith Wachowicz, Steven D. Thomas, Biagio Gino Fallone

Department of Medical Physics, Cross Cancer Institute; Departments of Oncology and Physics, University of Alberta, Edmonton, Alberta, Canada

Background. Studies have demonstrated that magnetic resonance spectroscopic imaging (MRSI) can detect regions of abnormal activity (tumor) that would not have been covered using conventional imaging and contouring methods. With increased interest in MRSI it is important that its accuracy in tumor delineation be investigated. While some effort has been made to design phantoms to examine the performance of MRSI sequences, most phantoms rely on using traditional glass or acrylic as the phantom building material.

Material and methods. In this work, a gel-based detail phantom has been developed to assess the ability of the spectroscopic imaging sequences to accurately represent the geometry of tumors. The gel-based phantom is used as an alternative to conventional acrylic or glass based phantoms for use with MRSI.

Results. Gel-based phantoms have the advantage of having a magnetic susceptibility close to that of water. In addition, we demonstrate the benefits of having no finite wall thickness separating phantom compartments. The utility of the phantom was illustrated in comparisons between different MRSI sequences of the same nominal resolution as well as different filtering parameters.

Conclusions. Due to their ease of construction and the reduced artifacts, gel phantoms are a reliable tool for assessing the performance of MRSI sequences.

Key words: MR spectroscopic imaging; tumor; phantoms; brain; 3 T

Introduction

The advantages that spectroscopic imaging can offer cancer therapy are significant. By measuring different metabolite levels – effectively a means of non-invasive biopsy

– magnetic resonance spectroscopic imaging (MRSI) can detect tissue abnormalities that may not yet be visible in conventional MRI. Pirzkall *et al.* and Pallud *et al.* have shown that tumor extent as shown by MRSI may differ greatly from the extent shown on conventional MRI scans.^{1,2} Moreover, Walecki *et al.* have shown that MRSI may help in identifying patients who have a high risk of recurrence.³ This has led to an increase in interest in incorporating MRSI into treatment planning by adding a biological target volume in the contouring process. More recently, several methods of

tumor identification and registration techniques have been used to integrate MRSI results into the radiotherapy process.^{4,5} Such studies have demonstrated that MRSI can detect regions of abnormal activity (tumor) that would not have been covered using conventional imaging and contouring methods.⁵ As such, the delineation of the tumor volume in treatment plans for radiotherapy has changed when MRSI metabolite information was considered.

In the midst of the move to improve the spatial resolution of MRSI, it is important to remember that the ability to properly visualize detailed tumor boundaries is influenced by many imaging and processing parameters, not just the nominal resolution of the scan. Also, with the increased importance of spatial definition of the tumor site for radiotherapy, it is of great importance to have a method of evaluating the accuracy of the boundaries derived from an MRSI sequence under development for use in radiotherapy planning.

While some effort has been made to design phantoms to examine the performance of MRSI sequences; most phantoms have relied on using traditional glass or acrylic as the phantom building material.^{6,7} Detail phantoms utilizing acrylic or glass containers are vulnerable to susceptibility artifacts arising from the interface of the compartment wall material and the solution used to fill the phantom.⁸ Those artifacts are more pronounced in high-detail and irregularly shaped phantoms.

Moreover, detail phantoms rely on a sharply defined boundary between two regions of the phantom. The amount of detail an imaging sequence can reproduce is measured by how accurately it can reproduce that boundary. Having a finite wall containing no metabolites causes a pronounced partial volume artifact in the spectral data. Those artifacts enhance that boundary in a way that is not representa-

tive of a human brain. This is demonstrated in the results and discussion section.

In this work, a gel-based detail phantom has been developed to assess the ability of the spectroscopic imaging sequences to accurately represent the detailed geometry of tumors. The gel-based phantom is used as an alternative to conventional acrylic or glass based phantoms for use with MRSI because it avoids susceptibility and compartment wall-related partial volume artifacts. The use of the phantom is demonstrated by comparing the performance of three MRSI sequences.

Material and methods

Gelatin detail phantom design

A phantom designed to simulate tumors was constructed using 5% by weight porcine gel containing clinically relevant concentrations of choline chloride (3 mM) and creatine hydrate (10 mM).⁹ A cast acrylic wedge (base: 3.8 cm, height: 9 cm, width: 3.8 cm) was inserted in the liquid gel and later removed when the gel hardened. The void left by the wedge was filled with a solution containing elevated levels of choline chloride (10 mM), and the same concentration of creatine as in the background (Figure 1). The higher concentration of choline inside

Figure 1. A photograph and a T2 weighted transverse image of the porcine gel detail phantom.

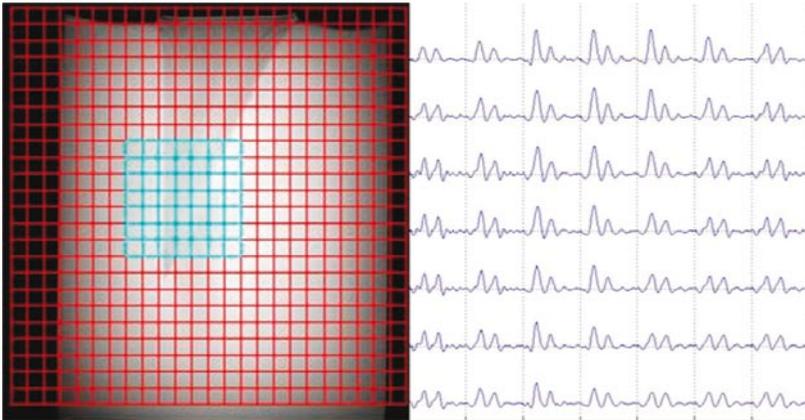

Figure 2. The spectroscopic imaging pixel locations overlaid on the T2 weighted image of the phantom. The spectra on the right correspond to the highlighted pixels. The peaks shown are Choline (left) and Creatine (right). The change in the Choline concentration inside the wedge-shaped compartment is clearly noticeable on the spectra.

the wedge-shaped void was used to simulate the presence of a malignancy.

Comparison of MRSI sequences

The phantom is designed to assess the ability of the spectroscopic imaging sequences to accurately represent the detailed geometry of tumors. The utility of this phantom was demonstrated by comparing the output of different MRSI sequences with the same nominal resolution. The phantom was scanned with 3 MRSI sequences: 2-D Point Resolved Spectroscopy (PRESS), 2-echo Spin Echo Spectroscopic Imagine (SESI), and 4-echo SESI, all of nominal voxel size $5 \times 5 \times 10 \text{ mm}^3$. A 10 mm thick single-slice T2-weighted image of the phantom was acquired at a position coinciding with the spectroscopic scans (Figure 2). This allowed a proper comparison of the spectroscopic results to the phantom geometry. Cho/Cr ratio maps were calculated for each of the spectroscopic scans.

Comparison of k-space filters

The phantom can also be used to optimize filter parameters. Such use is demonstrated

by comparing the Cho/Cr maps resulting from the same 2-D PRESS sequence using different k-space filters. Since 2-D cosine k-space filters are routinely used on our system to reduce ringing, it was the type of filter chosen for this demonstration. The phantom was scanned with 2-D PRESS of nominal voxel size $5 \times 5 \times 10 \text{ mm}^3$. The data was reconstructed twice; once using no k-space filter and once using a 2-D cosine k-space filter shown in Figure 3. Similar to the previous comparison, a 10 mm thick single-slice T2-weighted image of the phantom was acquired at a position coinciding with the spectroscopic scans to allow for a proper comparison of the spectroscopic results to the phantom geometry.

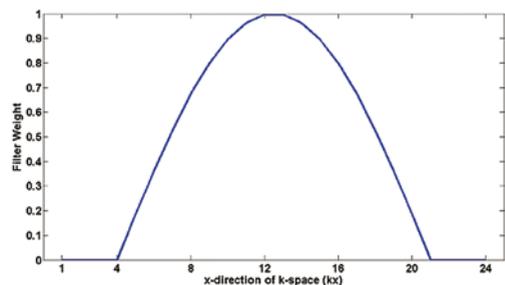

Figure 3. The profile of the 2-D cosine filter in one k-space direction.

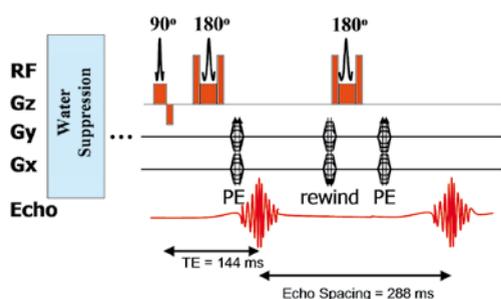

Figure 4. A schematic of a 2-echo SESI MRSI sequence.

Spectroscopic imaging scan parameters

All scans were performed on a Philips Intera 3 T MRI (Philips Medical Systems, Bothell, WA) unit together with a transmit/receive birdcage head coil. In this work two types of sequences were used: 2-D PRESS and SESI. The PRESS sequence is a standard sequence used for many in-vivo MRSI studies, especially those interested in high signal-to-noise.^{10,11}

SESI offers the choice of acquiring more than one echo per repetition, hence decreasing the overall scan time.¹¹ The SESI sequence consists of 2 RF pulses applied on the same plane. The first 90° pulse excites the slice of interest and then a 180° refocusing pulse generates an echo at TE₁. More echoes can be generated by applying subsequent 180° refocusing pulses on the same plane each with a different phase encoding (Figure 4). This is analogous to a fast spin echo sequence in imaging.

In the multi-echo SESI sequences the centre of k-space is filled with the first echoes while the edges are filled with data from the later echoes. This produces a T2 weighting artifact in the form of decreased contrast at high spatial resolution compared to 2-D PRESS or single-echo SESI.

For all sequences the TR was set to 1500 ms, and the TE to 144 ms. The number of phase encodes and FOV was set to 24×24 and 120 mm, respectively, yielding a nominal voxel size of 5×5×10 mm³ for all se-

quences. For the SESI sequences the inter-echo spacing was set to 288 ms.

Prior to running the MRSI scans, second order shimming was established over the volume-of-interest (VOI).¹² Water suppression was achieved by a mix of chemical shift selective (CHESS) suppression and inversion recovery.^{13;14} First, a CHESS excitation pulse for water is applied followed by crusher gradients. This yielded a dephased negative water signal that tends to return to equilibrium through T1 relaxation. The measurement is then acquired at the zero crossing of the water signal in a fashion similar to inversion recovery.

Processing

The raw data acquired from the MRSI scans were processed on the scanner console using MR Systems Intera (release 1.5.4.3) (Philips Medical Systems, Bothell, WA). First, a cosine filter was applied to the raw k-space data to reduce ringing. The data was then reconstructed to xy-space and adoped by a Lorentzian – Gaussian filter to reduce noise. Zero-order phase, inhomogeneities, and eddy currents were corrected using unsuppressed water measurements collected during the scans. Finally, the frequency domain data was exported to Matlab (The MathWorks, Inc., Natick, MA) where it was further analyzed using in-house developed software that calculates the area under different metabolite peaks.

Peak fitting

The in-house developed peak fitting algorithm fitted a sum of Lorentzians to the complex spectra based on seeding values for the chemical shift, estimated peak heights, and full width half maxima (FWHM).¹⁵ A Levenberg-Marquardt algorithm was used to minimize the sum of squares of the difference between the raw spectrum and the

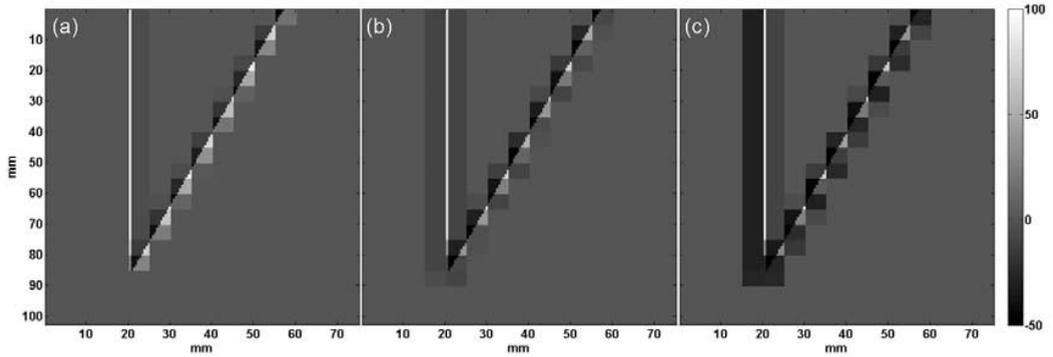

Figure 5. Percentage difference images between simulated $5 \times 5 \text{ mm}^2$ pixel images and the phantom geometry using: (a) no compartment wall, (b) 1 mm wall, (c) 2 mm wall.

Lorentzians to achieve the best fit.¹⁶

The Lorentzian parameters (peak heights, chemical shift, and FWHM) resulting from the peak fitting algorithm were used in the software to analytically calculate the area under the peaks from each spectrum. Since phase was corrected in the processing stage, the real spectrum is assumed to be equal to the absorption spectrum. Hence the area under the peak is calculated as $(\pi/2 \times \text{FWHM} \times \text{peak height})$. Finally, the software produced metabolite area maps, as well as a choline-to-creatine ratio map.

In-plane interpolation of the metabolite maps has been routinely used in the literature to correlate MRSI with CT and MRI images for treatment planning.¹⁷ The interpolation smoothes the appearance of the metabolite maps and allows for better comparison with CT and MRI images. In this work, the metabolite maps were linearly interpolated to 0.5 mm pixels in-plane.

Results and discussion

Effects of the phantom wall material

The rationale behind the choice of the phantom material was to minimize magnetic susceptibility artifacts and partial volume artifacts caused by the presence

of compartment walls of finite thickness. While it has been suggested in the literature that the use of water equivalent glass can solve problems of magnetic susceptibility, the problem of wall-related partial volume artifacts would still persist.⁸

The use of porcine gel as the phantom's building material can remedy both these issues. The magnetic susceptibility of the porcine gel is very close to that of water making susceptibility differences negligible. Furthermore, the lack of a physical compartment wall in this design eliminates the issue of its related partial volume artifacts.

In a simple demonstration conducted in Matlab (The MathWorks, Inc., Natick, MA), the two-dimensional geometry of the phantom was modeled using pixel dimensions of 0.5 mm. Derived from a 2-D PRESS scan of a choline filled phantom, the wedge shaped compartment was assigned arbitrary pixel values of 4000 while the pixels outside the wedge were assigned a value of 1500. A compartment wall was included in the geometric simulation whose thickness was varied between 0 mm and 2 mm and was assigned a pixel value of 0. The pixel values of the 0.5 mm model were then averaged to 5 mm pixels, a resolution achievable by MRSI. Figures 5(a), 5(b), and 5(c) show that with a thickness as small as 1 mm, compartment walls can produce visible artifacts

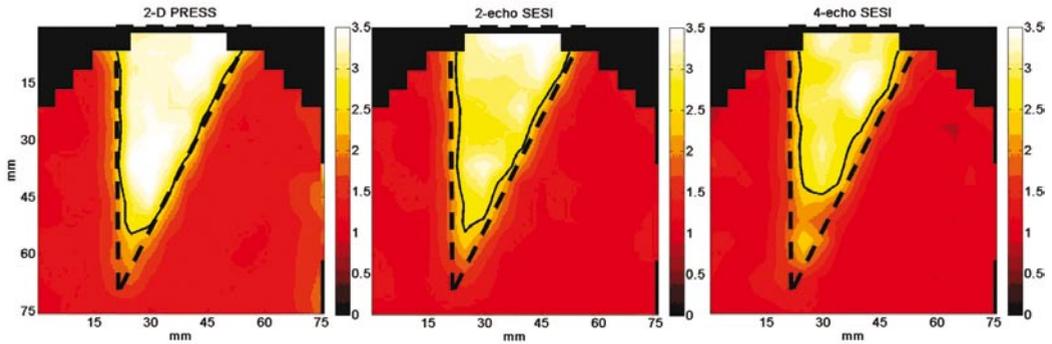

Figure 6. Comparison of the Cho/Cr ratio map and the phantom geometry. The scale represents the Cho/Cr value. The dashed line represents the phantom geometry and the solid line represents the contour at Cho/Cr ≥ 2.5 . The sequences left to right are 2-D PRESS sequence, 2-echo SESI sequence and 4-echo SESI sequence.

that degrade the accuracy and performance of the phantom.

Comparison of MRSI sequences

Three MRSI sequences of the same nominal resolution were used to illustrate the utility of the gel detail phantom. Figure 6 shows the Cho/Cr ratio maps of a 2-D PRESS, a 2-echo SESI, and a 4-echo SESI sequence compared to phantom geometry.

The tip of the wedge forming the high-detail region of the phantom is intended to show differences in high-detail accuracy between the three sequences. From Figure 6, it is apparent that the 2-D PRESS and the 2-echo SESI ratio maps reveal a higher choline-to-creatine ratio extending further into the high detail region of the phantom than in the case of 4-echo SESI. Overall, 2-D PRESS and 2-echo SESI show better conformance to the phantom geometry than 4-echo SESI.

One can quantitatively compare the different sequences by analyzing the deviation between of area of the wedge as shown by the T2 weighted image and the metabolite map. For this purpose the user can choose the suitable tumor contouring criterion for the metabolite maps whether it is a specific metabolite ratio (e.g. Cho/Cr, or Cho/NAA) or z-score (e.g. choline-to-NAA index).^{5;18;19} In this demonstration an arbitrary Cho/Cr

≥ 2.5 was chosen as the tumor contouring criterion. The metabolite maps of the three sequences were automatically contoured at that value and the percentage difference of the areas was found to be 13.7%, 24.4%, and 38.3% for 2-D PRESS, 2-echo SESI, and 4-echo SESI, respectively. Due to the lack of T2 weighting, 2-D PRESS exhibits the smallest deviation from the phantom geometry. The larger deviations shown by multi-echo SESI can be attributed to T2 losses accumulated in acquiring more than one echo per excitation. Such losses are progressively more evident with the increasing number of echoes per excitation.

Comparison of k-space filters

The ability of MRSI to accurately detect tumor boundaries is sensitive to factors such as k-space sampling and filtering. Like the T2 weighting artifacts discussed earlier, the k-space filter parameters can greatly deteriorate tumor boundary accuracy in MRSI. The phantom was used to reveal differences in tumor delineation resulting from changing k-space filtering. Figure 7 shows the Cho/Cr ratio maps of a 2-D PRESS scan of the phantom reconstructed using unfiltered and 2-D cosine filtered k-space respectively. While the filtered dataset produces fewer noise fluctuations in the ratio map, there

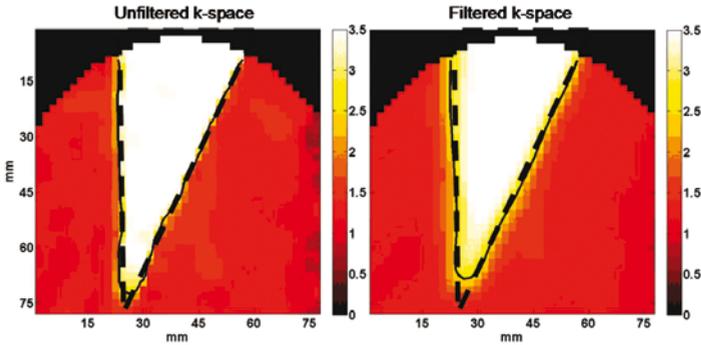

Figure 7. Comparison of the effects of k-space filtering on tumor delineation. The scale represents the Cho/Cr value. The dashed line represents the phantom geometry and the solid line represents the contour at Cho/Cr \geq 2.5.

is a much more prominent transition zone visible along the wedge margin. The difference in tumor delineation between the two reconstructions is clear in the lower high-detail region of the wedge shape.

The phantom can be used to evaluate how the detected tumor volume is influenced by different combinations of k-space sampling and filtering during the development phase of a new MRSI sequence. Furthermore, it is useful as a quality assurance tool to ensure the preservation or improvement of the quality of tumor delineation when developing an MRSI sequence or signal processing methods.

Conclusions

Studies have shown that MRSI has the potential of detecting areas of tumors growth that were otherwise undetectable using conventional imaging. However the ability of MRSI to accurately represent tumor geometry is not always clearly defined by its nominal voxel size, which is influenced by many imaging and processing parameters. It is therefore important to understand and quantify such ability if MRSI is to be used with radiotherapy planning. In this work a detail phantom has been introduced to assist in the process of improving the ability of the spectroscopic imaging sequences to accurately represent the geometry of tumors.

The phantom was developed for assessing the performance of MRSI sequences. Traditionally, MRSI phantoms are susceptible to magnetic susceptibility artifacts and wall-related partial volume artifacts arising from their building material. The use of a porcine gel phantom minimizes the susceptibility artifacts, and the lack of a physical compartmental wall eliminates the associated partial volume artifacts.

The phantom was shown to be successful in demonstrating the differences in tumor boundary definition shown by three MRSI sequences of the same nominal resolution. It was also used to show the differences resulting from applying different k-space filters to the same sequence. There are a number of imaging and filtering parameters that can influence high-resolution contrast of an MRSI sequence. For example, harsh k-space filtering parameters tend to minimize the signal at the edges of k-space. Similarly, increasing the number of echoes acquired per excitation will produce a T2 weighted k-space, resulting in decreased contrast at high spatial-resolution in the metabolite maps. While a sequence may be designed to achieve a desired nominal resolution, the above mentioned factors can influence the spatial accuracy of tumor boundary delineation to an extent which may not be intuitive to the user. The phantom introduced in this work can be used as a development tool to investigate the effects of those im-

aging and filtering parameters on the accuracy of tumor delineation before applying the developed sequences clinically. Finally, the reduced artifacts associated with using porcine gel coupled with its relative ease of construction make this kind of phantom a viable option for evaluating the performance of MRSI sequences in both clinical and scientific settings.

Kakšen je najpogostejši mamografski videz T1a in T1b invazivnih rakov dojk?

Podkrajšek M, Žgajnar J, Hočevar M

Izhodišče. Podatki o mamografskem videzu pod 1 cm velikih invazivnih rakov dojk (RD) so skopi. Avtorji uporabljajo različna merila. Namen naše raziskave je bil ugotoviti najpogostejši mamografski videz majhnih invazivnih RD (T1a in T1b).

Bolniki in metode. V raziskavo je bilo vključenih 100 žensk s 102 invazivnim RD, manjše velikosti (1-10 mm), ki smo jih našli pri mamografiji na Onkološkem inštitutu v 16 mesecih. Mamografski videz smo opisali kot: tumor, tumor s mikrokalcinacijami, samo mikrokalcinacije in drugo (asimetrična zgostitev, arhitekturni nemir).

Rezultati. Najpogosteje smo našli tumor brez kalcinacij (60/102; 59%). Pri 12/102 (11%) je bil viden tumor s kalcinacijami. Samo mikrokalcinacije so bile ugotovljene pri 12/102 (11%) ter asimetrična zgostitev in arhitekturni nemir pri 18 invazivnih RD (18%). Največ invazivnih RD (44/60) je imelo videz zvezdastega tumorja. Odstotek tipa razvejanih mikrokalcinacij je bil višji pri ženskah pod 50. letom starosti.

Zaključek. Najpogostejše mamografski videz majhnih invazivnih RD je ne glede na starost bolnic zvezdast tumor. Kalcinacije z/brez tumorja so pogostejše pri ženskah pod 50. letom starosti.

Obliterativna hepatokavopatija – ultrazvočna in kavografska diagnostika – prikaz primera

Kutlu R

Izhodišča. Obliterativna hepatokavopatija je relativno nov pojem, ki definira primarno trombozo spodnje votle vene in membranozno obstrukcijo spodnje votle vene pri Budd-Chiari sindromu.

Prikaz primera. Prikazan je primer kavografskih in ultrazvočnih sprememb pri popolni zapori spodnje votle vene pri 36 letni bolnici, ki je bila pregledovana zaradi diagnostike posledic B hepatitisa.

Zaključki. Ta bolezen je bila dosedaj prvenstveno zdravljena s kirurškimi posegi, npr. z portalno-mezenteričnim sistemskim odvodom (shuntom) ali s presaditvijo jeter. V zadnjem času pa se v takih primerih enako uspešni tudi interventni radiološki posegi, kot sta transjugularni intrahepatični portosistemski odvod in perkutana angioplastika jetrnih ven s postavitvijo žilnih opornic.

Gastrointestinalni stromalni tumor želodca

Žokalj I, Čulinović-Čaić R, Magaš Z, Pavčec Z, Saghir H, Igrec J, Marotti M

Izhodišča. Gastrointestinalni stromalni tumorji (GIST-i) so najbolj pogosti mezenhimalni tumorji prebavnega trakta. Ne moremo jih preprosto deliti na benigne in maligne, ker je veliko vmesnih oblik. Na potek bolezni znatno vpliva njihova velikost in mitotska aktivnost, prav tako mesto, kjer se pojavijo. Najdemo jih kjerkoli vzdolž prebavnega trakta, v mezenteriju ali omentumu. GIST-i so največkrat benigni tumorji, v 70-80% pa se pojavijo v želodčni steni. V članku predstavljamo primer 70-letne bolnice z želodčno obliko GIST-a.

Prikaz primera. Pri bolnici smo naredili ultrazvočno preiskavo trebuha zaradi tipljive zadržane v epigastriju. Videli smo večinoma hiperehogeno okroglo maso z majhnimi hipoehogenimi areali v centralnem delu. Preiskava z računalniško tomografijo pa je pokazala veliko ekspanzivno maso, heterogene strukture v želodčni steni. Tumor je kazal večji atenuacijski koeficient na periferiji in nižji v centralnem delu. Med operativnim zdravljenjem smo odstranili velik ekzofitičen tumor želodčne stene. Diagnozo GIST želodca smo postavili po patohistološkem in imunohistokemičnem pregledu tumorja.

Zaključki. GIST-i so statistično redki tumorji (0,1%-0,3% vseh gastrointestinalnih tumorjev), a ko najdemo bolnika z okroglo, večinoma ekzofitično tumorsko maso na steni gastrointestinalnega trakta ali peritoneja, moramo pomisliti tudi na GIST. Z ultrazvokom in računalniško tomografijo lahko postavimo klinično predoperativno diagnozo in opredelimo razširjenost bolezni.

**Časovna odvisnost učinkov električnih polj
na celično membrano.
Kritični pregled pomena trajanja električnih pulzov
in njihova terapevtska uporabnost**

Teissié J, Escoffre JM, Rols MP, Golzio M

Izhodišča. Elektroporacija je ena od nevirusnih metod vnosa molekul v celice tkiva in tumorje. Uspešno se uporablja za dostavljanje kemoterapevtikov in tudi genov. Metoda je uporabna pri zdravljenju tumorjev kot tudi pri genski terapiji. Prispevek obravnava časovno komponento elektroporacije pri vnosu malih molekul (< 4 kDa) in procese, ki vplivajo na vnos DNA v celice *in vivo*. Opisani so procesi, ki se dogajajo pred elektroporacijo, med njo (ms) in po njej (ms in h), pri prenosu DNA v celico. Ta proces je sestavljen iz več dogodkov, ki imajo dobro definirano kinetiko. Ne moremo ga opisati kot dogodek, ki tvori luknje v celični membrani, ne kot samo dvostopenjski proces.

Zaključki. Hitri dogodki so v času ns, in so pod vplivom zunanjšega električnega polja, medtem ko so počasnejši dogodki povezani z metabolizmom membrane. Zato je nadaljne raziskovanje dogodkov na membrani pod vplivom električnih polj pomembno za varno uporabo elektroporacije v kliniki.

Prospektivna raziskava kakovosti življenja bolnikov po kombiniranem zdravljenju raka danke

Velenik V, Oblak I, Anderluh F

Izhodišča. Iz poročil v literaturi ni razvidno, da bi trajna stoma poslabšala kakovost življenja bolnikov z lokalno napredovalim rakom danke (T3-4 in/ali N+). Naš namen je bil primerjati kakovost življenja bolnikov z abdominoperinealno amputacijo danke in bolnikov z ohranjeno kontinuiteto črevesa, zdravljenjih s predoperativno radiokemoterapijo v prospektivni raziskavi faze II.

Bolniki in metode. 57 bolnikov je bilo obsevanih 5-krat tedensko in z dnevnim odmerkom 1,8 Gy do skupne doze 45 Gy. Sočasno z obsevanjem so prejeli peroralno kemoterapijo s kapecitabinom v odmerku 825 mg/m²/12 ur. Operacijo smo načrtovali 4-6 tednov po zaključeni predoperativni radiokemoterapiji. Po operaciji so bolniki prejeli 4 kroge kemoterapije. Pri ocenjevanju kakovosti življenja so bolniki, ki so bili po ≥ 2 letih sledenja brez znakov ponovitve bolezni, izpolnili vprašalnika, ki ju je razvila European Organisation for Research and Treatment of Cancer (EORTC): prvi je bil specifičen za bolnike z rakom (EORTC QLQ-C30) in drugi za bolnike z rakom debelega črevesa in danke (EORTC QLQ-C38).

Rezultati. Vprašalnik je izpolnilo 28 od 37 primernih bolnikov (87,5 %). Srednji čas od operacije do izpolnjevanja vprašalnikov je bil 35 mesecev. Pri nobenem vprašanju iz vprašalnikov EORTC QLQ-C30 in EORTC QLQ-C38 med skupinama ni bilo statistično pomembnih razlik v srednjem številu zbranih točk.

Zaključki. Razlike v kakovosti življenja med bolniki s trajno stomo in bolniki z ohranjenim analnim sfinktrom nismo zasledili.

Obvladovanje neželenih učinkov na kožo s kremo z vitaminom K1 pri bolnikih zdravljenih s cetuksimabom

Ocvirk J, Rebersek M

Izhodišča. Cetuksimab je človeško-mišje monoklonalno protitelo proti receptorju za epidermalni rastni dejavnik (EGFR). V kliničnih raziskavah se je izkazal za učinkovitega pri številnih malignih obolenjih. Ob uporabi inhibitorjev EGFR so pogosti neželeni učinki na koži, med katerimi je najpogostejši akniformni izpuščaj. Pri nekaterih bolnikih opazimo tudi kserozo, ekcem, fisure, teleangiektazije, spremembe nohtov in paranihijo, hiperpigmentacija pa je bolj redka. Z dobrim obvladovanjem neželenih učinkov na kožo pomagamo bolnikom in izboljšamo kakovost življenja. V večini primerov je učinkovita standardna uporaba topičnih ali sistemskih antibiotikov ter protivnetnih zdravil. Ključnega pomena pri obvladovanju kožne toksičnosti sta edukacija bolnikov pred pričetkom zdravljenja ter hitro in učinkovito ukrepanje ob prvih znakih neželenih učinkov na kožo.

Namen pričujoče raziskave je bil ocenjevanje neželenih učinkov na kožo med zdravljenjem s cetuksimabom in ugotavljanje učinkovitosti kreme z vitaminom K1.

Metode. Od septembra 2006 do avgusta 2007 smo zdravili 30 bolnikov z razsejanim rakom debelega črevesa in danke s cetuksimabom in kemoterapijo, ki so imeli tudi akniformni izpuščaj zaradi zdravljenja. Sledili smo jih vsaj tri mesece, enkrat tedensko. Za obvladovanje akniformnega izpuščaja smo uporabljali kremo z vitaminom K1 in ureo (Reconval K1[®]). Bolniki so jo pričeli uporabljati neposredno po ugotovljenem pojavu kožne toksičnosti. Kožne neželene učinke smo ocenjevali glede na NCI CTCAE, ver. 3.

Rezultati. Šest od 30 bolnikov je imelo akniformni izpuščaj tretje stopnje, 18 druge in 6 prve stopnje. Reconval K1[®] smo uporabljali dvakrat dnevno. Pri vseh bolnikih smo opazili izboljšanje neželenih učinkov na koži. Srednji čas do izboljšanja je bil 8 dni in 18 dni do znižanja stadija neželenih učinkov vsaj za eno stopnjo.

V nasprotju s podatki o do sedaj zdravljenih bolnikih s cetuksimabom, pri katerih je nastopila 3. stopnja kožne toksičnosti ter je bilo pri vseh priporočeno in tudi nujno znižanje odmerka cetuksimaba, pa pri nekaterih naših bolnikih to ni bilo potrebno. Pri samo 3 od 6 bolnikov s 3. stopnjo kožne toksičnosti smo morali znižati odmerek cetuksimaba.

Pri bolnikih s 1. in 2. stopnjo kožne toksičnosti ni bilo potrebno znižati odmerka ali odložiti zdravljenja. Ob topični uporabi kreme Reconval K1[®] nismo opazili nobenih lokalnih ali sistemskih neželenih učinkov.

Zaključki. Po naših podatkih je to prva objavljena raziskava o učinkovitosti kreme z vitaminom K1 pri zmanjševanju neželenih učinkov na kožo ob zdravljenju s cetuksimabom pri bolnikih z razsejanim rakom debelega črevesa in danke. Reconval K1[®] je učinkovit v obvladovanju kožne toksičnosti pri bolnikih zdravljenih s cetuksimabom. Potrebne bodo nadaljne raziskave za ugotavljanje vpliva na kvaliteto življenja in odgovore na zdravljenje.

Metastaza ledvičnega raka v hipofizi: prikaz primera

Bišof V, Juretić A, Šarić N, Melada A, Perković Z, Radoš M, Padovan Štern R

Izhodišča. Solitarna metastaza ledvičnega raka v hipofizije je zelo redka in le v 7% povzroča simptome bolezni.

Prikaz primera. Opisujemo 52-letnega bolnika, ki je imel motnje vida in glavobole 3 leta po zdravljenju metastatskega ledvičnega raka. Preiskava z magnetno resonanco je pokazala tumor v supraselarnem področju, ki je pritiskal na optično hiasmo. Drugih metastatskih sprememb pa nismo videli. Bolniku smo naredili transsfenoidalno redukcijsko operacijo. Patohistološki pregled, ki je obsegal tudi imunohistološko priskavo, je pokazal, da smo odstranili metastazo svetloceličnega ledvičnega raka.

Zaključki. Naš primer je petindvajseti, ki je opisan v literaturi kot bolnik s simptomatsko metastazo ledvičnega raka v hipofizi.

Fantom za ocenjevanje natančnosti obrisovanja tumorjev z magnetno resonančno spektroskopijo (MRS)

Heikal AA, Wachowicz K, Thomas SD, Fallone BG

Izhodišča. Raziskave so pokazale, da lahko z magnetnoresonančne spektroskopije (MRS) zaznamo področja nenormalne aktivnosti (kot so v tumorju), ki bi jih z običajnimi metodami spregledali. Zaradi vse večjega zanimanja za MRS je pomembno raziskati njeno natančnost pri obrisovanju tumorjev. Kljub temu, da je bilo v izdelavo fantomov za preučevanje učinkovitosti MRS zaporedij vložena že precej truda, so jih večino izdelali iz običajnega ali akrilnega stekla.

Material in metode. V članku predstavljamo fantom iz nehomogene želatine, ki smo ga razvili za ocenjevanje zmogljivosti spektroskopskih slikovnih zaporedij pri določanju geometrijskih oblik tumorjev. Fantom uporabljamo kot alternativo konvencionalnim fantomom iz običajnega in akrilnega stekla namenjenim MRS.

Rezultati. Fantomi iz želatine imajo prednost, ker je njihova magnetna susceptibilnost blizu magnetni susceptibilnosti vode. Poleg tega v članku dokažemo prednosti fantoma brez predelnih sten med deli z različno homogenostjo. Uporabnost fantoma prikažemo s primerjavami med različnimi MRS zaporedji pri isti nazivni ločljivosti ter s primerjavami med različnimi parametri filtriranja.

Zaključki. Zaradi enostavne izdelave in zmanjšanih artefaktov, so fantomi iz želatine zanesljivo orodje za ocenjevanje uspešnosti MRS zaporedij.

March 7-12, 2009

The 34th Annual Meeting of Society of Interventional Radiology will be held in Lake Buena Vista, Florida, USA.

Contact ASTRO, 8280 Willow Oaks Corporate Dr., Suite 500, Fairfax, VA 22031; or call +1 703 502-1550; see <http://www/astro.org>

Cancer therapy

March 11-15, 2009

The NCCN 14th Annual Conference: "Clinical Practice Guidelines & Quality Cancer Care" will be offered in Hollywood, Florida, USA.

Contact National Comprehensive Cancer Network, 275 Commerce Drive, Suite 300, Fort Washington, PA 19034; or phone +1 215 690 0300; or fax +1 215 690 0280; or see <http://www.nccn.org>

Brachytherapy

March 22-26, 2009

The ESTRO teaching course "Modern Brachytherapy Techniques" will take place in Cairo, Egypt.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Radiotherapy

March 23-27, 2009

The ESTRO teaching course "Radiotherapy Treatment Planning, Principles and Practice" will be held in Dublin, Ireland.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Oncology

March 28-31, 2009

The ESTRO teaching course on combined drug-radiation treatment: biological basis, current applications and perspectives will be offered in Berlin, Germany.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Targeted therapies

April 1-5, 2009

The "4th IASLC/ASCO/ESMO International Meeting on Targeted Therapies on Lung Cancer" will be offered in Saint Paul de Vence, France.

E-mail: pia.hirsch@uchsc.edu

Breast cancer

April 2-4, 2009

The ESTRO multidisciplinary teaching course on breast cancer will take place in Lisbon, Portugal.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Molecular oncology

April 26-30, 2009

The ESTRO teaching course "Molecular Oncology for the Radiation Oncologist" will take place in Santorini, Greece.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Radiation oncology

April 27-29, 2009

The international IAEA's conference "Advances in Radiation Oncology (ICARO)" will be held in Vienna, Austria.

Contact ASTRO, 8280 Willow Oaks Corporate Dr., Suite 500, Fairfax, VA 22031; or call +1 703 502-1550; see <http://www/astro.org>

Thoracic oncology

May 1-3, 2009

The European Multidisciplinary Conference in Thoracic Oncology (EMCTO) will take place in Lugano, Switzerland.

Contact EMCTO Conference Secretariat, c/o ESMO Congress Department, Via Luigi Taddei 4, CH-6962 Viganello-Lugano, Switzerland; or fax +41 (0)91 973 19 18, or see www.emcto.org

Rectal cancer

May 10-12, 2009

The ESTRO multidisciplinary teaching course on evidence and research in rectal cancer will take place in Rome, Italy.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Radiotherapy

May 10-14, 2009

The ESTRO teaching course on radiotherapy with protons and ions will be offered in Villingen, Switzerland.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Radiotherapy

May 17-21, 2009

The ESTRO teaching course on IMRT and other conformal techniques in practice will be held in Milan, Italy.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Thyroid cancer

May 27-31, 2009

The "World Congress on Thyroid Cancer" will be held in Toronto, Canada.

Contact ASTRO, 8280 Willow Oaks Corporate Dr., Suite 500, Fairfax, VA 22031; or call +1 703 502-1550; see <http://www/astro.org>

Clinical oncology

May 29 – June 2, 2009

The American Society of Clinical Oncology Conference (ASCO 2009) will be offered in Orlando, USA.

E mail enews@asco.org; or see <http://www/asco.org>

Clinical trial statistics

June 9-12, 2009

The EORTC course "Clinical Trial Statistics for Non Statisticians" will be held in Brussels, Belgium.

See <http://www.eortc.be/Seminar/Educationpgm/Stats2009/Default.htm>

Oncology

June 20-26, 2009

The ECCO-AACR-ASCO workshop "Methods in Clinical Cancer Research" will be offered in Flims, Switzerland.

Contact the Workshop Coordinator Mrs. Kaat Cumps at kaat.cumps@ecco-org.eu; or see <http://www.ecco-org.eu> (go to the section Education/Flims/Flims11)

Radiotherapy

June 21-25, 2009

The ESTRO teaching course "Imaging for Target Volume Determination in Radiotherapy" will be held in Tours, France.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Radiation oncology

June 25-27, 2009

The "MASCC/ISOO 2009 International Symposium of Supportive Care in Cancer: Multinational Association of Supportive Care of Cancer/International Society of Oral Oncology" will be held in Rome, Italy.

Contact ASTRO, 8280 Willow Oaks Corporate Dr., Suite 500, Fairfax, VA 22031; or call +1 703 502-1550; see <http://www/astro.org>

Paediatric oncology

June 28-30, 2009

The ESTRO teaching course on paediatric oncology will be offered in Brussels, Belgium.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Prostate cancer

June 28-30, 2009

The ESTRO teaching course on brachytherapy for prostate cancer will take place in Istanbul, Turkey.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Radiotherapy

June 28 – July 2, 2009

The ESTRO teaching course on 2D-3D planning and imaging will be offered in St Petersburg, Russia.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estros-events.org>

Oncology

July 2-5, 2009

The Educational Cancer Convention (ECCLU) will be held in collaboration with European Society for Medical Oncology in Lugano, Switzerland.

E-mail www.cmelcher@eso.net; or see www.eso.net

Lung cancer

July 31 - August 4, 2009

The "13th World Conference on Lung Cancer" will be offered in San Francisco, USA.

Contact Conference Secretariat International Conference Services Ltd., Suite 2101 - 1177 West Hastings Street, Vancouver, BC Canada V6E 2K3; or call +1 604 681 2153; or e-mail wclc2009@meet-ics.com; or see <http://www.2009worldlungcancer.org/>

Radiotherapy

August 30 – September 3, 2009

The 19th Biennial ESTRO Conference" will be held in Maastricht, the Netherlands.

Phone +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estros-events.org>

Oncology

September 4-8, 2009

The "34th ESMO Congress" will take place in Vienna, Austria.

Contact ESMO Head Office, Congress Department, Via La Santa 7, CH-6962 Viganello-Lugano, Switzerland; or +41 (0)91 973 19 19; or fax +41 (0)91 973 19 18; or e-mail congress@esmo.org; or see <http://www.esmo.org>

Medical physics

September 7-12, 2009

The "World Congress 2009 – Medical Physics and Biomedical Engineering" will take place in Munich, Germany.

See <http://www.wc2009.org/world-congress-2009>

Brachytherapy

September 10-12, 2009

The ESTRO teaching course "3D Image-Based Brachytherapy for Gynaecological Malignancies" will be offered in Amsterdam, The Netherlands.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estros-events.org>

Radiation oncology

September 13-16, 2009

The "8th International Conference on Dose, Time and Fractionation in Radiation Oncology" will be held in Madison, Wisconsin, USA.

Contact ASTRO, 8280 Willow Oaks Corporate Dr., Suite 500, Fairfax, VA 22031; or call +1 703 502-1550; see <http://www/astro.org>

Oncology

September 20-24, 2009

The "15th ECCO and 34th ESMO Multidisciplinary Congress" will be offered in Berlin, Germany.

See <http://www.ecco.org.eu>

Nuclear medicine

October 10-14, 2009

The "EANM'09 Annual Congress of the European Association of Nuclear Medicine" will take place in Barcelona, Spain.

Contact EANM Executive Secretariat and call +43 1 212 80 30; or fax +43 1 212 80 309; or e-mail office@eanm.org; or see <http://www.eanm.org>

Radiation oncology

October 11-16, 2009

The ESTRO teaching course Evidence Based Radiation Oncology: Methodological Basis and Clinical Application " will be offered in Vienna, Austria.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Lung Cancer

October 15-17, 2009

The ESTRO multidisciplinary teaching course on lung cancer will be held in Prague, Czech Republic.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Radiobiology

October 18-23, 2009

The ESTRO teaching course on basic clinical radiobiology will be offered in Toledo, Spain.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Therapeutic radiology and oncology

November 1-5, 2009

The "American Society for Therapeutic Radiology and Oncology Annual Meeting ASTRO" will take place in Chicago, USA.

Contact ASTRO, 8280 Willow Oaks Corporate Dr., Suite 500, Fairfax, VA 22031; or call +1 703 502-1550; or see <http://www.astro.org>

Radiotherapy

November 15-19, 2009

The ESTRO teaching course on IMRT and other conformal techniques in practice will take place in Gliwice, Poland.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

PET in radiation oncology

November 21-22, 2009

The ESTRO / EANM educational seminar on PET in radiation oncology will take place in Vienna, Austria.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

PET in radiation oncology

December 13-17, 2009

The ESTRO teaching course on image-guided radiotherapy in clinical practice will take place in Brussels, Belgium.

Contact ESTRO office, Avenue E. Mounierlaan, 83/12, B-1200 Brussels, Belgium; or call +32 2775 93 40; or fax 32 2779 5494; or e-mail events@estro.org; or see <http://www/estro-events.org>

Head and neck cancer

February 25-27, 2010

The multidisciplinary symposium on head and neck cancer will be offered in Chandler, Arizona, USA.

Contact ASTRO, 8280 Willow Oaks Corporate Dr., Suite 500, Fairfax, VA 22031; or call +1 703 502-1550; see <http://www/astro.org>

Clinical oncology

June 4-8, 2010

The American Society of Clinical Oncology Conference (ASCO 2010) will be offered in Chicago, USA.

E mail enews@asco.org; or see <http://www/asco.org>

Oncology

October 8-12, 2010

The "35th ESMO Congress" will take place in Milan, Italy.

Contact ESMO Head Office, Congress Department, Via La Santa 7, CH-6962 Viganello-Lugano, Switzerland; or call +41 (0)91 973 19 19; or fax +41 (0)91 973 19 18; or e-mail congress@esmo.org; or see <http://www.esmo.org>

Nuclear medicine

October 9-13, 2010

The "EANM'10 Annual Congress of the European Association of Nuclear Medicine" will take place in Vienna, Austria.

Contact EANM Executive Secretariat and call +43 1 212 80 30; or fax +43 1 212 80 309; or e-mail office@eanm.org; or see <http://www.eanm.org>

Therapeutic radiology and oncology

October 31 – November 4, 2010

The "American Society for Therapeutic Radiology and Oncology Annual Meeting ASTRO" will take place in San Diego, California, USA.

Contact ASTRO, 8280 Willow Oaks Corporate Dr., Suite 500, Fairfax, VA 22031; or call +1 703 502-1550; or see <http://www.astro.org>

Clinical oncology

June 3-7, 2011

The American Society of Clinical Oncology Conference (ASCO 2010) will be offered in Chicago, USA.

E mail enews@asco.org; or see <http://www.asco.org>

Lung cancer

July 3-7, 2011

The "14th World Conference on Lung Cancer" will be offered in Amsterdam, The Netherlands.

See <http://www.iaslc.org>

Oncology

September 23-27, 2011

The "16th ECCO and 36th ESMO Multidisciplinary Congress" will be offered in Stockholm, Sweden.

See <http://www.ecco-org.eu>

Nuclear medicine

October 15-19, 2011

The "EANM'11 Annual Congress of the European Association of Nuclear Medicine" will take place in Birmingham, United Kingdom.

Contact EANM Executive Secretariat and call +43 1 212 80 30; or fax +43 1 212 80 309; or e-mail office@eanm.org; or see <http://www.eanm.org>

Oncology

September 27 – October 1, 2013

The "17th ECCO and 38th ESMO Multidisciplinary Congress" will be offered in Amsterdam, The Netherlands.

See <http://www.ecco-org.eu>

Lung cancer

2013

The "15th World Conference on Lung Cancer" will be offered in Sydney, Australia.

See <http://www.iaslc.org>

As a service to our readers, notices of meetings or courses will be inserted free of charge.

Please send information to the Editorial office, Radiology and Oncology, Zaloška 2, SI-1000 Ljubljana, Slovenia.

Activity of "Dr. J. Cholewa" Foundation for Cancer Research and Education – a report for the final quarter of 2008

Docent Dr. J. Cholewa Foundation for Cancer Research and Education continues to support the activities and advancement of oncology related sciences and is of opinion that excellent and unorthodox ideas must not be prevented to succeed for the simple lack of funding. It primarily supports cancer research and education activities in Slovenia, it continues to assess carefully the requests for research grants and scholarships submitted by Slovenian experts in oncology and other associated scientific activities, and helps putting resulting advances in cancer therapy in practice.

The "Docent Dr. L. Cholewa Foundation for Cancer Research and Education« continues to support the regular publication of "Radiology and Oncology" international medical scientific journal, that is edited, published and printed in Ljubljana, Slovenia. This support emphasizes the need for the spread of information advances in experimental and clinical cancer research to professionals and interested individuals in public in Slovenia and elsewhere. "Radiology and Oncology" is an open access journal, available free of charge on its own website, thus allowing its users and readers to access without hindrance.

The Foundation considers the support of the publication of the results from cancer research in Slovenia and from Slovenian authors in international scientific journals and other means of communication worldwide as one of its main activities. Its careful assessment of requests and proposals for research grants and scholarships submitted by experts in oncology and other associated scientific activities serves this goal in accordance with the spread of advanced knowledge of therapy and education in cancer.

LABORMED

ZASTOPA PODJETJA:

MENTOR

Prsni vsadki napolnjeni s silikonskim gelom, ekspanderji in drugi pripomočki pri rekonstrukciji dojke

Köttermann (Nemčija):

laboratorijsko pohištvo, varnostne omare za kisline, luge, topila, pline in strupe, ventilacijska tehnika in digestorji

Angelantoni scientifica (Italija):

hladna tehnika in aparati za laboratorije, transfuzije, patologijo in sodno medicino

CORNING

Corning (Amerika):

specialna laboratorijska plastika za aplikacijo v imunologiji, mikrobiologiji, virologiji, ipd., mehanske eno- in večkanalne pipete in nastavki

MICRONIC

Micronic (Nizozemska):

sistemi za shranjevanje vzorcev, pipete, nastavki za pipete

Implantech

There's No Reason to Operate with Anyone Else

Implantech (Amerika):

obrazni in glutealni vsadki

BIOMERICA

Biomerica (Amerika):

hitri testi za diagnostiko, EIA /RIA testi

EHRET

Ehret (Nemčija):

Laminar flow tehnika, inkubatorji, sušilniki, suhi sterilizatorji in oprema za laboratorijsko vzrejo živali - kletke

Dako (Danska):

testi za aplikacijo v imunohistokemiji, patologiji, mikrobiologiji, virologiji, mono- in poliklonalna protitelesa

Sakura finetek (Evropa):

aparati za pripravo histoloških preparatov: mikrotinkotomi, zalivalci, tkivni procesorji, barvalci, pokrivala

IBS INTEGRA

Integra Biosciences (Čvica):

laboratorijska oprema za mikrobiologijo, biologijo celic, molekularno biologijo in biotehnologijo

SpectrumDesigns MEDICAL (Amerika):

moški pektoralni vsadki

byron

Byron (Amerika):

liposuktorji in kanile za liposukcijo

ERBITUX – izbira za izboljšano učinkovitost

- Za zdravljenje metastatskega raka debelega črevesa in danke
- Za zdravljenje napredovalega raka glave in vrata v kombinaciji z radioterapijo

Merck Serono Onkologija / biološko zdravljenje za boljšo kakovost življenja

Erbitux 5 mg/ml raztopina za infundiranje (skrajšana navodila za uporabo)

Cetuksimab je rekombinantno IgG protiteleso, usmerjeno proti receptorju za epidermalni rastni faktor (EGFR). **Terapevtske indikacije:** Zdravilo Erbitux je indicirano za zdravljenje bolnikov z metastatskim kolorektalnim rakom in rektalnim tipom KRAS v kombinaciji s kemoterapijo in kot sorodno zdravilo pri bolnikih, pri katerih zdravljenje z oksaliplatinom in irinotekanom ni bilo uspešno. Zdravilo Erbitux je v kombinaciji z radioterapijo indicirano za zdravljenje bolnikov z lokalno napredovalim rakom skvamoznih celic glave in vrata.

Odmerek in način uporabe: Zdravilo Erbitux pri vseh indikacijah infundirajte enkrat na teden. Začetni odmerek je 400 mg cetuksimaba na m² telesne površine. V naslednjih tedenskih odmerkih so vsaki po 250 mg/m².

Kontraindikacije: Zdravilo Erbitux je kontraindicirano pri bolnikih z znano hudo preobčutljivo reakcijo (3. ali 4. stopnje) na cetuksimab. **Posebna opozorila in previdnostni ukrepi:** Če pri bolniku nastopi blaga ali zmerna reakcija, povezana z infundiranjem, lahko zmanjšate hitrost infundiranja. Priporočljivo je, da ostane hitrost infundiranja na nižji vrednosti tudi po vseh naslednjih infuzijah. Če se pri bolniku pojavi huda kožna reakcija (3. stopnje po kritérijih US National Cancer Institute, Common Toxicity Criteria) NCI-CTC), razen prekinite terapijo s cetuksimabom. Z zdravljenjem smete nadaljevati le, če se je reakcija povrnila do 2. stopnje. Priporočila se dobilance koncentracije elektrolitov v serumu pred zdravljenjem in periodično med zdravljenjem s cetuksimabom. Po potrebi se priporoča nadomeščanje elektrolitov. Posebna previdnost je potrebna pri oslajenih bolnikih in pri bolih z obstoječo určno-pljučno boleznijo. Neželeni učinki: Zelo pogosti (≥ 1/10): driska, blaga do zmerne povečanje jetrnih encimov, kožne reakcije, blage ali zmerne reakcije, povezane z infundiranjem, blaga do zmerne mukozitis. Pogosti (≥ 1/100, < 1/10): konjunktivitis, hude reakcije, povezane z infundiranjem. Pogostost ni znana: Opazilo se je progresivno zniževanje nivoja magnezija v serumu, ki pri nekaterih bolnikih povzroča hudo hipomagnezijo. Glede na resnost so opazili tudi druge elektrolitske motnje, večinska hipokalciemija ali hipokalcemija. **Posebna navodila za shranjevanje:** Shranjujte v hladilniku (2 °C – 8 °C). Ne zamrzujte. **Vrsta ovojnine in vsebina:** 1 viala po 20 ml ali 100 ml. Inveznik dovoljenje za promet: Merck KGaA, 64271 Darmstadt, Nemčija. Podrobne informacije o zdravilu so objavljene na spletni strani Evropske agencije za zdravila (EMA) <http://www.ema.europa.eu>.

Dodatne informacije so vam na voljo pri Merck & Co., Dunajska cesta 119, 1000 Ljubljana. Tel: 01 580 3810, faks: 01 506 3831, e. pošta: info@merck.si

Temodal 20 mg, 100 mg, 140mg, 180 mg, 250 mg.

Sestava zdravila: Vsaka kapsula zdravila Temodal vsebuje 20 mg, 100 mg, 140 mg, 180 mg ali 250 mg temozolomida.

Terapevtske indikacije Temodal kapsule so indikacije za zdravljenje bolnikov z:

- za zdravljenje novo diagnosticiranega glioblastoma multiforme, sočasno z radioterapijo in kasneje kot monoterapija

- malignim gliomom, na primer multiformnim glioblastomom ali anaplastičnim astrocitomom, ki se po standardnem zdravljenju ponovi ali napreduje.

Odmerjanje in način uporabe Temodal smejo predpisati le zdravniki, ki imajo izkušnje z zdravljenjem možganskih tumorjev. **Odrasli bolniki z novo diagnosticiranim glioblastomom multiforme** Temodal se uporablja v kombinaciji z žarično radioterapijo (tj. začasno terapijo), temu pa sledi do 6 ciklov monoterapije z temozolomidom. **Faza sočasne terapije** Zdravilo Temodal naj bolnik jemlje peroralno v odmerku 75 mg/m² na dan 42 dni, sočasno z žarično radioterapijo (60 Gy, danih v 30 dnevih odmerkih). Odmerka ne boste zmanjševali, vendar se boste vsak teden odločili o morebitni odločitvi jemanja temozolomida ali njegovi skrajni na podlagi izterjani hematološke in nehematološke toksičnosti. Zdravilo Temodal lahko bolnik jemlje ves čas 42-dnevne obdobja sočasne terapije do 49 dni, če so izpolnjeni vsi od naslednjih pogojev: absolutno število nevtrilicov $\geq 1,5 \times 10^9/l$, število trombocitov $\geq 100 \times 10^9/l$, skupni kriteriji toksičnosti (SKT) za nehematološko toksičnost ≤ 1 , stopnje (z izjemo alopecije, slabosti in bruhanja). Med zdravljenjem morate pri bolniku enkrat na teden pregledati celotno krvno sliko. **Faza monoterapije** Štiri tedne po zaključku faze sočasne zdravljenja z zdravilom Temodal in radioterapijo naj bolnik jemlje zdravilo Temodal do 6 ciklov monoterapije. V 1. ciklu (monoterapija) je odmerek zdravila 150 mg/m² enkrat na dan 5 dni, temu pa naj sledi 23 dni brez terapije. Na začetku 2. cikla odmerek povečate na 200 mg/m², če je SKT za nehematološko toksičnost za 1. cikel stopnje ≤ 2 (z izjemo alopecije, slabosti in bruhanja), absolutno število nevtrilicov (AN) $\geq 1,5 \times 10^9/l$ in število trombocitov $\geq 100 \times 10^9/l$. Če odmerka niste povežali v 2. ciklu, ga v naslednjih ciklih ne smete povečavati. Ko pa odmerek enkrat povečate, naj ostane na ravni 200 mg/m² na dan v prvih 5 dneh vsakega naslednjega ciklusa, razen če nastopi toksičnost. Med zdravljenjem morate pregledati celotno krvno sliko na 22. dan (21 dni po prvem odmerku zdravila Temodal).

Ponavljajoči se ali napredujoči maligni gliom Odrasli bolniki Posamezen cikel zdravljenja traja 28 dni. Bolniki, ki še niso bili zdravljeni s kemoterapijo, naj jemljejo Temodal peroralno v odmerku 200 mg/m² enkrat na dan prvih 5 dni, temu pa naj sledi 23-dnevni premer (skupaj 28 dni). Pri bolnikih, ki so že bili zdravljeni s kemoterapijo, je začetni odmerek 150 mg/m² enkrat na dan, v drugem ciklu pa se poveča na 200 mg/m² enkrat na dan 5 dni, če ni bilo hematoloških toksičnih učinkov (glejte poglavje 4.4). **Pediatrični bolniki** Pri bolnikih starih 3 leta ali starejših, posamezen cikel zdravljenja traja 28 dni. Temodal naj jemljejo peroralno v odmerku 200 mg/m² enkrat na dan prvih 5 dni, potem pa naj sledi 23-dnevni premer (skupaj 28 dni). Otroci, ki so že bili zdravljeni s kemoterapijo, naj prejmejo začetni odmerek 150 mg/m² enkrat na dan 5 dni z povečanjem na 200 mg/m² enkrat na dan 5 dni v naslednjem ciklusu, če ni bilo hematoloških toksičnih učinkov (glejte poglavje 4.4). **Bolniki z metastazami v delovanju jeter ali ledvic** Pri bolnikih z blagimi ali zmernimi motnjami v delovanju jeter je farmakokinetika temozolomida podobna kot pri tistih z normalnim delovanjem jeter. Podatki o uporabi zdravila Temodal pri bolnikih z hudimi motnjami v delovanju jeter (razred III po Child-u) ali motnjami v delovanju ledvic niso na voljo. Na podlagi farmakokinetičnih lastnosti temozolomida obstaja majhna verjetnost, da bo pri bolnikih z hudimi motnjami v delovanju jeter ali ledvic potrebno zmanjšanje odmerka zdravila. Kljub temu je potrebna previdnost pri uporabi zdravila Temodal pri teh bolnikih. **Starejši bolniki:** Analiza farmakokinetike je pokazala, da starost ne vpliva na odstek temozolomida. Kljub temu je potrebna posebna previdnost pri uporabi zdravila Temodal pri starejših bolnikih. **Način uporabe** Temodal mora bolnik jemati na tečje. Temodal kapsule mora bolnik pogoltniti cele s kozarcem vode in jih ne sme odpirati ali žvečiti. Predpisani odmerek mora vzeti v obliki najmanjšega možnega števila kapsul. Pred jemanjem zdravila Temodal ali po njem lahko bolnik vzame antiepileptik. Če po zaužitju odmerka bruha, ne sme še isti dan vzeti drugega odmerka. **Kontraindikacije** Temodal je kontraindiciran pri bolnikih, ki imajo v anamnezi preobčutljivostne reakcije na sestavine zdravila ali na dikarbazon (DTC). Temodal je kontraindiciran tudi pri bolnikih s hudo mielosupresijo. Temodal je kontraindiciran pri ženskah, ki so noseče ali dojijo.

Posebna opozorila in previdnostni ukrepi Plazno preiskujanje podaljšanih 42-dnevne obdobja zdravljenja je pokazalo, da imajo bolniki, ki so sočasno prejeli zdravilo Temodal in radioterapijo, še posebej veliko tveganje za nastanek pljučnice zaradi okužbe s *Pneumocystis carinii* (PCP). Profilaksa proti tvorbi pljučnice je bolj potrebna pri vseh bolnikih, ki sočasno prejema zdravilo Temodal in radioterapijo v okviru 42-dnevne obdobja zdravljenja (do največ 49 dni, ne glede na število limfocitov). Če nastopi limfopenija, mora bolnik nadzorovati s profilakso, dokler se limfopenija ne poravná na stopnjo ≤ 1 . **Antiepileptična terapija:** Z jemanjem zdravila Temodal sta zelo pogosto povezana slabost in bruhanje. **Laboratorijske vrednosti:** Pred jemanjem zdravila morata biti izpolnjena naslednja pogoja za laboratorijske izvide: ANC mora biti $\geq 1,5 \times 10^9/l$ in število trombocitov $\geq 100 \times 10^9/l$. Na 22. dan (21 dni po prvem odmerku) ali v roku 48 ur od navedenega dne, morate pregledati celotno krvno sliko in jo nato spremljati vsak teden, dokler ni ANC nad $1,5 \times 10^9/l$ in število trombocitov nad $100 \times 10^9/l$. Če med katerikoli ciklusu ANC pade na $< 1,0 \times 10^9/l$ ali število trombocitov na $< 50 \times 10^9/l$, morate odmerek zdravila v naslednjem ciklusu zmanjšati za eno odmerko stopnjo. Odmerne stopnje so 100 mg/m², 150 mg/m² in 200 mg/m². Najmanjši priporočeni odmerek je 100 mg/m². **Moški bolniki** Temozolomid lahko deluje genotoksično, zato morate moškim, ki se zdravijo z temozolomidom svetovati, da naj ne zaplodijo otroka še šest mesecev po zdravljenju. **Interakcije** Sočasna uporaba zdravila Temodal in ranitidina ni povzročila spremembe obsega absorpcije temozolomida ali monometilhidrazinimidazol karboksamida (MTHC). Jemanje zdravila Temodal s hrano je povečalo 33 % zmanjšanje C_{max} in 9 % zmanjšanja površine pod krivuljo (AUC). Kar ne moremo izključiti možnost, da bi bila sprememba C_{max} lahko klinično pomembna, naj bolniki jemljejo zdravilo Temodal brez hrane. Analiza populacijske farmakokinetike v preskušanih druge faze je pokazala, da sočasna uporaba deksametazona, prokloperazona, lomitina, karbamazepina, ondansetrona, antagonistov receptorjev H₂ ali fenobarbitala ne spremeni očistka temozolomida. Sočasno jemanje z valprojevo kislino je bilo povezano z majhnim, a statistično značilnim zmanjšanjem očistka temozolomida. Uporaba zdravila Temodal v kombinaciji z drugimi mielosupresivnimi učinkovinami lahko povzroči večjo mielosupresijo. **Nosečnost** Študij na nosečih ženskah ni bilo. Predklinične študije na podganah in kunčih z odmerkom 150 mg/m² so pokazale teratogenost in/ali toksičnost za plod. Zato naj noseče ženske računata na bi jemale zdravila Temodal. Če pa je uporaba v času nosečnosti najna, morate bolnico opozoriti na možno nevarnost zdravila za plod. Zorokam v rudi dobi svežilo, naj med zdravljenjem z zdravilom Temodal preprosto zanese. **Dojenje** Ni znano, ali se temozolomid izloča v materino mleko, zato ženske, ki dojijo, ne smejo jemati zdravila Temodal. **Neželene učinki** V kliničnih preskušanjih so bili najpogostejši neželene učinki, povezani z zdravljenjem, prebavne motnje, natančneje slabost (43 %) in bruhanje (36 %). Oba učinka sta bila ponavadi 1. ali 2. stopnje (od 0 do 5) po bruhanju v 24 urah in sta prenehala sama, ali pa ju je bilo mogoče hitro odpraviti s standardnim antiepileptičnim zdravljenjem. Incidenca hude slabosti in bruhanja je bila 4 %. Laboratorijski izvidi: trombocitopenija in: nestropenija 3. in 4. stopnje sta se pojavili pri 19 % in 17 % bolnikov, zdravljenih zaradi malignega glioma. Zaradi nju je bila potrebna hospitalizacija in/ali prekinitve zdravljenja z zdravilom Temodal pri 8 % in 4 % bolnikov. Mielosupresija je bila predeljavna (poravnala se je pojavila v prvih nekaj ciklih in je bila najrazlediteja med 21. in 28. dnevni okrevanje pa je bilo hitro, ponavadi v 1 do 2 tednih). Opazili niso nobenih dokazov kumulativne mielosupresije. Trombocitopenija lahko poveča tveganje za pojav krvavitev, nestropenija ali levkopenija pa tveganje za okužbo. **Imetnik dovoljenja za promet** SP Evrope 73, rue de Stalle 8-1150 Bruzelsko Belgija. **Način in režim izdaje** Zdravilo se izdaja samo na recept, uporablja pa se pod posebnim nadzorom zdravnika specialista ali od njega pooblaščenega zdravnika. **Datum priprave informacije** oktober 2007.

 Schering-Plough

Temodal®
temozolomid

Resnični napredek

Pri na novo odkritem glioblastomu multiforme in malignih gliomih, ki se ponovijo ali napredujejo.

Poenostavljeno zdravljenje

Z dvema novima jakostima

140 mg in 180 mg Temodal

- Možnost prejemanja manjšega števila kapsul
- Boljša sprejemljivost in sodelovanje bolnika
- Natančno odmerjanje
- Barvne kapsule za enostavnejšo dnevno uporabo

SKRAJŠAN POVZETEK GLAVNIH ZNAČILNOSTI ZDRAVILA

Ime zdravila: Tarceva 25 mg/100 mg/150 mg filmsko obložene tablete

Kakovostna in količinska sestava: Ena filmsko obložena tableta vsebuje 25 mg, 100 mg ali 150 mg erlotiniba (v obliki erlotinibijevega klorida).

Terapevtske indikacije: **Neobnovnelčni rak pljuč.** Zdravilo Tarceva je indicirano za zdravljenje bolnikov z lokalno napredovalim ali metastatskim neobnovnelčnim rakom pljuč po neuspehu vsaj ene predhodne kemoterapije. Pri predpisovanju zdravila Tarceva je treba upoštevati dejavnike, povezane s podaljšanim preživetjem. Konstnega vpliva na podaljšanje smrtelnosti ali drugih klinično pomembnih učinkov zdravljenja niso dokazali pri bolnikih z EGFR-negativnimi tumorji. **Rak trebušne slinavke.** Zdravilo Tarceva je v kombinaciji z gemcitabinom indicirano za zdravljenje bolnikov z metastatskim rakom trebušne slinavke. Pri predpisovanju zdravila Tarceva je treba upoštevati dejavnike, povezane s podaljšanim preživetjem. Konstnega vpliva na podaljšanje preživetja niso dokazali za bolnike z lokalno napredovalno boleznijo.

Odmerjanje in način uporabe: Zdravljenje z zdravilom Tarceva mora nadzorovati zdravnik z izkušnjami pri zdravljenju raka. Zdravilo Tarceva vzamemo najmanj eno uro pred zaužitjem hrane oziroma dve uri po tem. Kadarkoli je potrebno odmerek prilagoditi, ga zmanjšujemo v korakih po 50 mg. Pri sočasnem jemanju substratov in modulatorjev CYP3A4 bo morda potrebna prilagoditev odmerka. Pri dajanju zdravila Tarceva bolnikom z jetrno okvaro je potrebna previdnost, če se pojavijo bodi neželeni učinki ali pride v poštev zmanjšanje odmerka ali prekinitev zdravljenja z zdravilom Tarceva. Uporaba zdravila Tarceva pri bolnikih s hudo jetrno ali ledvično okvaro ter pri otrocih ni priporočljiva. **Neobnovnelčni rak pljuč.** Priporočeni dnevni odmerek zdravila Tarceva je 150 mg. **Rak trebušne slinavke.** Priporočeni dnevni odmerek zdravila Tarceva je 100 mg, v kombinaciji z gemcitabinom. Pri bolnikih, pri katerih se kožni izpuščaj v prvih 4 do 8 tednih zdravljenja ne pojavi, je treba ponovno pretehtati nadaljnje zdravljenje z zdravilom Tarceva.

Kontraindikacije: Huda preobčutljivost za erlotinib ali katero koli pomožno snov.

Posebna opozorila in previdnostni ukrepi: Močni induktorji CYP3A4 lahko zmanjšajo učinkovitost erlotiniba, močni zaviralci CYP3A4 pa lahko povečajo toksičnost. Sočasemu zdravljenju s temi zdravili se je treba izogibati. Bolnikom, ki kadijo, je treba svetovati, naj prenehajo kaditi, saj so plazemske koncentracije erlotiniba pri kadilcih zmanjšane v primerjavi s plazemskimi koncentracijami pri nekadilcih. Verjetno je, da je velikost zmanjšanja klinično pomembna. Pri bolnikih, pri katerih se akutne pojave novo in/ali poslabšajo neposredni pljučni simptomi, kot so dispneja, kašelj in vročina, je zdravljenje z zdravilom Tarceva treba prekiniti, dokler ni znana diagnoza. Bolnike, ki se sočasno zdravijo z erlotinibom in gemcitabinom, je treba skrbno spremljati zaradi možnosti pojavnosti toksičnosti, podobni intersticijski pljučni bolezni. Če je ugotovljena intersticijska pljučna bolezen, zdravilo Tarceva ukineмо in uvedemo ustrezno zdravljenje. Pri približno polovici bolnikov, ki so se zdravili z zdravilom Tarceva, se je pojavila driska. Zmerno do hudo drisko zdravimo z loperamidom. V nekaterih primerih bo morda potrebno zmanjšanje odmerka. V primeru hude ali dolgotrajne driske, navzee, anoreksije ali bruhanja, povezanih z dehidracijo, je zdravljenje z zdravilom Tarceva treba prekiniti in dehidracijo ustrezno zdraviti. O hipokalciemiji in ledvični odpovedi so poročali redko. Posebno pri bolnikih z dejavniki tveganja (sočasno jemanje drugih zdravil, simptomi, bolezen ali drugi dejavniki, vključno z visoko starostjo) moramo, če je driska huda ali dolgotrajna oziroma vodi v dehidracijo, zdravljenje z zdravilom Tarceva prekiniti in bolnikom zagotoviti intenzivno intravensko rehidracijo. Dodatno je treba pri bolnikih s prisotnim tveganjem za razvoj dehidracije spremljati ledvično delovanje in serumske elektroлите, vključno s kalijem. Pri uporabi zdravila Tarceva so poročali o redkih primerih jetrne odpovedi. K njenemu nastanku je lahko pripomogla predhodno obstoječa jetrna bolezen ali sočasno jemanje hepatotoksičnih zdravil. Pri teh bolnikih je treba zato preveriti o rednem spremljanju jetrnega delovanja. Dajanje zdravila Tarceva je treba prekiniti, če so spremembe jetrnega delovanja hude. Tablete vsebujejo laktazo in jih ne smemo dajati bolnikom z redkimi dednimi stanji: intoleranco za galaktozo, laktazo pomanjkljivostjo ali malabsorpcijo glukoze/galaktoze.

Medsebojno delovanje z drugimi zdravili in druge oblike interakcije: Erlotinib se pri ljudeh presnavlja v jetnih z jetrnimi citokromi, primarno s CYP3A4 in v manjši meri s CYP1A2. Presnova erlotiniba zunaj jeter poteka s CYP3A4 v žrevesju, CYP1A1 v pljučih in CYP1B1 v tumorskih tkivih. Z zdravilnimi učinkovinami, ki se presnavljajo s temi encimi, jih zavirajo ali pa so njihovi induktorji, lahko pride do interakcij. Erlotinib je srednje močan zaviralec CYP3A4 in CYP2C8, kot tudi močan zaviralec glukuronidacije z UGT1A1, in vitro. Pri kombinaciji ciprofloksacina ali močnega zaviralca CYP1A2 (npr. fluvoksamina) z erlotinibom je potrebna previdnost. V primeru pojavnosti neželenih dogodkov, povezanih z erlotinibom, lahko odmerek erlotiniba zmanjšamo. Predhodno ali sočasno zdravljenje z zdravilom Tarceva ni sprejelo odčitka protitipov substratov CYP3A4, modulatorja in erlotinibona. Inhibicija glukuronidacije lahko povzroči interakcije z zdravili, ki so substrati (UGT1A1) in se zloščajo samo po tej poti. Močni zaviralci aktivnosti CYP3A4 zmanjšajo presnovo erlotiniba in zvečajo koncentracije erlotiniba v plazmi. Pri sočasnem jemanju erlotiniba in močnih zaviralcev CYP3A4 je zato potrebna previdnost. Če je treba, odmerek erlotiniba zmanjšamo, še posebno pri pojavi toksičnosti. Močni spodbujevalci aktivnosti CYP3A4 zvečajo presnovo erlotiniba in pomembno zmanjšajo plazemske koncentracije erlotiniba. Sočasno dajanje zdravila Tarceva in induktorjev CYP3A4 se je treba izogibati. Pri bolnikih, ki potrebujejo sočasno zdravljenje z zdravilom Tarceva in močnim induktorjem CYP3A4 je treba preveriti ali povečanju odmerka do 300 mg ob skrbnem spremljanju njihove varnosti. Zmanjšana izpostavljenost se lahko pojavi tudi z drugimi induktorji, kot so fenitoin, karbamazepin, barbiturati ali fenitoin. Če te zdravilne učinkovine kombiniramo z erlotinibom, je potrebna previdnost. Kadarkoli je mogoče, je treba razmisli o drugih načinih zdravljenja, ki ne vključujejo močnega spodbujanja aktivnosti CYP3A4.

Bolnikom, ki jemljejo varfarin ali druge kumarinske antikoagulate, je treba redno kontrolirati protrombinski čas ali INR. Sočasna uporaba zaviralcev P-glikoproteina, kot sta ciklosporin in verapamil, lahko vodi v spremenjeno porazdelitev in/ali spremenjeno zloščanje erlotiniba. Za erlotinib je značilno zmanjšanje točnosti pri pH nad 5. Zdravila, ki spreminjajo pH v zgornjem delu prebavil, kot so zaviralci protonске črpalke, H2 antagonisti in antiacidi, lahko spreminjajo točnost erlotiniba in posledično njegovo biološko uporabnost. Kombinaciji erlotiniba in zaviralcev protonске črpalke se je treba izogibati. Učinki sočasnega dajanja erlotiniba in H2 antagonistov ali antiacidov niso znani, vendar je zmanjšana biološka uporabnost verjetna. Zato se je treba sočasnemu dajanju teh kombinacij izogibati. V študiji faze Ib ni bilo pomembnih učinkov gemcitabina na farmakokinetiko erlotiniba, prav tako ni bilo pomembnih učinkov erlotiniba na farmakokinetiko gemcitabina. Erlotinib poveča koncentracijo platinе. Pomembnih učinkov karboplatina ali paklitaksela na farmakokinetiko erlotiniba ni bilo. Kaptecitabin lahko poveča koncentracijo erlotiniba. Pomembnih učinkov erlotiniba na farmakokinetiko kaptecitabina ni bilo.

Neželeni učinki: Zelo pogosti neželeni učinki so kožni izpuščaj in driska, kot tudi utrujenost, anoreksija, dispneja, kašelj, okužba, navzeja, bruhanje, stomatitis, bolečina v trebuhu, pruritus, suha koža, suhi kašelj, konjunktivitis, konjunktivitis, zmanjšanje telesne mase, depresija, glavobol, nevralgija, dispneja, flatulenca, alopecija, okorelost, preksija. Pogosti neželeni učinki so gastrointestinalna kravatitva, krvavitve iz nosu, neormalnosti testov jetrne funkcije, keratitis, zmanjšanje. Redko so poročali o jetrni odpovedi. Običajno pa o poročanosti moškega tipa pri ženskah, spremembah trepanic/obnvi, krčkih nohtih, odstopanju odbov od kože, nesni intersticijski pljučni bolezni, vključno s smrtnimi primeri.

Režim izdaje zdravila: H/Ro

Imetnik dovoljenja za promet: Roche Registration Limited, 6 Falcon Way, Shire Park, Welwyn Garden City AL7 1TW, Wilks, Britanija

Informacija pripravljena: 1. april 2008.

DODATNE INFORMACIJE SO NA VOLJO PRI Roche farmacevtska družba d.o.o. Vodovodna cesta 109, 1000 Ljubljana. Povzetek glavnih značilnosti zdravila je dosegljiv na www.roche.si.

ČAS ZA ŽIVLJENJE.

DOKAZANO PODALJŠA PREŽIVETJE PRI BOLNIKI¹:

- z lokalno napreduvalim ali metastatskim nedrobnoceličnim rakom pljuč¹
- z metastatskim rakom trebušne slinavke¹

¹ Povzetek glavnih značilnosti zdravlja TARCEVA, www.emea.europa.eu

Že desetletje prinašamo rešitve v Vaš laboratorij!

Za področja:

- bioznanosti **SYNGENE, INVITROGEN:**
DYNAL, ZYMED, MOLECULAR PROBES, CALTAG
- diagnostike **MINERVA, MEDAC, BIOTEK**
- gojenja celičnih kultur **INVITROGEN-GIBCO,**
TPP, GREINER in SANYO
- merjenja absorbance, fluorescence in luminiscence **BIOTEK**
- pipetiranja **BIOHIT in BIOTEK**
- laboratorijske opreme **SANYO**
- čiste vode za laboratorije **ELGA LABWATER**
- HPLC in GC kolon, vial in filtrov **PHENOMENEX in**
CHROMACOL/NATIONAL SCIENTIFIC

KEMOMED
*Prinašamo
rešitve*

TANTUM® VERDE

(benzidamin)

**Lajša lokalizirano bolečino
in oteklino pri vnetju v ustih in žrelu!**

BLAŽI ZNAKE VNETJA

- ◆ Zmanjšuje oteklino

HITRO UMIRI BOLEČINO

- ◆ Zmanjšuje težave pri požiranju

TANTUM VERDE

- ◆ učinkovit in enostaven za uporabo ter varen;
- ◆ brez sladkorja, primeren tudi za diabetike;
- ◆ primeren za otroke, starejše od 6 let.

IMETRIX DOVOLJENJA ZA PROMET

TANTUM® VERDE se prodaja brez recepta v lekarnah! Dodatne informacije dobite pri imetniku dovoljenja za promet.

Pred uporabo natančno preberite navodilo! O tveganju in neželenih učinkih se posvetujte z zdravnikom ali s farmacevtom.

gelclair®

**UČINKOVITO, DOLGOTRAJNO OLAJŠANJE BOLEČIN
ZA BOLNIKE Z ORALNIM MUKOZITISOM**

GELCLAIR® je bioadherenten gel za oralno uporabo. Prekrije sluznico v ustni votlini in žrelu ter tako ustvari zaščitno plast, ki za več ur pomiri oralni mukozitis. GELCLAIR® odlikuje enostavna uporaba in zelo dobra prenosljivost, brez zabeleženih neželenih stranskih učinkov in interakcij z zdravili.

 **HELSINN**

 **PharmaSwiss**

NOVO

NAVELBINE®

vinorelbin

Koncentrat za raztopino za infundiranje 10 mg/ml, 50 mg/5ml

Novost za zdravljenje: nedrobnoceličnega raka pljuč in napredovalega raka dojke

Izkušnje z
več kot
1 mio bolnikov
po svetu

Zdravljenje po meri bolnika!

- Odlična učinkovitost v kombinaciji s cisplatinom ali kot monoterapija za bolnike, ki niso primerni za polikemoterapijo
- Dobra prenosljivost:
 - blaga alopecija
 - zelo nizka stopnja emetogenosti (< 10 %)
 - ni kardiotsičnosti
 - ni nevrotoksičnosti
- Premedikacija ni potrebna
- Sinergistično delovanje s tarčnim zdravilom trastuzumab

Pred predpisovanjem zdravila Navelbine® preberite povzetek tasejnih značilnosti, ki ga dobite pri naših strokovnih sodelavcih.

Editorial policy

Editorial policy of the journal *Radiology and Oncology* is to publish original scientific papers, professional papers, review articles, case reports and varia (editorials, reviews, short communications, professional information, book reviews, letters, etc.) pertinent to diagnostic and interventional radiology, computerized tomography, magnetic resonance, ultrasound, nuclear medicine, radiotherapy, clinical and experimental oncology, radiobiology, radiophysics and radiation protection. The Editorial Board requires that the paper has not been published or submitted for publication elsewhere: the authors are responsible for all statements in their papers. Accepted articles become the property of the journal and therefore cannot be published elsewhere without written permission from the editorial board. Papers concerning the work on humans, must comply with the principles of the declaration of Helsinki (1964). The approval of the ethical committee must then be stated on the manuscript. Papers with questionable justification will be rejected.

Manuscript written in English should be submitted to the Editorial Office in triplicate (the original and two copies), including the illustrations: *Radiology and Oncology*, Institute of Oncology, Zaloska 2, SI-1000 Ljubljana, Slovenia; (Phone: +386 (0)1 5879 369, Tel./Fax: +386 (0)1 5879 434, E-mail: gsera@onko-i.si). Authors are also asked to submit their manuscripts electronically, either by E-mail or on CD rom. The type of computer and word-processing package should be specified (Word for Windows is preferred).

All articles are subjected to editorial review and review by independent referee

selected by the editorial board. Manuscripts which do not comply with the technical requirements stated herein will be returned to the authors for correction before peer-review. Rejected manuscripts are generally returned to authors, however, the journal cannot be held responsible for their loss. The editorial board reserves the right to ask authors to make appropriate changes in the contents as well as grammatical and stylistic corrections when necessary. The expenses of additional editorial work and requests for reprints will be charged to the authors.

General instructions • Radiology and Oncology will consider manuscripts prepared according to the Vancouver Agreement (*N Engl J Med* 1991; **324**: 424-8, *BMJ* 1991; **302**: 6772; *JAMA* 1997; **277**: 927-34.). Type the manuscript double spaced on one side with a 4 cm margin at the top and left hand side of the sheet. Write the paper in grammatically and stylistically correct language. Avoid abbreviations unless previously explained. The technical data should conform to the SI system. The manuscript, including the references may not exceed 20 typewritten pages, and the number of figures and tables is limited to 8. If appropriate, organize the text so that it includes: Introduction, Material and methods, Results and Discussion. Exceptionally, the results and discussion can be combined in a single section. Start each section on a new page, and number each page consecutively with Arabic numerals.

Title page should include a concise and informative title, followed by the full name(s) of the author(s); the institutional affiliation of each author; the name and address of the corresponding author (includ-

ing telephone, fax and e-mail), and an abbreviated title. This should be followed by the *abstract page*, summarising in less than 200 words the reasons for the study, experimental approach, the major findings (with specific data if possible), and the principal conclusions, and providing 3-6 key words for indexing purposes. The text of the report should then proceed as follows:

Introduction should state the purpose of the article and summarize the rationale for the study or observation, citing only the essential references and stating the aim of the study.

Material and methods should provide enough information to enable experiments to be repeated. New methods should be described in detail. Reports on human and animal subjects should include a statement that ethical approval of the study was obtained.

Results should be presented clearly and concisely without repeating the data in the tables and figures. Emphasis should be on clear and precise presentation of results and their significance in relation to the aim of the investigation.

Discussion should explain the results rather than simply repeating them and interpret their significance and draw conclusions. It should review the results of the study in the light of previously published work.

Illustrations and tables must be numbered and referred to in the text, with appropriate location indicated in the text margin. Illustrations must be labelled on the back with the author's name, figure number and orientation, and should be accompanied by a descriptive legend on a separate page. Line drawings should be supplied in a form suitable for high-quality reproduction. Photographs should be glossy prints of high quality with as much

contrast as the subject allows. They should be cropped as close as possible to the area of interest. In photographs mask the identities of the patients. Tables should be typed double spaced, with descriptive title and, if appropriate, units of numerical measurements included in column heading.

References must be numbered in the order in which they appear in the text and their corresponding numbers quoted in the text. Authors are responsible for the accuracy of their references. References to the Abstracts and Letters to the Editor must be identified as such. Citation of papers in preparation, or submitted for publication, unpublished observations, and personal communications should not be included in the reference list. If essential, such material may be incorporated in the appropriate place in the text. References follow the style of Index Medicus. All authors should be listed when their number does not exceed six; when there are seven or more authors, the first six listed are followed by "et al". The following are some examples of references from articles, books and book chapters:

Dent RAG, Cole P. *In vitro* maturation of monocytes in squamous carcinoma of the lung. *Br J Cancer* 1981; **43**: 486-95.

Chapman S, Nakielny R. *A guide to radiological procedures*. London: Bailliere Tindall; 1986.

Evans R, Alexander P. Mechanisms of extracellular killing of nucleated mammalian cells by macrophages. In: Nelson DS, editor. *Immunobiology of macrophage*. New York: Academic Press; 1976. p. 45-74.

Page proofs will be faxed or sent by E-mail to the corresponding author. It is their responsibility to check the proofs carefully and fax a list of essential corrections to the editorial office within 48 hours of receipt. If corrections are not received by the stated deadline, proof-reading will be carried out by the editors.
